PHOTOGRAPHY. While the invention of photography is properly dated at 1839, the year when Daguerre's remarkable process was published by the French government, it is perhaps unjust not to give additional credit to the work of many other men whose efforts in this direction can be traced back hundreds of years.

The basic idea of the camera was known long before the time of Daguerre, and its principles seem to have been understood by Aristotle in his writings published about 350 B.C. The first clear description of the camera obscura is found in an account of Leonardo da Vinci, who wrote: «when the images of illuminated objects enter into a very dark chamber by a small, round aperture, if you receive these images in the interior of the room on a piece of white paper placed at some distance from the aperture, you will notice on the paper all the objects in their proper forms and colors: they will be lessened in size and will be reversed, and that in virtue of the intersection already noticed.» There are other vague references to the construction and use of the camera obscura in these early years, so that it seems probable that it was known at least as a curiosity by some of the learned men of the time.

However, widespread knowledge of the camera obscura did not come until the latter part of the sixteenth century after the publication of «Magia Naturalis» by Giovanni Battista della Porta, in which there was a description of the phenomenon. Shortly afterward, a lens was employed in the camera obscura by the Venetian, Daniello Barbaro, so that as early as the beginning of the seventeenth century, the means was available to form a camera image, if not to record it. In fact, small, portable models of the camera obscura, which were introduced somewhat later, with a mirror that made them look not dissimilar to a rough likeness of a modern reflex camera, were used considerably by artists and those learning to paint. It is interesting to observe that two of the men responsible for the early perfection of photography, Daguerre and Talbot, were both spurred on to their accomplishments by the desire to capture the image formed in the camera obscura.

Records of the photo-chemical action of light go back about as far as the observation of the principle of the camera. Aristotle noticed the effect of light in forming the green coloring matter of plants, and some eleven hundred years later, in the eighth century, the Arabian alchemist, Geber, noted that silver nitrate became dark on exposure to the atmosphere. However, the first definite recognition of the action of light in darkening silver salts must be attributed to Johann Heinrich Schulze, who, in 1727, noticed that a mixture of chalk and aqua regia assumed a dark purple color on the surface exposed to light. Further experimenting by Schulze proved the coloration was due to the presence of a small amount of silver. Some fifty years later, Carl Wilhelm Scheele extended the knowledge of this reaction by finding that silver nitrate was more sensitive to blue and violet light than it was to other colors of the spectrum. Scheele also made the important discovery that the darkening of silver chloride upon exposure to light released small amounts of chlorine.

The word «photography» is derived from two Greek words—«phos,» meaning light, and «graphein,» meaning to write. By the end of the eighteenth century, materials were on hand which would permit man to write with light, but in adapting them to meet the specialized requirements, there were still much hard work and patience required. It must be remembered, of course, that previous to this time, the development of the camera obscura and the observations on the sensitivity of certain materials to light had been carried out as entirely independent ideas and it was not until the beginning of the nineteenth century that workers began to see the opportunity provided for the practical application of what already had been learned. Thomas Wedgwood, a young Englishman who worked with the chemist, Sir Humphrey Davy, investigated the experiments of Schulze and succeeded in making prints on paper and leather sensitized with silver nitrate. A pen and ink drawing on glass or a semi-translucent material, like a leaf, was placed on the sensitive material with a resulting shadowgram being produced upon exposure to light. Wedgwood and Davy reported their findings to the Royal Institute in 1802 but were unable to make the material sensitive enough for use in the camera obscura or to make the resulting prints permanent and free from change upon further exposure to light.

The first permanent photograph made with a camera is generally believed to have been made by Joseph Nicéphore Niépce, who worked from 1816 to 1829 in the quest of further perfecting his process. That year, Niépce formed a partnership with Louis Jacques Mandé Daguerre, a well-known French diorama painter,

who had been working independently for several years on the problem of recording the image produced by the camera obscura and who had approached Niépce as early as 1827 with the suggestion of collaborating on the problem. After Niépce's death in 1833, Daguerre greatly modified and advanced the original process and Niépce's son, Joseph Isidore, who had succeeded him in the partnership, agreed to give Daguerre rights to the new process. The two then tried unsuccessfully to sell the new process by public subscription. Publication of the process came in 1839 after the famous physicist, Arago, had interceded and interested the French government to the extent of authorizing an annunity to Daguerre and Niépce so that the process could be made public.

The original process of Niépce, which had been termed «heliography,» depended upon sensitivity to light of bitumen which was coated on a metal plate. Exposed parts became insoluble while unexposed parts were easily removed with lavender oil, thus leaving bare the surface of the metal which could be etched with acid to give a relief for printing purposes. This, of course, was a form of photo-engraving, but Niépce repeated the same process in a camera using a glass support instead of metal, and obtained a negative image of the original which could be viewed by transmitted light or converted to a positive by repeating the process.

The Daguerreotype process involved the use of a polished silver plate which was treated with the fumes of iodine to form a microscopically thin layer of silver iodide on its surface. After exposure, the plate was placed in a closed box over a dish of heated mercury. The mercury vapor brought out the image and made it visible by uniting with the exposed parts to form an amalgam. The plate was made permanent by treating it with a common salt solution which removed the unexposed portion of the sensitive layer. Further modifications were the employment of silver-plated copper for the Daguerreotype plates and the use of «hypo» (sodium thiosulphate), for which Sir John Herschel must be credited with the discovery of both the chemical and its solvent action on silver salts. Exposures in bright light were of the order of three or four minutes, but with the introduction of the Petzval portrait lens and the discovery by the Englishman, Goddard, and the Austrian Kratochwila, that a mixture of bromine and iodine was more effective as the sensitizing agent, exposures were reduced to the point where portraits could be made in bright light.

As the first commercially successful form of photography, the Daguerreotype was a significant invention of its day. Even if it had not been first, the Daguerreotype would still be important for the tremendous effect it had in promoting an intense, widespread interest in picture-taking. Both abroad and in this country, there was immediate acceptance of the Daguerreotype process after the first wave of unbelief had passed, and everywhere individuals took a lively interest in finding out about the new process and experimenting with it. Daguerre's original pamphlet, which gave the process and apparatus that was necessary, was printed to the extent of 29 editions (six in France, nine in Germany, three in Great Britain, one in United States, etc.).

It is interesting to note that Prof. Samuel F. B. Morse, famed for his invention of the telegraph, was also an enthusiastic experimenter in the new process. Morse had seen Daguerre in Paris in the spring of 1839 and then returned to the United States in the early fall, just about the time the news of the working details of the Daguerreotype process was being received in America. He actively supported the promotion of Daguerreotypes and taught many how to use the equipment which was necessary. One of his earliest students was Edward Anthony, who later established a photographic supply house that eventually became one of the country's leading photographic manufacturers. One of Morse's associates was John W. Draper, to whom is generally credited the honor of having made the first portrait in this country. Daguerreotypists appeared everywhere and such workers as J. J. Hawes, Langenheim Brothers, John A. Whipple, Matthew B. Brady, M. M. Lawrence and Meade Brothers are still remembered by some of the outstanding Daguerreotypes they produced. In spite of its faults, which included reversal from left to right of the image, harshness of tone, lack of color sensitivity and the inability to produce duplicates, the Daguerreotype, nevertheless, was one of the most important motivators in the development of photography.

Contemporary with Daguerre and Niépce was the Englishman, William Henry Fox Talbot, who pioneered in his own way and who, although failing the immediate recognition and success which was accorded Daguerre, nevertheless came much closer in his achievements to the modern methods of photography which were subsequently adopted. Talbot started in 1834 to find a way to record permanently the image in his camera obscura. Repeating the experiments of Schulze and Wedgwood, Talbot finally succeeded in recording an image in 1835 by using a paper which had been treated successively with solutions of silver nitrate and potassium iodide and which was exposed while wet. He also found that the print could be made permanent by washing with salt water. Further refinements resulted in the Calotype process in 1840 (also known as «Talbotype»), which employed paper sensitized with silver iodide. Before and after the exposure, the paper was bathed in a solution of gallic acid and silver nitrate, which developed the invisible, latent image formed during exposure. This produced a negative, and Talbot found that after fixing and drying the original image, any number of copies could be made on sheets of similarly sensitized paper which would be positive duplicates of the original.

Talbot's process was important because it overcame many of the defects inherent in the Daguerreotype. It permitted the production of duplicates, it corrected the left-to-right reversal of the image, and it was, in some respects, easier to handle. These advantages were, at the same time, counterbalanced by the faults of low sensitivity and poor reproduction of details because of the grain of the paper introduced into the final picture by the negative. Furthermore, Talbot's process, while little used in comparison with the widespread employment of the Daguerreotype by photographers of that period, opened the way to important improvements in the negative-positive process.

Photographed on Agfa film

"Flying Spinnakers," one of the most remarkable marine photographs of recent years.

Photographed on Agfa film

An expressive study of animal life.

The first steps in this direction were the attempts of Niépce de Saint Victor (nephew of the original Niépce), Blanquart-Evrard and Gustave Le Gray to eliminate the effect of the paper texture in the final print. However, their methods, which included waxing the paper negative, placing it while wet between two sheets of glass, or using albumen to bind the silver salts to a glass support, were not the final answer. One of the suggestions of Le Gray involved the use of collodion as a support for the sensitized material, and this was further perfected and established as a practical form of photography by the Englishman, Frederick Scott Archer, who reported on his collodion process in 1851.

Scott Archer's collodion process is one of the outstanding developments in the perfection of photography, and despite its many disadvantages, served as the most satisfactory method for over twenty years. It is, in fact, still used in a slightly modified way by photo-engravers. The principle of his method was to coat a clean sheet of glass with a thin layer of collodion containing, in addition to its mixture of guncotton, ether and alcohol, a small amount of some halide salt such as potassium iodide. Before the collodion film was completely dry, the plate was immersed in a silver nitrate solution and then removed to the camera and exposed while still wet. After exposure, the image was brought out by development in a solution of some reducing agent, such as ferrous sulphate or pyrogallic acid.

As can be imagined, this procedure was one which required a great degree of care and accuracy and, in addition, involved the preparation of plates on the spot, necessitating the use of considerable bulky and cumbersome equipment. In spite of these objections, the collodion process offered such advantages that it rapidly replaced both Daguerreotypes and the various paper negative processes which were employed until nearly 1860. For the next 15 or 20 years, the collodion process reigned supreme, for the reduction of exposure which it permitted and the ability to make any number of paper prints with clean, sharp detail, were advantages that could not be matched by any other process. Even the miniatures and small, framed pictures for which the Daguerreotype was so ideally suited, were replaced by a form of the wet collodion process called the Ambrotype. By this method, the silver deposits of the glass negative were whitened by mercuric chloride and black paint applied to the back of the glass to provide the necessary dark background for the shadows.

With the collodion process, the scope of photography began to increase and develop fields other than the simple portraiture and still-life photography to which Daguerreotypes and paper negatives were limited. One of the outstanding examples of this extension of subject range is evident in the extensive photographic work carried out during the Civil War by a number of active photographers. Best known of these workers is probably Matthew Brady who, with his assistants, had taken over 7,000 pictures by the end of the war.

The handicap of the collodion process which was undoubtedly most troublesome to photographers of that day was the necessity for preparing the wet plate at the time and place where the exposure was to be made. As a result, much effort was expended in this period toward eliminating this difficulty, and many were the suggestions for special substances and strange formulas which would keep the collodion plates moist and sensitive over longer periods of time. However, no one of these was entirely satisfactory and it wasn't until 1871 that a successful answer to the problem was discovered. The inventor of the new process was an amateur photographer, Dr. R. L. Maddox, and his innovation was the use of gelatin as a binding material in which the light-sensitive salts were formed. The employment of gelatin as a binding agent for the sensitive salts is recorded in such early attempts as that of Niépce de Saint Victor in 1847, Gaudin in 1853, Norris in 1856 and several others who preceded Dr. Maddox. Yet all of these predecessors failed of the complete success which Maddox achieved. By his method the sensitive silver bromide was formed in a solution of gelatin and the mixture coated on plates and allowed to dry. No further sensitizing was employed and the plates could be used days and even weeks after they were prepared.

Practical as his method was, Dr. Maddox' process was not immediately adopted, but in the next few years, a general swing to gelatin dry plates occurred as further improvements were made by other workers who found that washing by-products from the gelatin before coating and that treating the gelatin emulsion with heat or with ammonia resulted in noteworthy gains in sensitivity. Such improvements as the removal of free silver by King in 1873, the heat treatment of emulsions in 1878 by Bennett and the ammonia treatment by Monkhoven in 1879, were responsible for an increase in available emulsion speed of from 30 to 50 times over that previously offered by the collodion process.

Another noteworthy discovery of this period was that of H. W. Vogel who found that the treatment of an emulsion with a solution of certain dyestuffs would extend its sensitivity to colors other than violet, blue and blue-green, to which silver halide emulsions are basically sensitive. Vogel's discovery was not applied commercially to any extent for a number of years, but it is still an important milestone in the development of photographic materials as it made possible the improved tone recording of colored objects and furthered the search for other color sensitizers which extended the sensitivity of photographic materials to all colors of the spectrum. The perfection of panchromatic materials, sensitive to all colors, was an improvement necessary to the basic pioneering in color photography done by such workers as Maxwell, Joly, Lumiere and Ives. (See COLOR PHOTOGRAPHY).

Soon after the perfection of the gelatin process, dry-plates were produced commercially, the Liverpool Dry Plate Company and Wratten and Wainright being the earliest manufacturers in England, and Carbutt in the United States. This was a tremendous impetus to the broadening of the interest in photography among non-professionals, for while it greatly simplified the darkroom work done by the professional, it made it possible for the amateur to attempt photography as a hobby, where he would never before have dared to meet the cost and trouble of picture-taking with the extensive and cum-

bersome equipment necessary for the wet collodion process.

The commercial availability of gelatin dry plates and the growing interest among would-be amateur photographers emphasized the desirability of smaller cameras. With the increased speed provided by gelatin dry-plates, it was no longer necessary to use a tripod for time exposures, as a short instantaneous exposure could be made with a camera held by hand. One of the first practical hand cameras of this sort was introduced by E. & H. T. Anthony Company of New York in 1884 and provided a small finder, a shutter with adjustable speeds, arrangements for focusing the lens for near and far distances, and a receptacle in the back which received plate holders. Many variations of this basic idea were produced, with most cameras taking plates of about 4x5 in. in size, although some went up to 5x7 in. and some to 3x4 in. or smaller. Because of the novelty of such small equipment and its compactness, which would not be identified in the minds of the laymen of that day with ordinary camera equipment, any camera of this sort which took pictures 5x7 in. in size or smaller, was frequently termed a «detective» camera — a sidelight on early equipment which seems amusing to the modern amateur for whom the most popular size is usually 2¼x3¼ in. One of the smaller hand cameras produced in the early years was that marketed by George Eastman of Rochester, N. Y., in 1888. Called the «kodak,» the Eastman camera was unique in that it was loaded at the factory with a roll of sensitized paper, the entire outfit being returned to the manufacturer for development when the roll was completely exposed. Each roll, upon development, gave a long strip of paper negatives from which about 100 different pictures could be obtained.

With the growing interest in smaller cameras and the desirability for portable equipment, there was a strong desire evidenced by many photographers for some substitute for the heavy, fragile glass plates which were then in current use. The obvious substitute for glass was some support which was clear, light and unbreakable. First among the many workers who were searching for such a material was an amateur photographer, the Rev. Hannibal Goodwin, of Newark, N. J., who, in 1887, obtained a patent on a thin, rollable, transparent film which could be used as a satisfactory substitute for glass to support the photographic emulsion. The Goodwin patent was assigned to E. and H. T. Anthony who marketed the film. This invention of flexible film paved the way to the widespread use of cameras by amateurs, for it simplified the work of picture-taking and made it possible to use cameras which were compact and portable. The applications of this invention of Goodwin's were not, however, restricted merely to the amateur field, for with the thin, rollable base, the motion picture became a possibility where before it had been an inventor's dream.

The earliest experiments in the study of motion photography were those of Edward Muybridge, who succeeded in photographing a horse in full gallop, as well as other moving objects, by a series of cameras operated one after the other, to give a succession of pictures that could be used in the analysis of the motion. The development of this idea into the practical motion-picture camera and projector did not come until 1896, after the Lumiere Brothers, as well as Armat, Jenkins, Edison and several others had given it much work and thought.

In other fields too, older methods have been superseded by the use of photographic film prepared in various sizes and types of packing. Sheets of cut film and film packs are now almost universally used in place of glass plates by news, professional and commercial photographers. Glass dry-plates, at the present time, are in use to a very restricted extent, and are employed primarily by astronomical photographers and by other workers who require an extremely flat surface in which there is no possible chance of expansion or shrinkage. As mentioned above, wet collodion plates are used only in the photo-engraving trade to any extent. (See PHOTO-ENGRAVING).

In the past twenty years, photography has matured tremendously and emerged as a vital force in the business, art and science of this country. There have been innumerable technical improvements which have repeatedly extended the scope and usefulness of photographic materials throughout the range of human activities. These refinements have not been restricted to one particular type of photographic materials but are evident in sensitized products like films and papers, and in the wide variety of cameras, projectors and associated equipment. Photographic films, for example, have been made extremely versatile in their performance and capabilities with a wide variety of individual types available for specialized uses. Photographic film speed, in general, has been notably increased and special, super-sensitive films of extreme speed have appeared on the commercial market as the result of notable advances in the science of preparing photographic emulsions. At the same time, other technical characteristics, such as gradation, grain size and color sensitivity, have been refined and brought to higher standards than it was dreamed possible to achieve some 25 years ago.

Photographic films are prepared in a number of different sizes and types to meet the wide variety of uses and the several different, basic camera sizes in use. Roll films are prepared primarily for amateur hand cameras; film packs for folding cameras of a slightly more advanced type; cut (sheet) films for professional cameras; 35-mm. miniature films for the popular cameras of small size that are designed to take professional 35-mm. stock similar to that used by professional motion picture cameras; and motion picture film in both 35-mm. (professional) and 8-mm. and 16-mm. (amateur) sizes. The types of film available in these basic sizes are not the same in all cases, but there are usually representative types in each size group so that the user may choose:

1. A film which offers extreme speed, important when there is little light available or when photographs must be made at small lens openings with fast shutter speeds.

2. A film with fine grain, desirable when small cameras are used so that large-sized projection prints may be made which do not reveal the structure of the silver deposits which make up the original negative image.

3. A high-speed film of moderately fine grain, which is a compromise between the two aforementioned extremes.

sold today is panchromatic, that is, sensitive to all colors and balanced in sensitivity so that the monochrome rendering of the brilliance of each color appears most satisfactory to the human eye. There are, in addition:

1. Orthochromatic films, which are sensitive to all colors except spectral red and which are used primarily for landscape and other outdoor subjects, and, to some extent, for professional portraiture. The insensitivity to spectral red, characteristic of this type of film, is considered an advantage by many photographers as it makes it possible to handle the film safely in weak red light during development.

2. Non-color-sensitized films, which possess only the normal sensitivity to violet and blue of a silver halide emulsion and which are used primarily for the production of motion-picture release prints and for film transparencies such as X-ray films.

3. Infra-red films, which have a sensitivity to violet and blue, possessed by all silver halide emulsions, but, in addition, possess sensitivity to radiations lying beyond the red end of the spectrum, and which are, therefore, useful for special purposes such as penetrating haze. When infra-red film is exposed with a red filter, which absorbs other colors to which the film is sensitive, the image is recorded with these infra-red radiations and the resulting photograph reveals an unusual interpretation of tone values. Blue skies appear dark, clouds are brilliantly white, whereas foliage and green vegetation containing chlorophyl record in light tones of gray. For this reason, infra-red film is extensively used by motion picture photographers to produce night-effect scenes in direct sunlight, and by pictorial photographers to achieve powerful, dramatic sky tones and unusual interpretation of otherwise ordinary subjects.

4. There is also another type of film, called reversible film, used primarily for 8-mm. and 16-mm. amateur motion picture cameras because of the saving of film costs it provides when duplicates are not needed. It differs from other photographic films in that the film originally exposed in the camera is developed by a special process to a positive which is used for projection as a motion picture, thus eliminating one step of the negative-positive process. The process usually employed includes development of the negative image, removal or «bleaching» of the negative image, exposure to bright light and «second» development of the remaining silver halide to form the positive image. Appropriate washing and supplementary solutions are also used.

Photographic papers have been tremendously improved so that they provide great accuracy of tone recording, a wide variety of attractive surfaces, as well as improved technical characteristics, which make for greater dependability and more simplified use. Photographic papers are usually provided in three basic types, of which (1) the silver-chloride papers are used for contact printing, (2) silver-bromide papers for enlargements, and (3) the chloro-bromide papers for both contact and projection printing, especially when warm, rich tones are desired.

Cameras have been made smaller and more compact, more precise, more automatic and more foolproof. In addition to this, their average cost is far under what even a roughly comparable size would have been 20 years ago, discounting the other improvements that have been made. Cost ranges today anywhere from a dollar to a dollar-and-a-half for a good, but simple, box camera that will turn out satisfactory pictures for a beginner, to the four or five hundred dollars needed to buy a professional or advanced amateur's «still» camera with its more capable lens and shutter equipment and higher degree of precision construction. Amateur motion picture cameras may be obtained for as little as $20 to $30, while the cost of professional camera equipment may run into thousands of dollars. This wide range has done much to bring the pleasure of photography to millions of people in every walk of life.

With the perfection of the numerous, highly specialized types of photographic materials that are available today, there has come a necessity for extreme care and precision in manufacturing operations. The preparation of sensitized materials (film and paper) is especially demanding of utter cleanliness, exacting control and repeated testing. While it is impractical to consider here in detail the operations used in the manufacture of sensitized products, the abbreviated description that follows will help to show the methods used.

Photographic film consists of a thin, transparent, flexible base of cellulose nitrate or cellulose acetate which has been coated with a light-sensitive emulsion. The primary raw material of the base is cotton, which is transformed by treatment with acids into the required cellulose nitrate or cellulose acetate (according to type of film base desired — regular or non-inflammable). The treated cellulose is then dissolved in solvents to form a heavy, viscous liquid which, after filtering, is spread evenly in a thin layer on a moving belt where transformation into the flexible band is effected upon the removal of the volatile solvents. The photographic emulsion, which is a dispersion of finely divided silver halide particles in gelatin, is prepared in near darkness by the addition of silver nitrate to a solution of gelatin containing the necessary halide salt. After being chilled to form a jelly, the emulsion is shredded and carefully washed to remove water-soluble by-products. Special treatment called «ripening» is sometimes used and small amounts of other chemicals added to further increase the normal light sensitivity of the emulsion.

The application of the emulsion to the film base is accomplished in the coating operation, by which a thin, even layer of the light-sensitive material is spread over the surface of the base with extreme accuracy. The coated film is then immediately chilled and allowed to dry under closely controlled conditions of temperature and humidity, after which it is ready for cutting and slitting into desired sizes.

Photographic papers are prepared in a somewhat similar manner, the main differences in the process being the use of a very pure paper stock as the support for the emulsion. Further dissimilarities exist in the character of the emulsion layer, which is considerably less sensitive to light than that used for film. In a general way, however, manufacturing operations are similar for both types of products.

The versatility and diversification of modern photographic materials and equipment has resulted in their use in practically every phase of man's activities. Modern photography, it seems,

plays an important part in recreation, education, journalism, and in a vast number of other applications from aerial photography to medical and scientific work. The making of portraits, which was perhaps the first real application of Daguerreotypes, is still an important part of the photographic trade. However, there are other applications which, in many ways, overshadow this basic use.

The motion picture industry itself has become a gigantic business providing employment for thousands, and amusement for millions. In addition, a large degree of the consumption of photographic materials is now accounted for by the amateur photographer who, because of the improvements made in photographic materials, and the satisfaction derived from the hobby, is more in evidence than ever before. News photography has become an important division of journalism and scarcely a newspaper in the country is published without several stories being illustrated by news photographs. Several newspapers have made notable success building their entire appeal through the use of pictures, even to the extent that they dominate the stories. So great an interest in pictures is evidenced by the public at large that a revolutionary trend in magazines has also occurred, with picture magazines which were non-existent a few years ago now rated among the most popular and best read of any. The need for material with which to supply the illustration requirements of magazines and newspapers has, in turn, affected news, commercial and illustration photographers whose professions are now well established, well respected and numbered with thousands of men who have turned to photography as a vocation.

The scientific applications of photography are almost too numerous to mention, with cameras in specialized forms playing a part in almost every field of research. Photomicrographs provide a visual record of minute organisms which may be clearly enlarged for further study, while at the other limit of man's perception, photography helps astronomers to reach out into space and record the presence of stars which the human eye has never seen.

X-ray films have been of tremendous help in diagnosing internal body ailments and, in addition, are being used widely by metallurgists and by manufacturers of castings and other solid objects to detect the presence of interior flaws. The medical profession has additional uses for photography in the preparation of clinical photographs for lecture and educational purposes. Photographs have entered the courts and are frequently valuable evidence in legal work, as well as being extremely helpful to police and governmental bureaus in the identification and record-keeping of criminals.

Photography has entered other fields, being more and more widely used in advertising. Another modern application is the use of photographic film for the recording of documents, books, magazines, newspapers and large quantities of printed material, reduced in size on a small piece of photographic film. By this means, libraries are already saving storage space and finding it possible to preserve a larger quantity of valuable data in the space they have available.

Experiments in spark discharges have shown the feasibility of photographing objects at remarkably short periods of time (as little as 1/1,000,000 of a second), a tremendous extension of Edward Muybridge's original ideas, which will be of great help to science in analyzing motion and rapidly moving objects.

Cameras have plumbed the depths of the ocean, photographing marine life and fish, and have risen to several miles above the earth's surface in free balloons to obtain photographs from the stratosphere. Aerial photography has progressed so far that it is not only in the commercial stage, but is widely adopted by the government for both army and navy purposes and general survey work necessary for accurate mapping.

These are some of the most important applications of photography which give an idea of the extremely versatile nature of this scientific art and of the multitude of ways in which it is serving man, providing him with recreation and amusement, and helping him to do things that would have been considered fantastic and impossible less than fifty years ago.

The business of modern photography presents a complex picture because of the extreme diversification of the many ways in which photography is used. It is extremely difficult, if not impossible, to estimate the number of people who use photography directly or indirectly in their business and daily life. However, some idea of the size of the industry may be obtained from figures compiled by the United States Department of Commerce in connection with their census of United States manufacturers. Figures for 1937 show a total valuation for photographic apparatus and materials produced in the United States of some $115,887,000, an increase of approximately $42,000,000 over the corresponding figure for 1935. The report shows that there were in 1937, in the United States 109 establishments manufacturing photographic materials. The manufacturers of the industry employed approximately 18,000 wage earners, who earned some $28,876,000. These figures pertain only to the manufacturers' activities and do not include or take into consideration others who are engaged in the distribution or selling of photographic products. Nevertheless, the business of servicing consumers of photographic products has grown hand in hand with the photographic industry until it is today an important retail sales activity and the livelihood directly or indirectly of several thousand people. Due to the growing interest on the part of amateurs in picture-taking, photographic departments have been set up in many retail stores to handle the trade in film and finishing. In addition to these, there will usually be found in any fair-sized city, at least one retail store dealing exclusively in photographic materials and associated equipment.

It is difficult to forecast the future of photography and the part it will play in man's activities, but it is fairly safe to say that the use of photography and its usefulness to man is definitely on the increase. The universal interest in pictures, the growing demand for pictures that are real and true to life, seem good reason to believe that photography will become more and more important as the years go on. GLOSSARY OF PHOTOGRAPHIC TERMS

Amalgam—A physical combination of mercury with another metal, such as silver.

Bitumen—A form of pitch used in Niépce's process, "heliography."

Color Sensitivity—The response of a photographic material to various colors of light.

Developer—A solution containing chemicals which acts upon a photographic emulsion, darkening the exposed portions by the formation of metallic silver.

Fine Grain—See Grain Size.

Fixer—A solution of chemicals which converts the unexposed silver halides of a photographic emulsion to soluble salts which are removed by washing.

Focusing—Adjusting the lens-to-film distance on a camera to produce a clear, sharply defined image of the subject.

Gradation—The response of a photographic emulsion to increases in the amounts of exposure. Influenced greatly by the type and extent of development as well as other factors, the inherent gradation of a film emulsion is a major determining factor in the brilliance or contrast obtained in recording the various tones of the image.

Grain Size—The size of the light-sensitive particles present in the photographic emulsion. The related term, fine grain, is used to describe emulsions in which the particle size and distribution are held at values which will make the grain structure of the negative image least noticeable when enlargements of great size are made.

Latent Image—The invisible record formed on a photographic emulsion during exposure, made visible by the action of a developing solution.

Negative—The developed film (or plate) in which the image is reversed in tone, with highlights dark and shadows represented by transparent portions.

Orthochromatic—The term applied to emulsions whose sensitivity has been extended beyond their normal blue and violet sensitivity; the sensitivity of orthochromatic materials usually including all colors except spectral red.

Panchromatic—The term applied to photographic emulsions which are sensitive to all colors of the visible spectrum.

Positive—A photographic print or transparency in which the image tones are presented in the normal manner with shadow portions dark and highlights light.

PHOTOGRAPHY—TELEPHOTOGRAPHY. Telephotography, or the transmission of pictures over distances by means of electrical signals, is an art whose early stages of development extend back to 1842 when Alexander Bain of England devised an electro-chemical recording telegraph system capable of roughly reproducing line drawings. A large number of persons participated in the early research work which has contributed to its development, prominent, among whom, in addition to Bain, were Bakewell, Ayrton, Perry, Bidwell, Caselli, Armstutz, Belin, Baker, and Korn. As early as 1862 a system was in practical use between Paris and Amiens. In 1891 N. S. Armstutz of Valparaiso, Ind., successfully transmitted half-tone pictures, previous reproductions being in black and white, a method requiring much longer transmitting intervals and not practicably capable of as satisfactory reproduction as the half-tone process. By 1910 there was considerable use of picture transmission by the press, particularly in the vicinity of London. The basic principles of telephotography had by this time become well established and recent progress has been largely in improvements in performance and practicability realized through the application of later developments such as the photoelectric cell, vacuum tube amplifiers, electric filters and carrier current. Telephotography has also been furthered by the growth and improvement in wire and radio communication facilities. In recent years telephotograph systems utilizing specially arranged telephone circuits have been made available in North America and Europe, the use of which is almost entirely by press organizations for the transmission of pictures whose news value would be greatly impaired by the delay incurred with physical transportation of the pictures. In the United States the wire communication facilities are provided principally by the Bell Telephone Companies, while transoceanic radio picture transmission service is furnished by the Radio Corporation of America.

The apparatus at the sending end is known as the telephotograph transmitter and its essential function is to scan each elemental area of the picture and impress on the communication circuit electrical signals proportional in intensity (or some other characteristic) to the tone between white and black of each element scanned. For example in one type of system the transmitter consists of a drum rotating at about 100 revolutions per minute on which the picture is mounted and upon which a beam of light is finely focussed. As the cylinder rotates the light moves at a speed of about one inch per minute parallel to the axis of the drum, that is, from the top of the picture to the bottom. This permits scanning the picture from left to right by parallel lines at 100 lines per inch. The light reflected from each picture element over which the beam passes is proportional to the brightness of the element and is in turn focussed on a photoelectric cell which produces an electrical signal proportional to the amount of light striking the cell. These signals are amplified and impressed on a line over which they are transmitted to the receiving equipment.

The telephotograph receiver used with this type of system is much like the transmitter, in that a similar drum is used, rotating at the same speed and a beam of light is focussed through a light valve on a light sensitive film or paper mounted on the drum. As in the transmitter, the light beam moves parallel to the axis of the rotating cylinder at the same speed as that in the transmitter; that is, the beam traverses the drum in a spiral path, scanning the film completely in the same manner as at the transmitter. The signal from the line operates the light valve in such a manner that the light admitted through the valve to the film is proportional to the strength of the incoming electrical signal.

It is essential that the transmitter and receiver drums operate at precisely the same speed and that both beams start at the edge of the original picture and the film at the same instant, In the system described this is accomplished by driving each of the machines from a motor whose speed is locally regulated by a tuning fork. The separate tuning forks in the transmitter and receiver are so accurately adjusted that the slight differences in speed do not noticeably affect the picture. An impulse is transmitted over the circuit to start the transmitter and receiver at the proper instant at the beginning of each picture.

There are other types of equipment which differ in many details from that described par-

ticularly with respect to the method of scanning and the devices used for conversion from light to electric energy and vice versa in the transmitter and receiver respectively.

For satisfactory results the telephotograph equipment and the circuits with which it is used must be designed to work together. The telephone and radiotelegraph circuits used for telephotograph service were designed for other forms of communication. By special modifications, a network of circuits has been provided from the telephone plant exclusively for telephotograph service, which is very satisfactory. With this network and suitably designed terminal equipment, pictures 11 inches by 17 inches can be satisfactorily transmitted in 17 minutes. Ordinary telephone circuits without modification give less satisfactory results, there being danger of distortion of signals, variations in line loss, and disturbances which will not noticeably affect telephone communication but may distort or blemish the reproduced picture. For radio communication, the signal variations due to fading and the noise levels are such that it is necessary to utilize an «on-off» system of transmission in which the duration or number of pulses transmitted, rather than the amplitude of the signal, is proportional to the light intensity.

American Telephone and Telegraph Company.

PHOTOGRAPHY IN COLOR. See COLOR PHOTOGRAPHY.

PHOTOGRAVURE, fō″tō-grā-vūr′, a process of engraving in which, by the aid of photography, subjects are reproduced as plates suited for printing in a copper-plate press. The process known as heliogravure is essentially the same. See PHOTO-ENGRAVING.

PHOTO-GLYPTOGRAPHY, that department of photo-engraving in which the plates are in intaglio. See PHOTO-ENGRAVING.

PHOTOMETRY is the art of comparing the intensity of a source of light with that of another source which is taken as a standard. The possibility of making such comparisons depends upon the power of determining by means of the eye when two neighboring fields of view, illuminated respectively by the two sources in question, are equally bright. The sensitiveness of the eye to inequalities of brightness does not greatly exceed 1 per cent, even under the best conditions; and since it frequently falls below that value from fatigue and from various other causes, numerous attempts have been made to find photometric methods which are independent of this organ, but thus far without much success.

Photometers.—Any instrument for the measurement of the intensity of a source of light is termed photometer. Since all attempts to substitute for the eye such instruments as the thermobile, the bolometer and the selenium cell have, for the ordinary purposes of photometry, led to unsatisfactory results, all existing photometers which have come into general use are based upon the above-mentioned power of the eye. The earliest form, which was originally described by Bouguer, was invented early in the 18th century. It consisted of a screen *AB* (Fig. 1) illuminated by the sources of light *S* and *s*, the intensities of which were to be compared. The partition *PC* prevented the light of *S* from falling upon *BC* and that of *s* from reaching *AC*. The distance of the two sources from the screen was adjusted until the illumination of *AC* appeared to the eye to be equal to that of *BC*.

An ingenious modification of this instrument, devised by Lambert (1760) and subsequently used by Rumford (1794) is known as the

Shadow Photometer or Rumford Photometer.—In this apparatus an opaque body, usually an upright rod (*R*, Fig. 2) is placed in front of the screen. The surface of the screen is illuminated by both sources but the two shadows *AB, CD,* are each illuminated by light from one of the sources exclusively. When these shadows are equally bright the distances of *S* and *s* from the shadows which they illuminate determine the relative intensity of the two sources.

Ritchie (1826) introduced a new principle into photometry. He placed the two lights to be compared at the ends of a track or bar along which a box containing two mirrors *M,M′* (Fig. 3) could be moved, until the rays from *S,* reflected at *M* to the left half of the screen *AB* gave an illumination equal to that from the rays from *s* reflected by *M′* to the other half of the screen. This screen was of some translucent material, usually paper.

Bunsen (1841) substituted for the Ritchie screen a sheet of unsized paper the central, usually circular, portion of which had been rendered translucent by the application of oil or of melted paraffin. The paper when placed between two sources of light, the plane of the paper perpendicular to the incident rays on either side, affords a very simple and convenient means of determining when the illumination from the two sides is equal. When subjected to unequal illumination from the two sides the translucent portion of the face toward the brighter source appears dark, the unoiled portion bright. On the other face the reverse is true (see Fig. 4). As the paper is moved away from the brighter source and toward the weaker an interchange in the appearance of the two surfaces occurs and there is a neutral position in which both appear alike and in which it is scarcely possible to distinguish the translucent portions. When this position has been found the relative intensities of the two sources may be calculated from the law of inverse squares. To facilitate the observations the bar or track upon which the paper screen is mounted is divided into a convenient number of equal parts.

The sheet of paraffined paper, technically known as the Bunsen disc, is usually mounted in a wooden box with blackened walls (the photometer carriage), which slides or rolls along the track between the sources of light. Two small mirrors (*M* and *M′*, Fig. 5), mounted obliquely within the box, enable the operator to observe simultaneously the two faces of the paper (*O.O.*).

The various forms of photometer already described and all others which depend upon the power of the eye to detect slight inequalities of illumination are essentially of equal sensitiveness. They are all limited by the sensitiveness of the eye and approach the maximum degree of delicacy as we fulfil more and more nearly the conditions under which the eye can be used to the best advantage. All forms of the Ritchie and Bunsen photometers, of each of which many modifications have been devised, are, however,

subject to a peculiar source of error. It is found that when two sources of light, the relative intensities of which are known, are compared by means of such photometers, observers will persistently set the instrument to a false position. The majority of observers find apparent equality at a position toward the left-hand source. The errors which are constant for a given observer, however great his experience, range from 1 per cent to 10 per cent. They appear to be analogous to the errors which occur when one endeavors to bisect a straight line by the eye without the use of instruments. The existence of this personal error has led to the substitution, whenever extreme precision is desired, of a form of photometer in which only one eye is used and in which the conditions of maximum delicacy are more completely met than in any of the earlier types of instrument.

The photometer in question was invented by Lummer and Brodhun. In this photometer as in the instruments of the Ritchie and Bunsen types, the two sources of light to be compared are mounted at the end of a graduated bar or track. Upon this runs the photometer carriage, the essential features of which are as follows:

1. An opaque screen (*O. O*, Fig. 6) upon the whitened faces of which the light from the two sources shines; each face of the screen being illuminated exclusively from one of the sources of light.

2. The device by which both faces of the screen can be observed simultaneously without the use of both eyes. This consists of two precisely similar mirrors *M*, *M'*, mounted facing each other within a dark box not shown in the diagram. The diffusely reflected rays from the screen reach these mirrors at an angle of 45° and are reflected as shown in the figure. Where the reflected rays cross each other at an angle of 90 degrees, is placed an ingenious arrangement technically known as the Lummer-Brodhun *body*, (*BDEF*) which consists of two right-angled reflection prisms placed with oblique faces together so as to form a cube. The face of one of them is, however, cut away so that contact occurs only over a small circular space in the middle of the face. Light from the source *S* (Fig. 6) diffusely reflected from the left-hand face of the screen and received upon the mirror *M*, enters the *body* through the face *AB*. Those portions of the beam which reach the central face of contact pass through uninterrupted, while all other portions are intercepted by total reflection within the prism. Light from *s*, diffusely reflected from the right-hand face of the screen, is reflected by the mirror *M'* to the face *DE* of the *body*. Those portions which fall upon the central area of contact pass through, but the surrounding portions are totally reflected and leave the *body* in paths parallel to and surrounding the path of the transmitted beam which has come through the face of contact from the mirror *M*. Observations are made by means of a small telescope *T*, the field of view of which consists of a disc of light coming from *S*, surrounded by a ring of light from *s*. If the illumination of the side of the screen facing *s* be brighter than that upon the opposite face of the screen, which receives its light from *S*, one sees a bright disc of light surrounded by a dark ring. When the position of the photometer carriage upon which the screen, mirrors, body and telescope are mounted is moved to a position such that the two sides of the screen are equally illuminated, disc and ring are equally bright. The distances from the two sources are then read upon the scale of the photometer bar and the relative intensities of the sources are computed. The accuracy of this form of photometer depends upon the following conditions: (1) The opaque screen must stand in the line joining the two sources of light. (2) Its two faces must be identical in character both as regards color and power or diffuse reflection. (3) The mirrors *M* and *M'* must be identical as regards reflecting power and must be symmetrically placed. (4) The Lummer-Brodhun body must be optically perfect so that transmission through the faces of contact will be complete.

The construction of the instrument is such as to permit reversal by revolving the whole apparatus upon a horizontal axis through 180 degrees. The face of the screen which previously was lighted from the source *S* by means of the mirror *M* and the prism *ABG* now receives its light from *s* and vice versa. Any lack of uniformity in the two sides of the apparatus is thus readily detected and can be eliminated.

Standards of Light.—When, owing to the development of the gas industry, the art of photometry began to take on commercial importance, it became necessary to have recognized standards of comparison. The standard adopted in France was a vegetable oil lamp with mechanical draft burning colza-oil and known from its inventor as the *Carcel lamp*. The dimensions of the lamp were carefully specified together with the form and size of the chimney and the amount of oil (42 grams an hour) to be consumed.

In England the light unit adopted by gas manufacturers and subsequently legalized by the board of trade was the light given by a candle. The British standard candle was made of spermaceti. It was slightly conical in shape for convenience in molding and of such size ($\frac{9}{10}$ inch in diameter at the bottom, 10 inches long and $\frac{8}{10}$ inch in diameter at the top) as to consume 120 grains of wax per hour. The wicks were made of three strands of cotton, each strand consisting of 18 strands.

In Germany the manufacturers of illuminating gas adopted as their standard a candle of paraffin. This candle, which is known as *Vereinskerze* had a diameter of 22 millimeters. The wick consisted of 25 strands of cotton. The height of the flame when burning normally was 50 millimeters. In Munich the legalized standard agreed upon between the city and the gas company was the light from a stearine candle slightly conical in form, of a mean diameter of 20.5 millimeters, the height of the flame being 56 millimeters.

The practical advantage of the candle as a light unit, which consists in the fact that it is a form of light with which the public is familiar, led to the introduction in France of a standard candle known as *la bougie de l'étoile*. This was a stearine candle consuming 10 grams an hour. Its light was approximately equal to $\frac{1}{7}$ of a carcel. The height of the flame was 52.5 millimeters.

Extended studies of the performance of standard candles and countless attempts to determine the relative intensities of the various

forms legalized in the different countries have only served to demonstrate the inadequacy of this source of light even when prepared with the utmost care, to serve as a standard in photometry. Almost the only advantage such a unit possesses is found in the fact that the term *candle-power* has a familiar sound to the public.

The range and character of the fluctuations of the British standard candle may be seen from the curve in Fig. 7 which is taken from measurements made by Sharp and Turnbull ('Transactions of the American Institute of Electrical Engineers,' Vol. 13, pages 145, 1896). The curve covers a period of 60 minutes during which the brightness of the candle was observed at intervals of 30 seconds. It will be seen that the intensity of the flame is subject to frequent fluctuations often amounting to more than 10 per cent.

The altogether unsatisfactory performance of the various forms of standard candle has led to numerous attempts on the part of photometrists to find a more reliable standard of light. A form of standard lamp introduced by Methven (1878) and consisting of an Argand

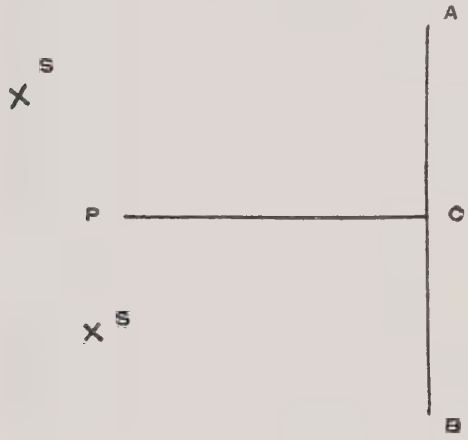

FIG. 1.—Bouguer's Photometer.

burner for ordinary illuminating gas with a metal screen which cuts off all but the central portion of the flame has been extensively used in gas photometry. The tests of this standard have shown, however, that it is subject to variations but little less than those of the candle, owing to the variable character of the gas employed. In 1877 Harcourt introduced a standard lamp in which the petroleum product known as pentane is the fuel employed. This substance which is obtained by fractional distillation cannot be readily obtained in complete purity, but the distillate which boils off at 50° C. consists largely of pentane with a small proportion of other closely allied hydrocarbons. The liquid is highly volatile and in the Harcourt lamp the vapor is ignited at the end of a metal tube extending about two inches above the wick. A modified form of the pentane standard lamp is extensively used in gas photometry in the United States and is said to give excellent results.

If a luminous flame is to be the standard it is essential to find a fuel of known and definite composition and to devise a lamp which will insure its combustion under uniform conditions. Extensive experiments with lamps burning vegetable and animal oils and with a variety of petroleum lamps have only demonstrated the necessity of a proper fuel.

One of the few available fuels of known chemical composition is amyl acetate. A standard lamp in which this liquid is used as the combustible was described by Hefner-Alteneck

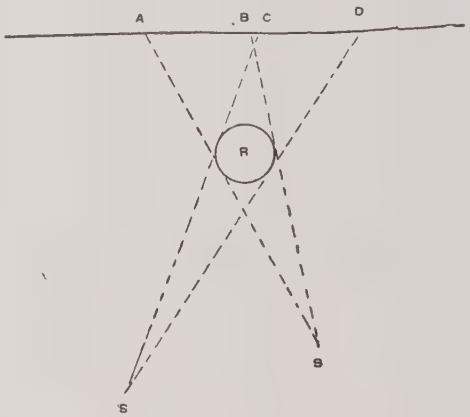

FIG. 2.—The Shadow Photometer.

in 1884 ('Elektrotechnische Zeitschrift,' 1884, page 20). The performance of this lamp was so promising that it was, after thorough and systematic study at the Imperial Physico-Technical Institute in Charlottenburg, reduced to standard form. The modified type of amyl-acetate lamp thus produced has become recognized as the most reliable and desirable form of primary standard thus far proposed.

The Hefner lamp in the final form given it, as the result of the experiments made in Charlottenburg, consists of a cylindrical body of brass upon which is mounted the wick tube. This is a vertical tube of German silver, the height, diameter and thickness of wall of which are accurately specified and the dimensions and details of construction of which must be followed with precision if the intensity of the flame is to agree closely with the standard. Upon the accuracy with which it is possible to follow these specifications, in metal working, the performance of the lamp depends. Lamps which are faithful copies of those upon which the original investigations were carried out give results far more consistent as to intensity of light than have been attained with any other form of standard in which a flame is used, and it is this complete and accurate reproducibility which has caused the Hefner lamp to be adopted as the best available primary standard. The

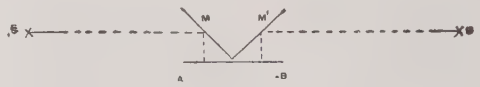

FIG. 3.—The Ritchie Photometer.

light-giving power of the flame of this lamp, like that of all flames, varies not only with the composition of the combustible but likewise with the height of the flame and with the amount of moisture in the surrounding air. The relation between flame-height and intensity as determined by Liebenthal to whom our knowledge of the performance of the Hefner

lamp is chiefly due, is shown in the following table:

Flame heights	Intensities
20 mm.	0 38
25 mm.	0 55
30 mm.	0.70
35 mm.	0.85
40 mm.	1.00
45 mm.	1.12
50 mm.	1.25
60 mm.	1.50

To determine the height of the flame a gauge, which consists of a lens throwing a magnified image of the tip of the flame upon a disc of ground glass, is mounted with its axis 40 millimeters above the top of the wick-tube as shown in Fig. 8. The character of the wick does not affect appreciably the intensity of the flame.

A precise relation between the intensity of the Hefner unit and the various standard candles cannot, owing to the inconstancy of the latter, be said to exist. Since, however, candle-power is still the term according to which nearly all artificial sources of light are rated it has been found necessary to adopt some definite ratio. The photometrists of the Physico-Technical Institute, using numerous data obtained by various observers, found as a mean value, 1 Vereinskerze = 1.2 Hefners; also 1 British Standard Candle = 1.14 Hefners, or 1 Hefner = .877 British Standard Candles. Schiele from extensive measurements found 1 Hefner = .881 British Standard Candle. It is probable that the factor .88 gives as fair a ratio representing the average performance of the candle as can be obtained.

Another substance of definite composition the flame from which would be a very desirable standard of light is acetylene. The advantage of such a flame over that of the amyl-acetate lamp, the ruddy color of which makes comparisons with the brilliant sources of light used in modern illumination uncertain, lies in the fact of its far greater intensity and whiteness. Unfortunately acetylene on account of its richness in carbon will burn without smoking only when mixed, before escaping from the burner, with a considerable amount of air. In all practicable forms of acetylene burners thus far devised the openings for the egress of the gas are very small. It is on this account difficult to produce

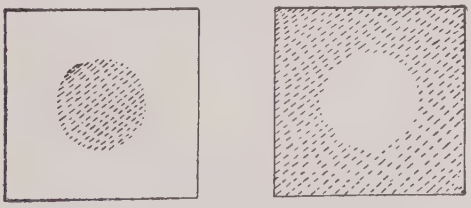

FIG. 4.—The Bunsen Disc.

burners all of which will give precisely the same candle-power. Owing likewise to the minuteness of these apertures the burner is subject to partial choking by small particles of lime, etc., deposited from the gas. Thus the amount of gas flowing under a given pressure is reduced and what is quite as serious, the proportions of the mixture of acetylene and air upon which both the brightness and the color of the flame depend is changed. Because of the difficulty of burning acetylene under completely controllable conditions, there is at the present day no standard burner for use in photometry, but as a secondary standard, subject to repeated comparison with some reliable primary source, the acetylene flame has been found to be of great value.

Incandescent solids maintained at a constant temperature by the action of the electric current would seem to offer possibilities for the construction of a light standard free from the objections to which all standard flames are nec-

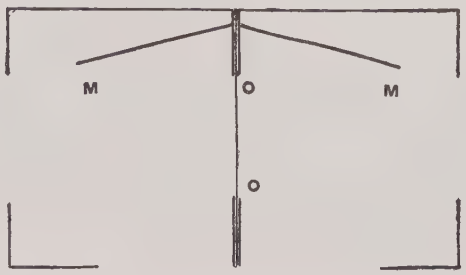

FIG. 5.—Mirrors and screen of Bunsen Photometer.

essarily open. Numerous attempts to produce light standards based upon this principle have been made; the most noticeable being that of Violle. Violle's device consisted of a mass of platinum brought to its melting point by the action of the current. He proposed to define as the standard the light from a square centimeter of the surface of the metal at the temperature of solidification. The advantages of a standard capable of such rigorous definition was so obvious that the electrical congress assembled at Paris in 1881 appointed a committee to determine the question of its practicability. Extended experiments at their hands and on the part of the members of the Imperial-Technical Institute in Charlottenburg have unfortunately led to the conclusion that the platinum standard cannot, with the means ordinarily at command, be made to give constant results.

In the meantime studies of the performance of the ordinary incandescent lamp have shown that we have in it, when properly prepared and handled, a source of light better adapted as a working standard than any other at present available. The carbon filament heated in vacuo by means of a constant current is subject to changes of illumination only as the result of the slow disintegration of the carbon or of gradual loss of vacuum in the bulb surrounding the filament. By the use of storage batteries supplemented by the regulation of a resistance in the circuit it is possible to maintain the filament of an incandescent lamp in a state of incandescence, the constancy of which leaves little to be desired. Given one such lamp, the intensity of which is known or is arbitrarily taken as the unit, it is possible to determine the voltage at which other lamps have the same intensity, so that it is possible to make copies of the original which, whenever subjected to current at the proper voltage, will return to the intensity at which they were when the comparison was made. Thus while it is not possible to construct incandescent lamps which shall at a prescribed voltage give a definite illumination, it is on the other hand possible by comparison of such lamps with a given standard to find the

various voltages at which they will have equal intensities.

The use of the incandescent lamp does not fully solve the problem of the standardizing of light sources; for the determination of the lamp from which the copies are to be made must be by reference to some primary standard such as the Hefner lamp. Having once adjusted one incandescent lamp to agreement with the standard, however, one may make copies of these which will agree with one another much more closely than any two Hefner lamps or than a single Hefner lamp upon successive trials will agree with itself. If one were to start anew, with the Hefner lamp as a standard, and make another set of standardized incandescent lamps, these, though highly uniform, might show no better agreement with the former set than that which one can obtain in subsequent trials with the lamp itself. Such variations of the Hefner lamp amount to about 2 per cent.

The province of the art of photometry does not end with the determination of the intensity

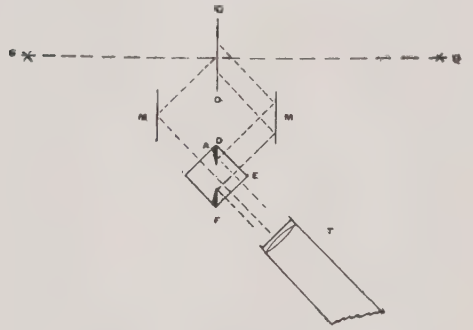

FIG. 6.—Diagram of the Lummer-Brodhun Photometer.

of the light sent out in a given direction from any source. One of its chief purposes is to enable us to deal definitely and intelligently with the problems of illumination and these are complicated by the fact that, in general, sources of light do not radiate with equal intensity in all directions. The accepted unit of illumination among photometricians on the continent of Europe is the *lux*, which is the illumination received from a source of unit intensity at a distance of one metre. The unit source in this definition is the Hefner lamp already described, so placed that the light is received from it in the horizontal plane. The term *bougie-metre* is also used in speaking of this unit of illumination. The term *bougie* (or candle) in this definition is not any of the standard candles already described but a hypothetical candle equal to the Hefner. In countries where British measures are still in vogue a unit of illumination frequently employed is the *candle-foot* which is the illumination afforded by a British standard candle placed at a distance of one foot from the illuminated surface.

The distribution of light from the various sources used in artificial lighting is far from uniform and it is necessary, therefore, in order to give a complete description of the lighting power of any source, to determine the intensity of the source as viewed from all possible directions. In the case of certain sources of light such as the incandescent electric lamp this is easily accomplished by mounting the lamp at the end of the photometer bar in a holder so constructed as to permit of rotation about both a vertical and a horizontal axis without displacing the centre of the lamp from its position. In the case of other sources, such as the arc lamp and most flames, which cannot be

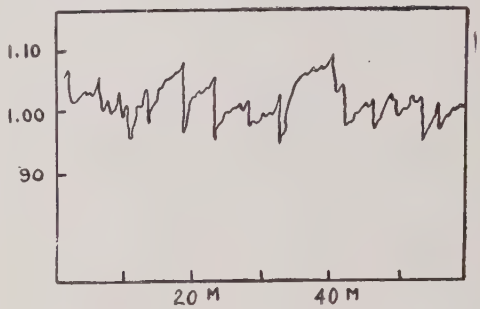

FIG. 7.—Fluctuations of a British Candle.

tipped from the vertical without modifying the distribution of light or interfering with the performance of the lamp, it is necessary to have recourse to a mirror, placed in the axis of the photometer bar, by means of which light can be reflected along the bar. By varying the angle of the mirror the light can thus be viewed from any desired direction. Corrections must of course be made for loss of light at the surface of the mirror.

The results of the exploration of the field of light around a given source are usually expressed by means of curves. The curve showing the distribution in a horizontal plane is called the curve of horizontal intensities. The corresponding curve for any vertical plane is a curve of vertical intensities. In Fig. 9 are given two typical curves of vertical intensities from measurements of an open-arc lamp without shade. Fig. 10 is a diagram showing the illumination of

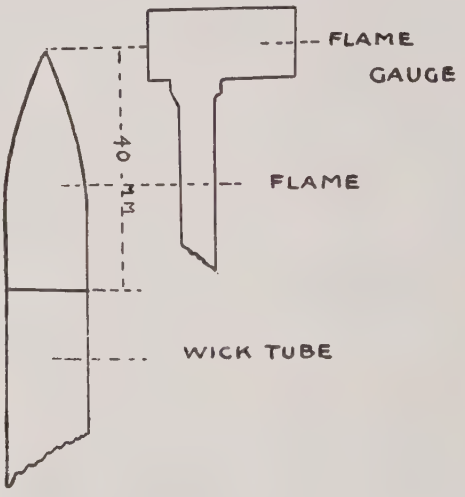

FIG. 8.—Wick tube, flame and gauge of the Hefner Lamp.

the ground at different angles when such a lamp is used in street lighting. When the curve of horizontal intensities is a circle, a single curve of vertical intensities suffices to completely describe the performance of the source of light; when, however, as is usually the case, the curve

of horizontal intensities is not a circle, the curve of vertical intensities will vary in form as the vertical plane to which the curve applies is revolved about a vertical axis through the centre of the source of light. The average intensity of a source of light viewed in the horizontal plane is called the *mean horizontal intensity*. The average intensity, taking into consideration every possible point of view, is called the *mean spherical intensity* of the source.

The rigorous determination of either of these quantities in the case of unsymmetrical sources would take an infinite number of readings. In the case of the incandescent lamp, which will permit of such treatment, it is, however, possible to obtain the mean horizontal intensity by rotating the lamp upon its vertical axis at the end of the photometer bar. Measurements made upon the lamp revolving thus at a speed of several revolutions per second are found to agree well with the mean horizontal intensity as determined by plotting a series of readings taken from different positions at a horizontal plane with the lamp at rest, and integrating the curve thus obtained. The approximate determination of mean spherical intensities of non-symmetrical sources such as the arc lamp, when made with the ordinary photometer and mirror, involves the taking of many individual readings. In the Franklin Institute tests, made at the Electrical Exhibition in Philadelphia in 1885, 65 measurements were made in each determination and these were combined in computing the main spherical intensity. These readings were made from 38 directions distributed as evenly as possible around a sphere of which the light was the centre. To avoid this laborious process numerous special forms of photometer have been devised of which the most successful is that invented by Matthews and used in the extensive studies of the arc light recently carried on under the auspices of the National Electric Light Association. In this instrument which is known as Matthews' *integrating photometer* 24 large mirrors are arranged around the source, the mean spherical

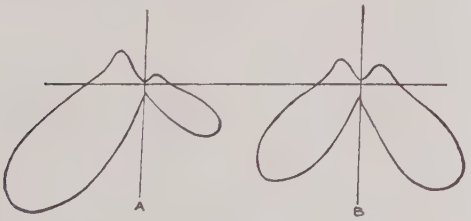

FIG. 9.—Curves of vertical intensities (open-arc lamp).

intensity of which is to be determined, in such a way as to produce upon the photometer screen an illumination proportional to the mean spherical intensity. The adjustment of these mirrors is such as to direct simultaneously toward the photometer the beams of light which the eye of an observer would receive if he were to view the source successively at angular intervals of 15 degrees in a vertical plane. The intensity of the light received in these various directions must further be reduced in the ratio of the sine of the angle between the direction of view and the vertical, and this is done by the interposition of glasses which are smoked until they transmit the desired proportion of the light falling upon them. With this instrument the photometer gives by a single reading a value proportional to the mean spherical intensity of the source.

PHOTOMICROGRAPH. A photomicrograph is a photograph of a microscopically small object. The term microphotograph is sometimes used, but is very inaccurate, and should be used only to designate a very small photograph; e.g., a photograph an eighth of an inch square of the Niagara Falls is a microphotograph. Simple photomicrographs may be made without any expensive special apparatus. A microscope and any camera with a ground glass for focusing will suffice. The lens, or lenses, but not the shutter, are removed from the camera; the eyepiece is removed from the microscope, which is placed in a horizontal position. The eyepiece end of the microscope tube is now inserted a little into the lens barrel of the camera and a black cloth is wound around the place where they come together in order to exclude the light. The tube of the microscope should be exactly perpendicular to the ground glass of the camera. Any strong light may be used, as direct sunlight, a gas mantle lamp, an acetylene lamp, a kerosene lamp, or an electric arc; but ordinary incandescent bulbs are not satisfactory. Remove the mirror of the microscope, since it will not be needed in any photomicrographic work, and let the light come directly into the optical axis of the microscope. If the illumination of the ground glass is uneven and shows a "flare spot," look at the inside of the tube of the microscope. Probably it was not blackened. Put a black paper inside the tube. Modern microscopes are well blackened inside. Move the light back and forth and

sidewise until the best illumination is secured. About six inches from the stage is likely to be a good position.

Suppose we are to photograph a transverse section of a vascular bundle, using a two-third-inch (16-millimeter) objective. With such a low power lens and with all lenses of longer focus, the condenser in the microscope is not only unnecessary but it interferes with good work. Remove it. However, the condenser should be used with objective of one-third inch (eight millimeters) focus and with all objectives of shorter focus. Carefully focus the object upon the ground glass. The ground side of the glass should be next to the microscope. After a sharp focus has been obtained, close the shutter of the camera and insert a plate, just as in ordinary photography. The time of exposure will depend upon the intensity of the light, the speed of the plate and the magnification. Small negatives may be made from lantern slide plates, especially when a contrasty negative is desired. With a gas mantle lamp, a lantern slide plate and a 16-millimeter objective used without an ocular or condenser, try an exposure of 30 seconds. Until one becomes proficient in estimating exposures, it is a good plan to expose 10 seconds; then close the shutter and push in the slide of the plate holder just an inch; then expose 10 seconds, close the shutter and push in the slide another inch; then repeat twice more and you will have exposures of 10, 20, 30 and 40 seconds on one plate. It is easy to determine which is the best exposure and only one plate is sacrificed. A print on printing-out paper from such a negative is very instructive, since it shows the comparative merits of negatives of various densities. A filter, such as is used in out-of-door photography, is likely to improve the negative. Experts use filters of various colors, according to objects and the features which are to be emphasized. The developing is the same as in case of lantern slides (q.v.), or as in case of ordinary photography, if a fast or medium plate is used. With higher powers, use the condenser and, if necessary, the ocular. If much work is to be done, the need for a solid support for both camera and microscope will be realized. A simple contrivance which any one can make for himself is illustrated in Fig. 1.

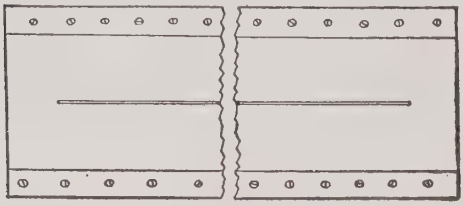

Fig. 1.

Use a clear board an inch thick, a foot wide and five feet long. On top of the board, at the sides, screw two strips, an inch thick, one and one-half inches wide and five feet long, so as to form a guideway for the camera. A long slit, one-quarter inch wide, should be made to accommodate the screw which is ordinarily used to fasten the camera to a tripod. If the same camera is to be used for all work, the space between the two long strips should be just wide enough to admit the camera. A strip of wood one-half inch thick, an inch wide and five inches long, placed over the horse-shoe base of the microscope and held in place by a bolt put through the long slit, will hold the microscope in position.

For the finest class of work, especially where very high magnifications are desired, elaborate and expensive apparatus is very convenient. In these elaborate forms, experts do not always use the same arrangement. The relative positions of the various parts, as shown in Fig. 2, is very effective.

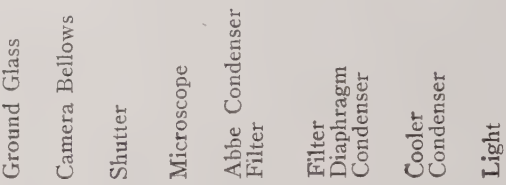

Fig. 2.—Relative positions of the various points.

Charles J. Chamberlain.

PHOTOMURALS. As the word suggests, photomurals are photographs applied as murals, and where used, constitute the only or the dominant decoration. Generally they are mounted directly upon the surface with such intermediate backing as may be necessary or they may be attached to panels, which, in turn, are fixed to a wall either permanently or in a manner permitting easy removal.

There is no prescribed size at which a photograph reaches proportions justifying its designation as a photomural although enlargement of the original is almost always implied. Magnification of 30 times the original size is a common average. In some photomurals, the objects appear hundreds of times larger than they are portrayed in the picture or negative from which the mural was made. So far as the photographic processes involved are concerned, there is no limit to the photomural's size.

It is erroneous to conclude, however, that relatively large proportions are an inevitable characteristic of the photomural. As indicated above, the manner of application to the wall surface and the mural's function as the sole or dominant decorative element are essential factors. A further vital consideration and one receiving increased emphasis is the degree to which the photomural conforms to the authentic principles long associated with mural art in general.

The photomural is a natural growth of the enlargement process, a development that occurred many years ago in photography. It has become practical largely through improvements in emulsions and other factors which almost entirely eliminate «grain» in the finished enlargement.

Experiments with photomurals had been made previously but the first successful installations for actual use were introduced about 1925. One of the first was mounted in a Chicago home. The subject is the famous Taj Mahal and the photomural was made from a small camera snapshot. The mural was hung

An excellent example of the use of a photomural in a private residence. (Home of Earl Coryell, Lincoln, Nebraska.)

in 1927. Although preparation of photomurals much larger than this one is a common occurrence today, enlarging a camera picture of but a few square inches in size to the proportions required for the alcove in the Chicago residence involved various problems which at the time were attacked with grave misgivings. This particular photomural is still in good condition and the success which crowned this early effort was one of the chief incentives to further experiments and developments.

The photomural saw its first large scale adoption and usage at the Century of Progress Exposition in Chicago in 1933 and 1934. Hundreds of them were installed. Heavy demands were made for photomurals at subsequent fairs. At the New York World's Fair of 1939 more than 500,000 square feet of photomurals were installed. Many installations were made for San Francisco's Golden Gate Exposition of the same year.

Since the first production, photomurals have been prepared for a wide variety of interiors and for locations in many parts of the world. They are frequently used in offices, public buildings, homes, clubs, trade expositions, churches, schools, window displays, dining rooms and restaurants. Architects and industrial designers have contributed much to their development and in some instances rooms and other interiors have been planned with a photomural installation in view.

One of the most famous photomurals known is in the Ford Motor Company's rotunda at Dearborn, Mich. It is nearly 600 feet long and 20 feet high and in effect is the equivalent of a single photograph, showing scenes during the manufacture of a motor car.

From the preparation of the original photograph to the final details, the making and installation of a photomural involves a number of special and exacting steps. One of the most spectacular is the projection process. This is done by means of a special projection camera which throws an enlargement of the image from the negative upon a large sheet of sensitized paper. Control of the lighting used, accurate exposure and developing time and careful measurements are a few of the particulars required. Special photomural paper generally is employed. It comes in widths of 20 to 50 inches and in large rolls sometimes containing 1,000 feet or more.

The photomural sections or individual prints being much larger than ordinary prints usually require special washing and developing tanks. In one large photographic plant, an especially effective washing tank has been made from stainless steel. It can handle several prints up to 25 feet long at one time. A special system of circulating the water to insure a thorough cleansing has been developed. The stainless steel is an added safeguard against the injurious chemical action during the washing.

Checking the prints to see that the «hypo» has been removed, absolute chemical purity of all materials used, carefully regulated temperatures, special adhesives, muslins for wall coverings and lacquers which will cause no discoloration or harmful chemical action upon the photomural are other details necessary to insure a successful installation. Since most photomurals are made up of two or more sections carefully mounted to give the appearance of a single print, great pains must be taken in the exposure to obtain uniformity of tone and in the hanging to allow for paper stretch, concealment of joints and exact register of one section with reference to its adjoining sheet.

A wide variety of tones and finishes is employed in photomural work. Hand coloring in tones closely approximating those of nature is frequently done pending the development of natural color photography to a point where it will be practical for use in photomurals.

Until now, the photomural has been received largely as a mere «blowup» of an original photograph. With the improvements being made in the technique of production process, there is a growing tendency to bring the photomural to a higher degree of artistic excellence.

Mechanically, and technically, the photomural has «arrived» and has found a useful place for itself. Æsthetically it is probably only at the beginning of its development. While the camera cannot expect to replace the brush and easel, it can achieve much higher standards of artistic value than it has yet accomplished in photomurals.

CHARLES D. KAUFMANN,
President, Kaufmann and Fabry Company.

PHOTOPHONE, the name given an apparatus for transmitting articulate speech to a distance along a beam of light. It was first described in 1880 by Alexander Graham Bell, known in connection with the telephone, at the Boston meeting of the American Association; but already in 1878 its inventor had announced the possibility of «hearing a shadow» by means of a similar agency. It has never been commercially introduced. The success of the photophone depends on the peculiarities of the metal selenium. Crystalline selenium offers a high degree of resistance to the passage of an electric current; it is eminently sensitive to light; and the resistance is less when exposed to light than in the dark, being in some cases only a 15th in the light of what it is in the dark. Professor Bell, his friends and assistants devised some 50 forms of apparatus, for so varying the transmission of light to prepared selenium as to produce audible sound. In the photophone found most serviceable the transmitter is a plane mirror of silvered microscope glass or thin mica; the receiver, fixed at a distance without any connection, is a parabolic reflecting mirror, in the focus of which is placed a sensitive selenium «cell,» connected in local circuit with a battery and telephone. When the apparatus is used, a strong beam of light is concentrated by a lens in the plane mirror; the speaker directs his voice against the back of this mirror, which is thrown into vibrations corresponding with those of the voice. The reflected beam of light, to which corresponding vibrations are also communicated, is directed through a lens to the receiving mirror, and creates in the selenium cell a rapidly variable current, which at the end of the telephone attached becomes audible again as vocal sound. When first described, the photophone had been used effectively with a distance of 230 yards between transmitter and receiver. The rays of the oxyhydrogen light, or of an ordinary kerosene lamp, suffice for transmitting articulate speech. The loudest sounds obtained from the photophone were produced by means of a perforated disc, noiselessly revolving so as rapidly to interrupt the light in transmission.

It was also found that a very audible sound could be procured from the selenium without the aid of telephone and battery. A beam of intermittent light will produce a strong musical note from the selenium. Further experiment showed that selenium is not the only substance thus sensitive to light. Still louder sounds than these obtained from the selenium directly, though not articulate, were got from diaphragms of hard india-rubber and of antimony; and sounds of varying intensity were given out by many other substances, including gold, silver, platinum, copper, zinc, lead, paper, parchment and wood. Consult Fournier d'Albe, E. E., 'The Moon-Element' (London 1924).

PHOTOPLAY, the technical name given to a moving-picture which presents a complete drama. The conditions under which a moving-picture is made and exhibited place the photoplay in a distinct class. It can, like the novel, short story, or the regular theatrical play depend upon language to explain situations or to express thoughts and emotions. The photoplay differs from other moving-pictures in that it has a definite plot, which is worked out by a series of dramatic scenes. There is no limit to the number of these separate scenes; they may run up to 40 or 50, if necessary to round out the story. Nor are there any bounds within which the plot action shall move forward. The ability to join into one picture films made at the opposite ends of the earth, if desired, give the widest latitude to the inventive faculties of the author. In these peculiarities the photoplay leans more toward the plan of the novel than to the theatre play presented in three or four acts, and within the confines of the stage. The scenes in which the photoplay is presented are not required to progress consecutively as to time of happening: it is entirely permissible for the action to «cut back» as in the novel, to take up a parallel sequence of events needed to bring the action to a climax.

The production of a photoplay requires the perfect collaboration of several highly skilled specialists. The author devises his plot and to a large degree the scenes which shall express it. His manuscript is submitted to the photoplay editor, who passes on the availability of the story for photoplay presentation. He may reject it altogether, return it to the writer with suggestions for amendment, or, if the subject appeals to him as worthy, may make the emendations himself. In the larger establishments the editor has a corps of readers to assist him in winnowing the great mass of manuscripts submitted by would-be photoplaywrights. For every manuscript accepted more than 700 are rejected as unsuitable. The accepted photoplay goes to the director of the establishment. His is perhaps the most vital part of all, as it is his task to make real what the author and editor have imagined. He decides upon the make-up of the scenes, what scenery is to be used, or perhaps made especially, what setting, the actors who are to take part, the clothes they are to wear, their appearances and positions on the stage, and conduct of rehearsals, and the ultimate direction of the actual production of the play before the camera. The camera man's work is largely mechanical but calls for extreme accuracy. Some of the scenes may prove to be inadequate, and may have to be done over again—or possibly omitted altogether. Perhaps the whole play will be rejected as not up to the standard of the firm which must stand sponsor for it in the film market. The editor and director then decide as to the inserts actually needed to give the utmost finish to the play, and these are made by the photographic staff, put into their proper places in the negative, and the whole cemented into one continuous strip. When this is finally satisfactory, many copies are made and distributed by the business department of the producing company to the exhibiting houses all over the country and in foreign lands as well. So that no one locality may have an advantage over another in point of time on any given picture-play, it is customary for the manufacturer to place a «release date» on the film, before which time it may not be shown.

The development of the «Movietone,» or «Talking Picture,» now makes possible the production, as photoplays, of legitimate stage plays with remarkable fidelity to the original. See also Moving Pictures, for description of the instruments and processes used in making and exhibiting the films.

PHOTO-SCULPTURE, a novel process used by sculptors for producing statuettes by the aid of photography. It was invented by M. Villème, a French sculptor. The model stands in a studio of special construction, in the centre of a circle of 24 cameras, by all of which he is photographed at the same moment. The 24 negatives are then projected in succession on a screen by means of an optical lantern and the artist goes over the outline of each with the tracer of a pantograph, a cutting tool acting upon a lump of modeling clay, mounted upon a turn-table, being substituted for the usual pencil. After each photograph is gone over, the clay in turned through 15°, and after a complete revolution it is removed and finished by hand.

PHOTOSPHERE, *in astronomy,* the luminous envelope, supposed to consist of incandescent matter, surrounding the sun. See Sun.

PHOTOSTAT, an adaptation of the camera through the addition of convenient mechanism to the making of photographic copies on paper, of documents, printed matter, engravings, etc. The hood of the lens is fitted with a 45-degree prism by which rays of light from below are turned horizontally into the level camera.

A second prism within the camera so directs the rays that the usual crisscrossing of left to right and *vice versa* is corrected and the face of the negative reflects the arrangement seen by the operator as he stands at the camera. The negative is made on paper coated with a slow but rich emulsion. The object of which photostatic copies are to be made is clamped upon a shelf-like support extending horizontally, which is movable vertically along a scale which indicates the proportion of the copy, as to larger or smaller. Positives are made in the camera by placing the negative on the «shelf,» a separate exposure being made for each positive. Developing of the image is as usual in the dark room. The lighting of the object is done with Cooper-Hewitt mercury vapor lamps, one on each side.

PHOTOSYNTHESIS, the building up of chemical compounds through, or with the aid of, the action of light, resulting in the formation of new substances that are higher in type than the materials from which they are formed, as evidenced by a more complex structure, or the possession of a greater degree of energy. The most widespread example of photosynthesis is that of the production of sugar, and the transformation of this into starch, from carbon dioxide and water in the green leaves of plants. In order to produce chemical action the light must apparently excite some special resonant mechanism in the molecule, and certain additional conditions at present unknown must doubtless be fulfilled also in connection with the chemical potentials of the absorbing substance and the other substances that might conceivably be produced from it. Light is an exceedingly rapid periodic disturbance of the ether that fills space and penetrates between the ultimate particles of which matter is composed; and when a substance undergoes chemical modification in consequence of being subjected to the action of light, it is probable that some part of the molecular mechanism of the substance has a vibration period equal to that of the light that produces the change. When bodies or systems that are large enough to be dealt with individually and which are capable of vibrating or oscillating in certain definite periods are subjected to a disturbance of external origin having this same periodicity, we know that their motions may undergo marked and important changes, and we can hardly doubt that the same thing is true of the molecular systems. A homely illustration of the absorption of vibratory energy in this way may be had by singing a loud note into a piano. Certain of the strings of the instrument — namely, those that are capable of vibrating with the same frequency as the air waves constituting the tone that is sung — are set in motion, and if the singing is abruptly stopped these particular strings give out a faint sound of the same pitch, thereby proving that they have absorbed vibratory energy from the air. When light penetrates a substance that is capable of having photochemical changes induced in it, energy is absorbed by the molecules or atoms of the substance in a presumably similar way, and it is this absorbed energy that brings about the change. This much appears fairly evident, though we do not know the precise mechanism by which the result is accomplished. In some cases in which an effect of this kind occurs the molecules may be merely shaken apart, with the consequent formation of new compounds of a simpler nature; and when this occurs the disruption may be attended by the liberation of energy, so that the final products contain less energy, on the whole, than the parent substance from which they were produced. Other compounds, more stably constituted or more efficiently absorptive, may be able to store up the vibratory energy of the light until they become capable of entering into combinations of a higher type, and in a case of this kind we should have a true photosynthesis.

Inasmuch as light must be absorbed in order to give rise to photochemical action, we find that such action is characterized by high absorption power on the part of the substance that undergoes the chemical transformation. If all the incident light were absorbed the substance would reflect nothing and would, therefore, appear black. If the absorption were only partial and if it took place in such a way that the absorbed energy constituted the same fraction of the incident white light at every wave-length, then the reflected light would contain all the colors that exist in sunlight and in the same proportion in which these colors must be present to produce the sensation of whiteness; and hence in this case the substance would appear white or gray. In the actual case as we find it in nature, the incident light is only partially absorbed, but the absorption is quite marked (and may even be almost complete) between certain wave-lengths, while in other parts of the spectrum there is little or no absorption. The absorbing substance, therefore, appears colored, since it absorbs certain wave-lengths with marked efficiency and gives off the others by reflection. In studying the absorption of light scientifically the spectroscope is employed, and the particular wave-lengths that are absorbed are determined by allowing the spectrum to fall upon a uniformly thick layer of the substance under investigation and examining the transmitted light to see what particular colors have been absorbed — absorption being indicated by the presence of dark bands (or "absorption bands") in the spectrum of the light that has passed through the test layer. In the case of the green coloring matter of plant leaves, the absorption band that corresponds to the photosynthetic activity is in the red part of the spectrum.

It is not possible to determine with precision the efficiency with which the absorbed vibratory energy of the light is converted into potential chemical energy in the leaf of a growing plant, but it is known that this efficiency is quite high. According to the best available estimates it may range from 40 per cent upward, and some authorities have even estimated it at 98 per cent in special cases.

The synthesis of highly organized compounds from carbon dioxide and water is performed by living organisms in various ways. Certain of the bacteria, for example, perform syntheses of this kind by utilizing the energy obtained by the simultaneous oxidation of hydrogen or other substances that may be present. Most of the plant life of the world, however, depends upon photosynthesis, effected through the agency of the green "chlorophyll" that the leaves contain. The coloring matter extracted from green leaves contains four recognizably distinct constituents — two of which are green

and two yellow. The green substances appear to be the ones that effect the photosynthesis. One of them (chlorophyll A) is bluish green in color and the other (chlorophyll B) is yellowish-green, and appears to be an oxide of chlorophyll A. These constituents are probably identical in all plants, and they contain magnesium and nitrogen, but no phosphorus or iron. The yellow pigments that are present in the leaves are carotin ($C_{40}H_{56}$) and its oxide xanthophyll ($C_{40}H_{56}O_2$). Carotin is identical with the "lutein" that occurs in the corpora lutea of mammals, and xanthophyll is isomeric with the "lutein" of fowl's eggs. The view that xanthophyll is related to cholesterol is now known to be erroneous. Carotin may perhaps assist in the decomposition of carbon dioxide.

There is a close and suggestive structural similarity between chlorophyll and the hæmoglobin of the human blood, and this fact may lead to a further understanding of the way in which chlorophyll acts. We do not yet know how it affects the synthesis of starch and sugar from carbon dioxide and water. In the living leaf the chlorophyll occurs in the form of concentrated layers upon (or near) the surfaces of certain tiny structural granules called "chloroplasts," which appear to perform an important function of some kind or other. It has been shown, for example, that when a seedling is grown in the dark and subsequently placed in the light it does not necessarily possess photosynthetic power as soon as chlorophyll appears in it; and this shows that other elements, structural or chemical, are needed before photosynthesis can occur. It is also interesting to note that a mere trace of chloroform vapor in the air stops photosynthetic activity, even in a healthy and vigorous leaf.

The suggestion that formaldehyde is formed in the leaf at first, according to the formula $CO_2 + H_2O = CH_2O + O_2$, which was entertained by experimental botanists for a time, was finally set at naught by the discovery that it was merely an addition product in the development of chlorophyll B from chlorophyll A, the combination of chlorophyll A with carbon dioxide forming chlorophyll B *plus* formaldehyde. The chlorophyll B then reacts with carotin and water to form chlorophyll A and xanthophyll, which, in turn, through the action of some unrecognized enzyme, is re-formed into carotin, with the release of oxygen, after which the formaldehyde product is polymerized to form a hexose sugar. This, at least, is the conclusion of the eminent experimenter, E. Baly, and has the merit of accounting scientifically for the presence of all the materials found associated with chlorophyll in the leaf.

Another result of Baly's work, borne out by the experiments of Willstätter, is the conclusion that chlorophyll is a light-energized catalyst, and not merely a screen, or a transformer of the wave-lengths of light. As a catalyst it takes an active part in the production of the carbohydrates formed. Thus, its chief rôle is chemical, and its service as a color screen, which action it certainly performs, appears to be incidental.

C., 'The Physiology of Photosynthesis' (London 1924); Spoehr, H. A., 'Photosynthesis' (New York 1926).

ALLAN D. RISTEEN.

PHOTOTHERAPY, the treatment of disease by light — sunlight and electric light (For treatment by the Roentgen ray or X-ray, see RADIUM THERAPY.

From the very earliest times sunlight has been considered an important aid in the preservation of health. The ancient Greeks and Romans exposed their naked bodies to the sun in the open air to recruit mental and physical energies, and built balconies or terraces (*solaria*) on the roofs or southern walls of their dwellings, so that the occupants could sun themselves. Exposure to the sun's rays was also adopted by the physicians of those times as a remedy for many affections, "especially dropsy, inflammation of the kidneys, and paralysis." Celsus, the Latin writer, recommended for those with weak digestion a house "well lighted, having the winter sun"; but while he and Galen advocated sunlight as a remedial agent they pointed out the evils resulting from excessive insolation. Much has been written within the last century on the remedial value of sunlight. In 1815 Cauvin presented a thesis "on the benefits of insolation"; prior to 1820 Ebernier, Girard and others discussed the effects of sunlight on animal life; and in 1847 Richter, at Göttingen, wrote on "insolation, or the power of the sun on the human body." In 1848 Perreira spoke of solar light as a "vivifying and vital stimulus," adding: "In maladies characterized by imperfect nutrition and sanguinification, as scrofula, rickets and anæmia, and in weakly subjects with œdematous limbs, free exposure to solar light is sometimes attended with the happiest results."

The importance of light for healthy growth and development has been recognized by sanitarians for many years. Solaria or sun-rooms are a part of some modern hospitals. Houses and rooms receiving little or no sunlight are unhealthful. In a military barrack at Saint Petersburg the mortality was three times greater on the dark than on the light side of the building. Animals and plants living in the dark become bleached, as is celery. Clinical observations show that a want of sunlight produces depression of spirit, lack of energy, loss of appetite, disturbance of digestion, turbid urine and a kind of homesickness. The face becomes pale (etiolation), the blood is thin, the red corpuscles are diminished, pulse is frequent and weak, palpitations of the heart occur on the slightest exertion, there is muscular debility, little recuperative power, and an increased susceptibility to contagious diseases.

Interesting experiments and observations have been made as to light, by Becklard, Becquerel, Draper, Edwards, Gardner, Hunt, Landgrebe, Hammond and others; but, as one of the writers observes, "we do not know what is the exact effect produced by light. Does it," he inquires, "act directly, or is its only effect to modify the intensity of certain functions, such as respiration?" Later Edward Smith proved that light is a powerful stimulus to respiration, that "under the influence of daylight one-third more atmospheric air enters the

lungs than under darkness or even under exposure to artificial light." Hence the vigor of the "ruddy, healthy peasant who retires to rest with his cattle and is up with the lark" is believed to be mainly due to the thorough oxygenation and subsequent reddening of the blood by much contact with oxygen in the light and air of the day. Where direct sunlight cannot be obtained in rooms, reflected sunlight by means of mirrors has been found serviceable, in the maintenance of health. A room with a southern exposure is desirable. Sternberg and others have shown that bright sunlight, independently of the heat of the sun, is germicidal, destroying various pathogenic organisms, sometimes within a single hour. Sunlight is thus an important disinfectant. The sterilizing influence of light in the purification of water and sewage has been repeatedly proved (see STERILIZATION). But the fact that the germicidal property of light chiefly depends on its blue and violet rays was proved by Finsen near the close of the 19th century. It has been recently stated that the strongest sunlight has too feeble bactericidal properties for therapeutic purposes; for example, it does not kill bacterial skin-disease in the summer; but a concentrated focused light, transmitting as many blue, violet and ultra-violet rays as possible, such as the concentrated electric light of Finsen, is necessary. This light kills bacteria in a few seconds when spread on a thin film of agar. But Angell in 1878 had reported cases of acne speedily cured "by exposure to direct and entire sunlight."

Light has long been considered a complex agent. It has been known that the sunbeam is resolvable into rays of various colors (violet, indigo, blue, yellow, green, orange, red), which embody luminosity, heat and actinism, the chemical property of light. It was known that the red rays of the spectroscope were heat-rays; that the rays toward the violet side were actinic or chemical; that luminosity was strongest in the orange and yellow rays. Later it was discovered that there are invisible heat-rays beyond the red, and actinic rays beyond the violet, and these were called ultra-violet. About 1845 Gardner and R. Hunt experimented with the rays separated by a prism, and ascertained some interesting facts as to the effects of blue, yellow and violet rays upon vegetation. Ponza, an Italian physician, found blue and violet light to be soothing to the insane. Gen. Alfred Pleasanton, in his advocacy of blue light as an invigorator, claimed too much for it, and the «blue-glass» craze died out. Most physicians believed that treatment by isolated rays of light did not possess "very essential therapeutic value." A few clung to the idea that if the excess of heat and light could be eliminated the actinic rays might be of value.

It was reserved for Niles R. Finsen, a physician of Copenhagen, in 1895, to utilize scientifically the constituent or spectroscopic elements of light as therapeutic agents. In 1832 Pictou of New Orleans published a pamphlet proving that the absence of light would prevent suppuration and pitting (scarring) in smallpox, and recommended that the eruption should be protected from air and light. Finsen, by numerous experiments on worms and insects, convinced himself that under red light they were comfortable, and under blue light were irritated. Then reading Pictou's pamphlet, he inferred and advised that keeping smallpox patients in a red light would be as efficacious as darkness in preventing pock-marks by excluding the irritating actinic rays. If the skin is protected against the chemical rays inflammation will diminish and suppuration be prevented. In August 1893 Svendson in Norway and in November 1893 Benckert in Sweden used the red-light treatment with smallpox patients, and found that suppuration was abolished, scars were rare and insignificant and the disease was shortened. Even a very little daylight admitted to the room did harm, so sensitive was the inflamed skin to the actinic rays. In mild cases a clear red light was found sufficient; in severe cases a deep red light was necessary. Having proved that red light was inimical to the germs of smallpox and other eruptive diseases, Finsen turned his attention to the effect of decomposed light on other germ-diseases, especially lupus. He proved (1) that the bactericidal action of light is practically limited to the blue, violet and ultra-violet rays, and is greatly intensified by concentrating the rays by means of a suitable apparatus; (2) that the actinic rays so concentrated will penetrate the skin to a small degree and will go deeper if the red blood be pressed out of it — hence they would be of value in superficial cancer, baldness of microbic origin, acne, etc.; (3) that they have power to produce inflammation of the skin (*erythema solare*). Finsen's first case of lupus was successfully treated in 1895, with an ordinary arc electric light and a hand-lens, the red and ultra-red rays being filtered out through blue water. He then devised and used a sun-apparatus consisting of two lenses of glass, one plain, the other convex, framed in a brass ring, mounted on a stand, and which admitted of adjustment and focusing. Between the lenses was a bright blue weak ammoniacal solution of copper sulphate. Discovering that the ultra-violet rays were more efficacious than the violet in killing bacteria, he abolished the blue-water filter which prevented the ultra-violet rays from passing, and used clear distilled water, which sufficiently absorbs the red and ultra-red burning rays. Lenses of clear quartz-crystal were substituted for those of glass, it being found that they are better heat-filters and allow the chemical rays to pass almost unimpaired. As sunlight could not be depended upon for regular and systematic treatment, Finsen turned to the electric light.

The Finsen apparatus as now constructed consists of an arc-lamp, of from 40 to 80 amperes and one or more telescopic tubes of brass for concentration and focusing. Each tube closed is three feet four inches long and can be extended 10 inches. The head-piece of the tube has two plano-convex lenses of quartz-crystal, one with the convexity toward the light, the other with the plane surface in contact with the plane surface of the first lens. Toward the lower end of the tube there is a chamber for distilled water, designed to diminish the heat-rays not eliminated by the crystal lenses. The light-rays, emerging from this bath, are concentrated by another quartz-crystal plano-convex lens at the distal end of the tube upon the surface to be treated, the convex surface of the lens being toward the patient. To enable the rays to penetrate the surface more deeply by squeezing out the blood a compressor may be

used, consisting of two quartz-crystal lenses, one plane, the other convex, with a chamber between having an inlet and outlet, through which water can be kept continuously flowing still further to cool the rays. This compressor is either held in place by an attendant or tied on. An improvement by Hopkins of Brooklyn admits of the adjustment of the tube on a stand to suit the case to be treated, as in uterine carcinoma.

The objection to the Finsen apparatus are the cost, the usually frequent and tedious treatment necessary — one hour a day for months — and the effects sometimes produced on the eyes. It has mainly been used in cases of *lupus vulgaris,* and *lupus erythematosa,* birth-marks, acne, and rodent ulcer. Dr. Rollier of Switzerland has had great success in employing the sun's rays for the open air treatment of tuberculous joint affections in children.

Though Finsen's discovery may not do all that has been claimed for it, it marks a great advance, especially in the cure of lupus. Out of 456 cases treated by Finsen, 130 were cured; the disorder had not recurred in from one to five years. Cases of abdominal malignant cancer have been successfully treated in this country. It is claimed by originators of improved apparatus that as much can be done therewith for lupus in 20 minutes as Finsen effected in an hour or more, that only 30 amperes, instead of 80 are necessary and that one application in several days is sufficient.

The Minim light, suggested by Minim of Saint Petersburg, which is an ordinary incandescent light, covered by a bulb of natural blue glass, with a reflector, has proved valuable in the treatment of various forms of ulcers, in *alopecia areata,* in contusions and in other acute injuries. Minim also offers this light as a substitute for the Finsen light in lupus.

Doctor Hopkins of Brooklyn claims the treatment by the light of the Hopkins lamp is a cure for pulmonary tuberculosis in the first stage, as well as for many cases in the second stage and that it has been of great comfort and has prolonged life in a number of instances in the third stage of the disease. The lamp consists of a 50-ampere searchlight in a brass cylinder, with a French condensing-lens, 18 inches in diameter. It focuses at a distance of about 12 feet. The light passes through a sectional screen of blue glass, two feet square, to cut out the heat-rays and impinges upon the chest of the patient. Half-hour exposures to this light are found to be sufficient.

The German Light-Bath is used for treating the naked body by concentrated light. It consists of a couch in a cabinet or sheet enclosure, with two or more lamps within it comprising from 40 to 80 amperes. This bath of light has proved efficacious in malnutrition, marasmus, and various forms of debility and in neurasthenia and other neurotic affections.

The mercury vapor lamp of Kronmayer, in which the rays are passed through a window of rock crystal, the crystal not filtering out the ultra-violet rays has made it possible to project intense radiations and so produce very violent reactions from short exposures. By careful management it is possible thus to remove angioma, rosacea, patches of lupus, etc. In carbuncles, radiant light and heat may be employed alone to abort the condition if applied in the early stages and for long periods. Light has proved effective also in tuberculosis, peritonitis and other tuberculous conditions.

PHOTOTOPOGRAPHER. See SURVEYING.

PHOTOTROPISM, same as heliotropism (q.v.).

PHRANZA, frän'zą, or **PHRANZES,** frän'zās, **George,** Byzantine historian: b. 1401; d. about 1477. He was chamberlain of Manuel II (Palæologus) and was a warrior and diplomat in the service of Constantine XIII, whose life he saved in the siege of Patras (1429). After the capture of Constantinople by Mohammed II (1453) he escaped to Corfu and retiring to a monastery, wrote his interesting and reliable 'Chronicon' or Byzantine history, covering the period from 1259 to 1477 and the chief authority for the author's own time. There are editions by Alter (1796) and Bekker (with Latin translation 1838).

PHRASE, *in music,* a short division of a composition, in compound time sometimes contained within one measure, but usually consisting of two or more measures, closing with a half-cadence or a cadence. Two united phrases ending in a cadence form a section, and two sections, the first terminating with the dominant, and the second with the tonic harmony, constitute a perfect musical idea. The musical phrase is analogous to the literary sentence; their proper interpretation and rendition, termed «phrasing,» into which the due elements of accent and rhythm enter, is one of the distinguishing characteristics of the art of the vocalist or instrumentalist, without which any musical performance is merely mechanical. The term phrase is applied also to any short passage performed without break, and the irregular phrase qualifies a passage with any unusual number of measures.

PHRENOLOGY (Greek, *phren,* mind; *logos,* discourse), the science which teaches that there exists a relation between the several faculties of the mind and particular regions of the brain, and that these are the organs of those faculties; in accordance with this theory phrenologists chart the cranium of man in sections, each section being taken to represent the seat in the brain of some definite faculty or mental or moral disposition. That the brain as a whole is the organ of mind we should incline to regard as an instinctive judgment were it not that some of the most highly gifted races, as the Hebrews, the Egyptians, nay even

the Hellenes, as is proved by their vocabularies and their literature, recognized various organs and viscera as the seats of the intellective and of the emotional faculties; the heart, for example, was for the primitive Romans the seat of understanding, of wisdom, as also for the Egyptians, the Hebrews, the Greeks; but at the same time it was for them the organ of feeling and emotion. But Pythagoras (6th century B.C.) held the brain to be the seat and organ of understanding; yet Aristotle, 200 years later, taught that the heart is the master organ of life and inelligence, and that the brain is a cold, inert, bloodless organ, the sole function of which is to temper the heart's excessive heat. But for Plato the heart was the chief organ of intellect, and the great naturalists, anatomists, and physicians who lived later adhered to Pythagoras' view despite the very high authority of the Stagirite. Even in the Middle Ages when Aristotle's authority was supreme, the scholastic philosophers rejected his doctrine on this point, and Albertus Magnus, in the 13th century, and very many other philosophers and naturalists after him, divined a localization of faculties in the brain. Albertus saw in the anterior region the seat of judgment or ratiocination, in the medial, that of imagination, and in the posterior region the seat of the memory; and his successors in a similar way distributed the seats of the several faculties of the soul in the different regions of the brain. Hence, Francis Joseph Gall, though justly accounted the founder of modern phrenology, did but revive the ancient knowledge and develop it further. He expounded his views on the subject in lectures at Vienna in 1796 and later, but in 1802 was compelled to discontinue them by order of the Austrian government prompted by the ecclesiastical authorities. Gall had already attached to himself a gifted pupil and efficient coadjutor in the person of John Gaspar Spurzheim, and the pair pursued their investigations in concert and delivered lectures on phrenology throughout France and Great Britain. In both countries they gained enthusiastic disciples not only among the less educated class but among the learned also — such men as Sir George Mackenzie, Archbishop Whately, Laycock, Macnish, Andrew Combe: the last named was universally recognized as the ablest expositor of the doctrine in Great Britain, and its indefatigable propagandist. Phrenological societies sprang up everywhere in England and the United States, and the principles of the science were propounded and defended in a number of periodicals, British and American, the first both in point of time and in authority being the British *Phrenological Journal,* published in Edinburgh and edited by Dr. Combe till his death in the United States, 1847. The popular interest in phrenology which for 30 years or more was at fever heat languished and died away till now phrenological societies are heard of no more and phrenology for years had but one representative in the periodical press of the United States. Fowler and Wells of New York were the last publishers to take an active interest in the science, and Nelson A. Sizer was the last of active phrenologists.

Phrenology, as finally developed, is the work rather of Spurzheim and of Combe than of its first founder, Gall. Gall located 27 special faculties out of the 35 usually recognized; but to Spurzheim is due the credit of having systematized and justified Gall's data and of having enriched the science with important discoveries. Not the least of Dr. Spurzheim's merits is the improvement made by him in the nomenclature of the science: for example, when what in Gall's scheme is called *murder,* Spurzheim calls *destructiveness,* a term which is more comprehensive as well as more exact; or when of Gall's two terms *veneration* and *religion* Spurzheim retains only the first, in which the second is comprised. The 27 faculties identified by Gall are by Gall himself named and numbered as follows: 1, veneration; 2, love of offspring; 3, friendship; 4, courage, self-defense; 5, murder; 6, cunning; 7, the sentiment of property; 8, pride, self-esteem, haughtiness; 9, vanity, ambition; 10, cautiousness; 11, memory of things, educability; 12, local memory; 13, the memory for persons; 14, memory for words; 15, memory for languages; 16, colors; 17, music; 18, number; 19, aptitude for drawing conclusions; 22, wit; 23, poetry; 24, good nature; 25, mimicry; 26, religion; 27, firmness of character. (The numerical figures do not apply to Spurzheim's phrenological chart).

Spurzheim classified these faculties, propensities and other characters as follows:

SPURZHEIM'S CLASSIFICATION AND LOCALIZATIONS.

Spurzheim recognizes two great classes of human faculties, namely:

I. Feelings, divided into:
   1. Propensities, or predispositions only to certain kinds of acts.
   2. Sentiments, or impulses which prompt to emotion as well as to action, and these are either
      a. Lower, common to man and lower animals; or
      b. Higher, peculiar to man.

II. Intellective faculties:
   1. Perceptive faculties.
   2. Reflective faculties.

PROPENSITIES.

1. Amativeness. 2. Philoprogenitiveness. 3. Concentrativeness. 4. Adhesiveness. 5. Combativeness. 6. Destructiveness. 6*a*. Alimentiveness. 7. Secretiveness. 8. Acquisitiveness. 9. Constructiveness.

SENTIMENTS: LOWER.

10. Self-esteem. 11. Love of Approbation. 12. Cautiousness.

SENTIMENTS: HIGHER.

13. Benevolence. 14. Veneration. 15. Conscientiousness. 16. Firmness. 17. Hopefulness. 18. Wonder. 19. Ideality. 20. Wit. 21. Imitation.

PERCEPTIVE FACULTIES.

22. Individuality. 23. Form. 24. Size. 25. Weight. 26. Color. 27. Locality. 28. Number. 29. Order. 30. Eventuality. 31. Time. 32. Tune. 33. Language.

REFLECTIVE FACULTIES.

34. Comparison. 35. Casualty.

Phrenology was popular during the middle of the 19th century, but suffered from the lack of true science displayed by many of its advo-

cates, who assumed altogether too much for it, and made money out of it by charting heads of those interested at from 50 cents to $5 per chart. The most necessary thing for a professor of phrenology was a happy faculty of flattering everybody, and the more they flattered the more people paid to have their heads charted, to get information as to their characteristics. A few men of large perception, like the late Nelson A. Sizer, gave value for the examinations they made, but they appear to have used physiognomy to assist them, and to have been also very shrewd observers, discovering characteristics in half a dozen ways, besides examining the skulls of their subjects. Another blow was given phrenology as anatomy advanced. The study of the brain functions on the dissecting table failed to support the assumptions of the phrenologists and to this day the surgical and medical professions have refused to acknowledge any attainment which shows phrenology, as taught by its professed followers, as being scientifically exact.

Probably the best presentation of the scientific attainments by the professional phrenologists is reflected in the monograph by Sir Arthur Keith in his report upon the skull of Sir Thomas Browne (q.v.), in which he says: «The architecture of the human brain and skull have been worked out by evolutionary Nature on definite and very conservative principles. The skull is the building in which the brain is housed, but it is not erected and finished, as is a government edifice, before the departmental staff comes into residence. The brain and its house, the skull, grow and expand together; the developing brain, as a whole, and also each of its individual departments have the power to enlarge and modify its containing walls of bone according to its needs. The size and form of the skull do depend on the form and size of the brain; and the form and size of the brain do depend on the organization of the central nervous system. Phrenology cannot be called a science until we have exposed the machinery which regulates and co-ordinates the architecture of brain and skull.» And, in concluding the monograph, he says: "To the reader this may appear to be an admission that phrenology is merely a doctrine, not a science. This is not the view I take. Our knowledge of the use of various parts of the brain is only dawning. . . . Until this knowledge ripens, we can only grapple with the grosser features of the brain and the structure in which it is lodged, the skull. The goal which the phrenologist has in view is a knowledge which will make it possible for him to examine the head of a living child by sight, touch, and X-ray transillumination, and to thus form an accurate estimate of the development of its brain as a whole, and of its various parts; and from this knowledge of the brain infer the abilities of the child. The day will possibly come when we can decipher the parts of the brain in the living head, and ascribe with certainty the functional significance to be attached to them; but certainly that day is still far off.

Some observers have a special aptitude for judging of the character of men applying for employment, and putting the right men in the right places—they are natural phrenologists; but it must be admitted that they use other means than examining the heads of applicants. Phrenology was disowned by science because too much was claimed for it, and too much expected. Like physiognomy (q.v.) it is a valuable aid to estimating character.

PHRIXUS, phrĭk'sŭs, *in Greek mythology,* the son of Athamas and Nephele, and the brother of Helle. When about to be sacrificed to Zeus, he was rescued by his mother and carried with his sister to Colchis upon a ram with golden fleece. Helle fell into the sea and was drowned on the way and the waters where it took place were called the Hellespont. It was the fleece of this ram, given to King Æetes, and kept by the king in a garden guarded by a fiery dragon, in search of which Jason went in the expedition of the Argonauts.

PHRYGIA, frij'i-ą, *in ancient geography,* a country of Asia Minor, occupying the central plateau west of the Halys and the interior desert, but otherwise very ill-defined, since the country varied much at different times and in general was an ethnological rather than a geographical term, as it was applied to the district occupied by the Phryges or Phrygians. The region was broken by sharp valleys, was extremely fertile, especially on its western slope, and was rich in gold as is evidenced by the myth of its King Midas. He was said to be the second king of the country succeeding his father Gordius, a common laborer who founded the kingdom, about 800 B.C. The names of Gordius and Midas are frequently repeated in the list of Phrygian kings, and this account of the foundation of the kingdom is scarcely credible. Indeed it seems that a much earlier Phrygian civilization spread over Lydia, Cappadocia and Lycaonia as well as Phrygia, leaving behind it monuments of its peculiar art and a road system later utilized by the Persians. Intercourse with the Greek cities of Asia Minor seems to date from the 9th century B.C., and with the European Greeks, through the colony of Sinope (founded 751) in the 8th century. But 100 years later the Phrygian kingdom was wiped out (680–670 B.C.) by the invasion of the Cimmerians, who seem to have held the country till about 620, when the Lydians conquered Phrygia, to hold it until the conquest of Lydia by Persia. Persia's downfall transferred Phrygia to Macedonia, and it became a part of Pergamus, and in 90 B.C. was incorporated into the Roman province of Asia. Phrygian slaves were highly prized among the Greeks, probably as early as the 5th century.

Ethnologically the Phrygians seem to have been closely related to the Armenians. Both were of Indo-Germanic stock, as has been proved by recent studies on the Phrygian language, which is known to us only from the

scanty remains of widely scattered inscriptions and a few glosses; many of the funeral inscriptions are in Greek, save for the curse at the end on him who "disturbs my bones," which was written in Phrygian. The language, like Armenian, seems to be Iranian in its affinities. Inscriptions in its peculiar alphabet, the exact value of some signs which are still unknown, are found in Lemnos and in Egypt. Some few of its words agree almost exactly with the Greek, and many loan words from the Phrygian seem to be found even in the Homeric dialect. Most of the sepulchral inscriptions alluded to are found on tombs with peculiar conventional pattern of great boldness and skill in design, the figures being mostly of a heraldic type strangely suggestive of Oriental rugs. The most famous of these tombs are those of the early kings, including Midas, in the hills near Sangarius — all apparently were memorials and not actual burial places. The Phrygians seem to have been essentially a rustic people, and their religion was a nature worship, in which the great divinity was Ma or Ammas, the Great Mother, also called Cybele, which seems to have meant "the mountain goddess." Her seats were Dindymus, Sipylus and Ida, and she was the goddess of vegetation and of all life and generation. Her cult passed to Greece in the 5th century, and her black stone image was carried to Rome in 204 B.C. Closely associated with her was Attis, again a divinity of nature's powers of reproduction.

III and IV, 1886, 1890), and Roscher, 'Lexikon der griechischen und römischen Mythologie,' s. vv. Attis, Kybele, Men, etc. (1884 seq.).

PHRYGIAN CAP, or **LIBERTY CAP,** a peaked headdress worn by the ancient Phrygians. Such a cap when placed upon the heads of Greek and Roman slaves became a token of their freedom. Hence it has become a symbol of liberty. The Roman conspirators, after murdering Cæsar, carried it through the streets on a pole and it was stamped on coins. It was also connected with the French Revolution. Louis XVI was compelled to wear it in 1792 in order to show his agreement with the people's desires. In the same year it was made the mark of a "patriot." It is also seen on the head of the Goddess of Liberty, on some of the coins of the United States, and has been adopted by some foreign countries, being inscribed on their coats of arms.

PHRYGIAN LANGUAGE. See PHRYGIA.

PHRYNE, frī'nē, famous Greek courtesan: b. Thespiæ, Bœolia, in the 4th century B.C. She was named Mnesarete, but on her coming to Athens, where she became a flute player and later a hetæra, was called Phryne (literally "toad") "because of her complexion." She grew rich in her profession and became the mistress of the sculptor Praxiteles, who modeled after her his statues of Aphrodite and made two portrait statues of her. Many stories of her are told, the most famous being that of her promise to rebuild from her own purse the city of Thebes on the condition that the city should be inscribed "Destroyed by Alexander; rebuilt by Phryne" — an offer which was declined. Quintilian is the first authority for the story of her trial before the Areopagus, in which her lawyer Hyperides, seeing that he would lose the case, drew her clothes from her breast and shoulder, showing the judges a beauty so perfect as to force them to declare her innocent. During an Eleusinian festival, another story relates that she appeared in the sea bathing in full view of the pilgrims, a theme taken by the painter Apelles for his picture of Aphrodite Anadyomene (that is, "rising from the sea-foam"). In later art Phryne figures in a famous fresco at Pompeii, and in the painting of Gérome (1861), and in the statue by Pradier.

PHRYNICHUS, frĭn'ĭ-kŭs, early Greek tragic poet. He was an Athenian, won his first tragic victory in 511 B.C., and was writing in 476 B.C., at which time his 'Phœnissæ' was presented with much pomp by Themistocles. Besides the 'Phœnissæ,' which was imitated by Æschylus in the 'Persæ,' Phrynichus wrote several works, the titles of nine others having been preserved. His 'Capture of Miletus,' Herodotus says, was the cause of his being fined for thus employing a national calamity, and of a law against tragedies of political content. Phrynichus is said to have been the originator of several improvements in the drama.

PHTHA, thä. See PTAH.

PHTHIOTIS, thī-ō'tĭs, the southernmost of the tetrads of ancient Thessaly and now forming, with Phocis, a nomos, or governmental division of the Greek kingdom. The ancient district, famed as the home of Achilles, included the region about the Othrys range between the valley of the Spercheius and the great plain of Thessaly. The present department, together with Aetoba and Acarnania, Attica and Boeotia, and Euboea, constitutes Central Greece and Euboea; its area is about 1,800 square miles; pop. 193,671. Capital city Lamia.

PHTHISIS, thī'sĭs. See TUBERCULOSIS.

PHYCOCYANIN, PHYCOERYTHRIN, PHYCOPHÆIN, pigments coloring the blue-green, red and brown seaweeds respectively. See ALGÆ.

PHYCOLOGY, that department of botany which treats of the algæ or seaweeds.

PHYCOMYCETES, PHYCOPHYTES. See FUNGI.

PHYFE, fīf', **William Henry Pinkney,** American author: b. New York, 13 June 1855; d. 7 March 1915. He received his education at Columbia College and devoted himself to a study of spelling and pronunciation, on which subject he wrote 'The School Pronouncer; How Should I Pronounce?' 'Seven Thousand Words Often Mispronounced,' subsequently revised to include 10,000 words; again in 1908, 12,000 words, and in 1914, 18,000 words. He was also the author of 'Napoleon, the Return from Saint Helena' (1908).

PHYLACTERY (Gr. *φυλακτήριον*, a receptacle for safe-keeping. The Hebrew word means "frontlet"); a sort of small box containing four passages from the Pentateuch, namely, Exodus xiii, 1–10, 11–16, Deuteronomy iv, 4–9, xi, 13–21. The phylactery or *tephillah* was a small leather case fastened to a band, and each male Jew of 13 years of age and upward wears two of them at morning and evening prayer. One is bound round the head in such a way that the case comes between the eyebrows. In this case are four compartments, each containing a strip of parchment with one of the four passages above mentioned. The other band with a simple phylactery is fastened round the left arm, the little case being turned toward the heart. The practice of wearing these *tephillin* was developed out of the commands in Exodus xiii, 9 and 16, and Deuteronomy vi, 8, and in its present form dates from about the 1st century before the Christian era. In Matthew xxiii, 5, Jesus condemns the Pharisees for making broad their phylacteries. The name phylactery, from a Greek word meaning "to guard," refers to their use as amulets for protection against demons.

PHYLÆ, fī'lē, *in Greek history*, the several tribes of a city or nation, each composed of men who traced their descent to a single common ancestor. The Ionians were made up of four such tribes which settled themselves in Attica, namely the Geleones, the Hopletes, the Agikores and the Argades. They were the foundation of the Athenian state and were divided into three phratries. Solon recognized these four Old Ionic tribes. Cleisthenes organized them into 10 tribes which he called after Old Ionian heroes; and these were again divided into demes. In 307 B.C. two new tribes were added, and these in honor of Demetrius and his father Antigonus were named Demetrias and Antigonis. A 13th Hadrianis was added in honor of the emperor Hadrian (123 A.D.). The Dorians had three tribes, the Hylles, Dymanes and Pamphyles, forming the main body of the state, and in Sparta were divided into 10 Obes.

PHYLARCHUS, fī-lär'kŭs, Greek historian, who flourished about 215 B.C. He was, according to some, an Athenian, according to others an Egyptian. He wrote 28 books of Ἱστορίαι ('Histories'), a work apparently containing accounts of not only Greece and Macedonia, but also Egypt and other contemporary states. It covered the period from the invasion of the Peloponnesus by Pyrrhus to the death of King Cleomenes of Sparta. Polybius and Plutarch attack his credibility, yet Plutarch made extensive use of Phylarchus' work in his own lives of Cleomenes and Aratus. Only a few fragments remain.

PHYLLIS, fĭl'ĭs, *in Greek myth*, a daughter of Sithon, king of Thrace, who from grief at the absence of her beloved Demophon took her own life, and was changed into a leafless almond tree. When Demophon returned and flung his arms around the tree it burst into full leaf.

PHYLLITE, (1) a mineral related to or a variety of ottrelite, found as micaceous scales in the mica schist of various parts of Massachusetts and Rhode Island. Hardness six to seven; color greenish-gray to black. In composition a hydrated silicate of iron, aluminum, and manganese. (2) A finely crystalline metamorphic rock which is a fine-grained mica schist and may be considered a transition type between an ordinary mica schist and a slate.

PHYLLIUM. See LEAF-INSECT.

PHYLLOCARIDA, a name given by Packard to the group of crustaceans called *Leptostraca* by other authors. But a single genus (*Nebalia*) is known, a small shrimp-like form occurring in seas of moderate depth. The group is characterized by having a bivalve carapace, 21 body-segments, of which eight are in the abdomen, and leaf-like thoracic feet resembling those of the *Phyllopoda*.

PHYLLOPODA, the most primitive group of existing crustacea. The name refers to the feet, which are broad leaflike structures, the thoracic appendages being unjointed, while those of the head are typically arthropodan. The number of segments of the body varies between very wide limits, those of the abdomen being without appendages. In all except the *Branchipidæ*, a carapace is developed, either as a broad oval plate covering the thorax, or as a bivalve shell closed by adductor muscles like a clam. The group is divided into the *Branchiopoda* (q.v.) with numerous segments, most of the species being inhabitants of fresh water (see APUS); and the *Cladocera* in which the segments number less than a dozen, the species being some inhabitants of fresh water, others of the sea. Most of the fresh-water species are normally parthenogenetic (see PARTHENOGENESIS), the males appearing only at rare intervals; indeed the males of some species are unknown. Many are inhabitants of pools which dry up in hot weather: and it has been found that with some species the eggs need to be dried before they will develop. Many species lay two kinds of eggs, thin-shelled summer eggs and thicker-shelled winter eggs. In the *Cladocera* the dorsal part of the carapace serves as a brood-pouch, the eggs here undergoing their development, sometimes nourished by fluids secreted by the mother. The species of *Artemia* are remarkable from the fact that they live in salt springs and lakes, or in tubs and vats filled with brine, but are unknown in the sea or in fresh waters. (See BRINE SHRIMP). Consult Packard, A. S., 'North American Phyllopod Crustacea' (Washington 1883); id., 'Text-book of Zoology' (11th ed., New York 1904).

PHYLLOTAXIS, *in botany*, the arrangement of leaves on a stem, three common positions being opposite, alternate and verticillate. See LEAVES.

PHYLLOXERA, or **VINE-PEST**, an American aphis (*Phylloxera vastatrix*), destructive to grapevines. It has four forms: sexual, leaf-gall, root and winged. The sexual female lays an egg upon the vines during the autumn. About the time the buds open, the larva hatched from this egg forms a gall upon the upper surface of a leaf and in about two weeks commences egg-laying, soon producing from 500 to 600 eggs within the gall it has made. The young which appear in about a week disperse to other parts of the vine and form galls like the first. During the summer six or more generations are produced and the leaves may

be completely covered with galls. The last brood produced before cold weather migrates to the roots where the insects hibernate until spring. During the growing season of the second year several generations of wingless females are produced upon the rootlets which swell more or less at the points of attack. In early autumn these root forms may produce winged females, which fly to the vines and lay eggs to continue the life-cycle. Often, however, no winged forms may be produced for several years, the root forms being capable of continued reproduction under favorable conditions. Flight is not the only means the insect has for distribution; it may be carried by vines transplanted from infested vineyards to new ones, by birds and insects to whose bodies the leaf form may cling; by winds which carry the leaf form either with leaves torn from the vines or otherwise; and through the crawling of the root form through cracks in the earth.

Though the insect is an American species, it has done little damage upon American varieties, since these are more resistant, probably because of the thicker bark of their roots and their robust habit of growth. But upon the European varieties of *Vitis vinifera* the root-form is especially troublesome. It was introduced into France upon American vines about 1859, and not only in France but throughout the grape-growing sections of Europe it quickly spread and did enormous damage. It is now known in nearly all grape-growing countries of the world. It is believed to be responsible for the failures of European varieties in America where, however, it was unknown at first except in the Rocky Mountain region, and then, somewhat later, in California upon European vines. Since the root form, which is seldom seen, is the destructive form, methods for combating it were rarely satisfactory. The most frequently tried were probably bisulphide of carbon injected into the soil and flooding the ground. The one preventive remedy which has proved effective is the grafting of the European varieties upon the roots of the American varieties *V. rupestris* and *V. riparia*. *V. labrusca* was also hopefully tried but was found as susceptible to the pest as *V. vinifera*. Consult: Annand, P. N., 'A Contribution toward a Monograph of the Phylloxeridae of North America' (Palo Alto, Calif. 1928); Davidson, W. M., 'The Grape Phylloxera in California'; issued as U. S. Department of Agriculture Bulletin No. 903 (Washington 1921); Husmann, G. C. F., 'Testing Phylloxera-resistant Grape Stocks' (Washington 1930). See GRAPE INSECT-PESTS.

PHYLOGENY, the development or evolutionary history of an animal group considered as a whole. This branch of knowledge is based on the study of embryology of animals and the facts thus brought to light, which are supplemented by the study of paleontology. See EVOLUTION; PALEONTOLOGY.

PHYSA. See POND-SNAIL.

PHYSALIA. See PORTUGUESE MAN-OF-WAR.

PHYSIC-NUT, or **CURCAS,** the seed of *Jatropha purgans,* or the plant itself, a tropical shrub belonging to the order *Euphorbiaceæ*. These seeds have strong emetic and purgative properties, due to a fixed oil which is expressed and used in medicine under the name of jatropha-oil. The seeds of another species (*J. multifidus*) are called French or Spanish physic-nuts, and these yield oil of pinhoen. See JATROPHA.

PHYSICAL CONSTANTS. See UNITS OF MEASUREMENT; WEIGHTS AND MEASURES.

PHYSICAL CRYSTALLOGRAPHY treats of the physical properties of crystals and their determination. In general any measurable property will yield results varying with the direction and alike only in directions which are structurally equivalent. If these results are represented by straight lines of proportionate length in the given directions they determine a closed surface which in symmetry and dimensions represents that property in that crystal.

The physical characters may be subdivided into those which depend upon cohesion and elasticity, and upon the action of radiant energy (light, heat, magnetism and electricity).

The Properties Dependent upon Cohesion. — The resistance opposed by a crystal to forces tending to separate its particles is shown by various important properties, as cleavage, gliding, parting, percussion-figures, etch-figures, corrosion and hardness. Of these *cleavage* has been described, see CLEAVAGE, and *hardness* is discussed under the article MINERALOGY.

Gliding is the tendency of the particles to slip or glide without separation parallel to a so-called gliding plane, which is always a possible crystal face, when pressure is exerted in a certain direction. Thus if a slender crystal of stibnite supported at the ends is pressed downward with a dull knife edge, it is bent at this point without affecting the other parts. The gliding may be accompanied by a revolution of 180 degrees bringing a part of the crystal into twinning position. Unlike cleavage planes, which are at right angles to directions in which the particles are furthest apart, gliding planes are at right angles to directions in which the particles are very close together.

Parting.—The planes along which gliding has taken place often become planes of easy separation and are then called parting-planes. Parting resembles cleavage, but is distinguished by the fact that it takes place only in certain definite planes, those of the molecular disturbance, while cleavage may be obtained in any part of the crystal in the given direction.

Etch figures.— When a crystal is attacked by any solvent the action proceeds with different velocities in crystallographically different directions, and if stopped before the solution has proceeded far, the crystal faces are often pitted with little cavities of definite shape usually bounded by minute faces.

The figures, whatever their shape, conform in symmetry to the class to which the crystal belongs and as the faces rarely belong to limit forms common to several classes, etch figures are very useful in determining the true symmetry of the crystal.

Etch figures are alike on faces of the same crystal form and generally unlike on faces of different forms.

Corrosion.— The unequal rapidity of solution in different crystallographic directions is sometimes studied by immersing a crystal in a solvent. This may result in the development of new faces conforming in position to the sym-

metry of the crystal. Sometimes a sphere is cut from the crystal and submitted to the action of the solvent. Thus a sphere of quartz subjected to the prolonged action of hydrofluoric acid was attacked rapidly in the direction of the vertical axis but scarcely at all in the direction of the horizontal axes, the resulting form being a subtriangular lens.

Percussion Figures.— Cracks parallel to crystallographic directions are sometimes developed by pressing or tapping a conical point against a face of a crystal. Examples are mica and common salt.

The Properties Dependent upon Elasticity. —If rods of the same length, breadth and thickness are cut from different parts of the same crystal and subjected to equal strains, they are found to undergo different extensions, and if, from the resulting coefficients of extension for all directions, the extension surface is constructed, this, while often a very complex shape, is found always to be symmetrical to the axes and planes of symmetry of the crystal.

Pressure in different directions will modify the optical characters of a crystal. For instance, isotropic crystals may be made to yield uniaxial or biaxial phenomena according to the direction in which the pressure is applied.

The Optical Properties of Crystals.— Although the electromagnetic theory of light is now generally accepted, the terminology of the older undulatory theory is still conveniently used in discussing the optical characters of crystals. It is assumed that while the direction of advance in a homogeneous medium is in straight lines, the transmission is due to vibration (or waxing and waning of force) at right angles to this direction of advance. This may be called a vibration and designated in direction and intensity by a straight line. The advance during a complete vibration is called a wave length and determines the color of the light while the amplitude of the vibration determines the intensity.

The properties of light are elsewhere described (see LIGHT). Those most used in the study of crystals are refraction, double refraction, polarization and absorption. In other words, because crystals on account of their structure retard the transmission of light differently in different directions, both with respect to the velocity of transmission and the quantity transmitted, these properties of transmission are utilized to determine crystalline structure.

Refraction.— Rays of light in passing *obliquely* from one medium to another in which the velocity of transmission is different are bent or refracted. If the velocity is lessened the bending is *toward* the perpendicular to the surface of contact, if the velocity is increased the bending is *away* from the perpendicular.

The ratio of the velocities of light in the two media is called the *index of refraction* of the second medium with respect to the first and it has been proved that whatever the angle of incidence, the ratio of the sines of the angles of incidence and the angle of refraction is constant for the same two media and equal to this index of refraction. That is, $n = \frac{\sin i}{\sin r} = \frac{V_1}{V_2}$

Double Refraction.— In 1679 Erasmus Bartholin observed that the objects viewed through iceland spar appeared double, one image conforming to ordinary refraction, the other not so conforming. For instance, one of the two rays had a fixed index of refraction (1.658 for yellow light) while the index of the other varied for different directions of transmission from 1.658 to 1.486. As early as 1678 Huyghens showed that the optical behavior could be represented by a double shelled surface like that later described under optically uniaxial crystals.

Double refraction could be proved for only a few crystalline substances by the direct observation of double images. Other methods, however, prove that it is a general property of all crystals except those of the isometric system.

Polarized Light.— In ordinary light the vibrations are assumed to take place at right angles to the line of transmission but in any plane. Malus discovered that light reflected from inclined plates of glass, when viewed through the doubly refracting iceland spar, gave images which differed in intensity, and that for certain positions of the iceland spar one or the other image disappeared. Light so modified is said to be polarized and the vibrations are considered to take place in one plane only.

The rays transmitted by any doubly refracting crystal consist of polarized light and for any direction of transmission the planes of vibration of the two emerging rays are at right angles to each other.

Absorption and Pleochroism.— Light passing through any substance is partially absorbed the amount increasing with the thickness. If the light is composite the component lights of different wave length may not be absorbed in the same ratio and the substance will appear of the color due to the unabsorbed portions of the components.

In doubly refracting crystals the two rays transmitted in any direction are apt to undergo different absorptions and may emerge of different color and intensity. Furthermore in different directions in the same crystals the so-called "twin colors" may notably differ and in such a case the "pleochroism" is observable by the eye alone. Thus a crystal of iolite appears bluish in one direction and yellowish in another.

The Optical Classification of Crystals.— According to their optical behavior crystals may be classified as 1. Optically isotropic, 2. Optically anisotropic uniaxial, 3. Optically anisotropic biaxial.

Optically Isotropic Crystals.— Isometric crystals show the same optical properties in all directions, yielding in all directions the same index of refraction and the same rate of absorption. They are singly refracting or rarely circularly polarizing.

Optically Anisotropic Uniaxial Crystals.— In tetragonal and hexagonal crystals the optical behavior varies with the direction, the principal crystallographic axis is also an axis of optical symmetry, for in all directions equally inclined to it the same optical tests are obtained. It is a direction of single refraction or of circular polarization.

The optical properties of a uniaxial crystal are best understood by considering the shape of the Ray Surface, which consists of two shells with a common centre. One is a sphere, the other an ellipsoid of revolution, each passing through points on the rays determined by the velocities of transmission.

Evidently for every direction except that of the optic axis *two* rays are transmitted, an ordinary, with a velocity indicated by the sphere radius, and an extraordinary, with a velocity indicated by *the corresponding radius vector of the ellipsoid*, and the greatest difference of velocity exists for the direction of transmission at right angles to the optic axis.

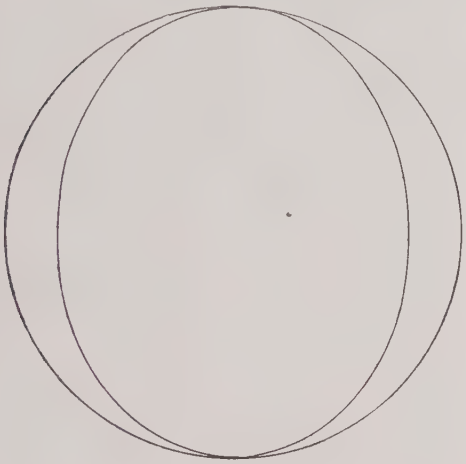

FIG. 1.

The spherical shell may surround the ellipsoid shell or vice-versa. The former combination is called a positive ray surface (Fig. 1), the latter a negative (Fig. 2).

The Optically Anisotropic Biaxial Crystals.— In all orthorhombic, monoclinic and triclinic crystals, the optical behavior varies with the direction, and while there are no true optical axes, there are, for monochromatic light and constant temperature, two directions of single refraction which are called optic axes from analogy with the direction of single refraction in the uniaxial crystals.

The ray surface consists of two intersecting shells symmetrical only to three lines at right angles and to three planes each through two of these lines. Two of the three lines are the vibration directions of the fastest ray and the slowest ray. It may be noted that when planes or axes of geometric symmetry exist they coincide with planes or axes of optical symmetry.

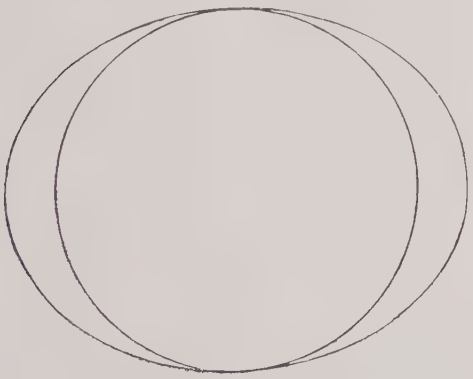

FIG. 2.

If the vibration directions of the fastest and slowest ray are denoted by X and Z respectively and a direction at right angles to these by Y, the shape of the ray surface may be judged from the shape of the principal sections XY, XZ and YZ.

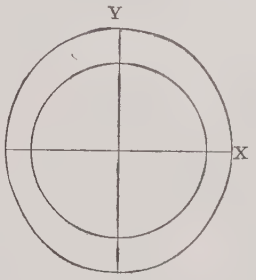

FIG. 3.

The section XY (Fig. 3) cuts the two shells of the ray surface as a circle within an ellipse with radius, major and minor axes respectively slowest, fastest and intermediate velocities, while the section YZ (Fig. 4) cuts the two shells of the ray surface as an ellipse within a circle with radius, major and minor axes respectively fastest, intermediate and slowest velocities.

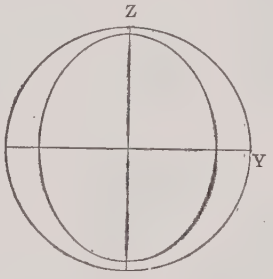

FIG. 4.

The section XZ, the plane of the optic axes, cuts from the ray surface an ellipse and a circle which intersects the ellipse in four symmetrically placed points, E (Fig. 5). The radius, major and minor axes are respectively the intermediate, fastest and slowest velocities.

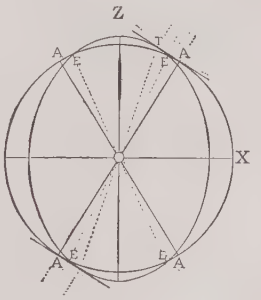

FIG. 5.

Near but not *at* the points E common tangent planes can be drawn to each shell. The directions, AA, normal to these common tangent planes are directions of single refraction, the so-called *optic axes*. The acute angle between these is called the *optic axial angle*.

As in the uniaxial ray surfaces there are two types, the described sections being those of a *positive* ray surface with Z bisecting the *acute* angle between the optic axes; when X bisects this angle the ray surface is said to be negative.

Determining the Optical Properties of Crystals. *The Light Used.*— In general the light used is polarized, as the effects of the crystalline structure upon this are more readily studied. Some of the tests also require the use of monochromatic light, that is of light of one definite wave length, while other tests are made with white light.

Obtaining the Polarized Light.— Although occasionally produced by reflection of common light at a definite angle, or by double refraction and absorption, as in the simple polariscope, known as the tourmaline pincers, the usual method is by sending common light through one of the various forms of «nicols» prisms, the original form of which described by Prof. William Nicol was constructed as follows: A cleavage prism of transparent calcite (Fig. 6) is cut diagonally along the line H H and then the two parts are cemented together with Canada balsam. The end faces are ground off slightly so that an angle of 68 degrees is formed. (See Fig. 6). The ordinary ray *o* with an index of refraction of 1.66 is totally reflected. The extraordinary ray *e* with an index of refraction of 1.54 (practically that of the balsam) passes through the prism with little, if any, change. The plane of vibration of the nicol is assumed to be through the shorter diagonal.

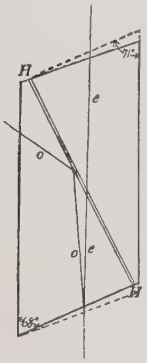

FIG. 6.

The Polarizing Microscope.— The various polariscopes of former days have been replaced almost entirely for crystal study by the polarizing microscope the simplest form of which necessarily includes the essentials of an ordinary microscope (a stand supporting a tube carrying objective and ocular, a platform or stage and means of focusing and illuminating), and in addition a nicol, «the polarizer,» below the object, to polarize the incident light, and another above the objective, «the analyzer» arranged to be thrown in or out and «crossed» with respect to the polarizer.

To these essentials may be added many devices and attachments for special purposes.

The tests usually are made in known crystallographic directions, preferably upon «plane parallel» sections or through natural faces at right angles to the desired direction of transmission.

«*Crossed Nicols.*»—When the vibration directions of the upper and lower nicol are crossed, the polarized light from the lower nicol cannot penetrate the upper nicol and the field is dark. If when a transparent section of a crystal is placed on the stage and revolved, the field is still dark, the direction of transmission is one of *single refraction,* but if during the rotation the field is in general illuminated, but is dark for four positions, 90 degrees apart, then the direction of transmission is one of *double refraction.*

These four positions of darkness or «*Extinction*» occur when the vibration directions of the two polarized rays emerging from the section are parallel to those of the two nicols for then only the polarized light from the lower nicol is transmitted by the section with unchanged vibration direction and cannot pass through the upper nicol.

With crossed nicols and a doubly refracting crystal section the light effect at any point is due to the combined effect of two components with vibrations in the same plane. In general they have been unequally retarded during transmission and may supplement or neutralize each other. If for instance monochromatic light is used and the difference in retardation of the two rays is denoted by $\triangle$ and the wave-length of light by λ then:

If $\triangle = \lambda, 2\lambda, 3\lambda, \ldots, n\lambda$ the two components following the same path will oppose and exactly neutralize each other, the light will be stopped and darkness will result for all positions of the crystal section.

Similarly if $\triangle = \frac{1}{2}\lambda, \frac{3}{2}\lambda, \frac{5}{2}\lambda$, etc, the maximum illumination results.

Since $\triangle$ increases with the thickness these facts may be shown by use of a thin wedge of a double refracting crystal. Under low magnification this will show with monochromatic light equidistant dark bands with brightest illumination midway between them. When white light is used instead of monochromatic light «*interference colors*» result because for any section $\triangle$ may be at the same time: (*a*) approximately a multiple of the wave-length of light of one or more colors, which would, therefore, be shut out: (*b*) closely an odd multiple of the half wave-lengths of other colors leaving these at nearly their full intensity, and (*c*) intermediate, with still other colors.

For any value of $\triangle$ there is an absolutely fixed interference color and as these to some extent repeat periodically they are conveniently divided into «orders» the transition color between orders being a sensitive violet so-called because very minute changes in $\triangle$ result in decided changes to blue or red. The first, second and third orders end respectively at $\triangle = 575$, 1,130, 1,652 millionths of a millimeter.

Determining the Fact of Single or Double Refraction.— If with crossed nicols and the crystal section on the stage the field remains dark throughout the rotation of the stage the crystal is singly refracting in the direction of transmission. If the field is dark at intervals of 90 degrees and elsewhere illuminated the crystal is doubly refracting.

Determining Indices of Refraction.—Accurate determinations require monochromatic light, constant temperature and, except in isotropic substances, those directions of transmission which yield the *principal* indices. The more used microscopic methods are those of Becke and Van der Kolk both of which involve a comparison with the known indices of liquids.

Becke's method is based upon total reflection at an approximately vertical boundary between two substances and the consequent concentration of light upon the side of the substance with the higher index of refraction. After focussing sharply upon a fragment or grain with an approximately vertical boundary or edge and surrounded by the liquid, the objective is slightly

raised, giving the effect of a bright band moving into the denser substance.

Van der Kolk's method is better for irregular fragments and is based upon the behavior of the fragment in obliquely incident light. With proper adjustments approximately lens-shaped fragments become more strongly illuminated on one side or the other according as their indices of refraction are greater or less than that of the surrounding liquid.

Accurate determinations of the principal indices of refraction are often preferably made by the "prism method" involving the measurement of the "angle of least deviation" and of the prismatic angle. Up to a value of about 1.8 they are very conveniently made by the use of refractometers based upon the principle of total reflection, in which the indices of refraction can be rapidly determined upon polished or natural surfaces from a millimeter in diameter up.

In a much used type the surface of contact is the diametral plane of a glass hemisphere of very high index of refraction, the crystal surface is placed on this with a drop of some liquid also of high index. The diffused light from one side is in part totally reflected and the "limit line" found by a telescope. The index is calculated from the angle at which the telescope obtains the adjustment

Determining Birefringence.— The birefringence or strength of double refraction of any doubly refracting crystal is the difference between its maximum and minimum indices of refraction. If these indices can be determined to the third decimal their difference may be taken as the birefringence.

In practice the birefringence is usually determined from the retardation $\triangle$ and consequent interference color and the thickness of the section, by the relation $\triangle = t(n_1 - n)$.

The retardation $\triangle$ can be measured with great accuracy by compensators. The thickness determination is less accurate.

The function of the compensator, which in its simpler form is a wedge of doubly refracting crystal, is to lower the value of $\triangle$ *by known amounts* until $\triangle = 0$.

Determining Extinction Angles.— The angle between an extinction direction and some recognizable crystalline direction, cleavage, crack, edge, twin plane, etc., is called an extinction angle of the section.

The best general method is to carefully determine the position of the crystalline direction, then rotate the stage clockwise until the field is dark at some reading a. Continue the rotation until the field is light, then turn back counter clockwise to some reading a' where the field is again dark. The reading halfway between is near maximum darkness.

Test plates are also used which between crossed nicols develop some sensitive interference color. This color is not changed when the section being tested is in its extinction position, but is notably changed for any other position.

Determining Pleochroism —Pleochroism may be determined with the polarizing microscope as follows:

The extinction directions are found and then the upper nicol is pushed out and the colors for the two extinction positions noted and compared. These positions give the maximum difference in color for the direction of transmission. The pleochroism may appear as a change in color or a change in the shade of the same color.

It is sometimes more satisfactory to observe the "twin" colors side by side by use of a dichroscope which in its essentials is a cylindrical casing with a rectangular hole at one end and a lens at the other and between a rhomb of calcite of such a length that the two images of the hole are *just* in contact.

The section is held close to the rectangular hole and the instrument rotated until the two images are alike in color. Midway between two such positions the colors differ most.

Determining Uniaxial or Biaxial by Interference Figures.— By introducing a convergent lens below the stage of the microscope polarized rays are sent through the section in a great number of directions and a simultaneous picture is obtained of the interference phenomena due to the varying structure in all these directions. Usually a high power objective is needed and the so-called interference figure may be seen by removing the eye-piece and looking down the tube or by retaining the eye-piece and using suitable extra lenses.

No interference figure is obtained from any section of an *isotropic* (*isometric*) *crystal.* The field remains dark.

Uniaxial Crystals give their most characteristic interference figure when the section is at right angles to the optic axis. This figure consists of a dark cross, the arms of which, called

FIG. 7.

the "isogyres," intersect in the centre of the field and remain parallel to the vibration directions of the nicols during rotation of the fragments. It is due to those rays which then have their vibration planes parallel to the nicols. As the stage is rotated successive rays come into these positions, maintaining the same effect.

With monochromatic light the field will be of the color used, but if the section is not too thin, the centre of the black cross will be surrounded by concentric dark circles, corresponding to rays for which $\triangle = \lambda, 2\lambda, 3\lambda$, etc.

With white light the concentric circles will be color rings, arranged strictly in the order of the interference color.

Biaxial Crystals yield characteristic interference figures both with sections normal to an optic axis and with sections normal to the bisectrics X and Z. In the former the isogyre is a single black bar, essentially straight, when the trace of the plane of the optic axes coincides with the vibration direction of either nicol, but for all other angles of rotation it is curved and resembles one arm of an hyperbola. This arm rotates in the opposite direction to the rotation of the stage.

If the section is not too thin there will be black and often nearly circular interference bands with monochromatic light, and colored curves with white light corresponding to $\triangle = \lambda, 2\lambda, 3\lambda$, etc.

Sections normal to a bisectrix yield an interference figure in which the "isogyres" appear as two dark bars or brushes. For the so-called normal position (Fig. 8) one bar connects the points of emergence of the optic axes, the other is a thicker, lighter band at right angles to the first and midway between the axes.

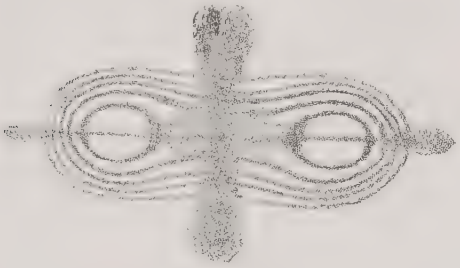

FIG. 8.

If the stage is rotated the straight bars seem to dissolve into an hyperbola, the vertices of which are the loci of the optic axes and the branches of which rotate in the opposite direction to the rotation of the stage.

With convergent monochromatic light there will be, in a field of the color used, black closed curves around the loci of the optic axes corresponding to $\triangle = \lambda, 2\lambda, 3\lambda$, etc. If white light is used isochromatic curves result, but the interference figure may be much more complex than with monochromatic light as neither the axial loci nor the isogyres nor the curves of equal retardation coincide for different wave lengths. The angle between the optic axes may be obtained from the last-described interference figure.

Under favorable conditions interference figures obtained with white light will serve to distinguish between the orthorhombic, monoclinic and triclinic systems, for they conform in shape and distribution of color to the symmetry of the system. With orthorhombic crystals the figure will be symmetrical to the line joining the optic axes, to the line through the centre at right angles thereto and to the central point, with monoclinic crystals the figure will be symmetrical to only one of these and with triclinic crystals to none.

Interference figures furnish a ready means for ascertaining whether the ray surface is positive or negative.

Thermal Properties of Crystals.— Heat rays differ from light rays in their relatively greater length, but may be reflected, refracted, doubly refracted, polarized and absorbed, and it is possible, though difficult, to determine a series of thermal constants for crystals.

Conductivity.— Crystals conduct heat with unequal rapidity in different directions. If a crystal face or cleavage surface is coated with an easily melted wax and touched with the point of a hot wire the wax will melt in a circle with either an *isometric* crystal or a basal section of a hexagonal or tetragonal crystal. All other sections will yield ellipses varying in eccentricity and in position of axes.

Expansion.— When a crystal is uniformly heated, directions crystallographically alike expand in the same proportion, but directions unlike do not. This is shown by the fact that certain interfacial angles are changed, others are not, and the expansion may be accurately measured for any direction, but the methods involve apparatus of great precision and cost.

The Magnetic Properties of Crystals.— All crystals and indeed all substances are to some extent either attracted or repelled when placed in the field of a powerful electromagnet. Those that are attracted are paramagnetic, those repelled, diamagnetic. The strength of the magnetization varies with the direction in crystals, and so far as studied the magnetic relations are analogous to the optical relations with the curious exception that the isometric crystals of magnetite are not magnetically isotropic, but show different magnetic intensity in different directions.

Electrical Properties of Crystals.—*Electric waves* are like light waves; they travel with the same velocity, exhibit the phenomena of reflection, refraction and polarization and differ only in much greater length. Bose has described an electric polariscope, with which it may be possible to test opaque crystals as we now test transparent crystals.

Electric Conductivity.— In the few tested crystals there has been found a dependence of electric conductivity upon crystallographic direction, conforming to the thermal conductivity.

Pyroelectricity.—Change of temperature will develop electric charges in certain classes of crystals. Usually the crystal is heated and allowed to cool. During the cooling of the crystal positive charges collect at the so-called *antilogue* pole and the negative charges at the *analogue* pole.

Piezoelectricity.— Similar charges are developed by pressure, for instance tourmaline compressed in the direction of the vertical axis develops a positive charge at the antilogue end and a negative charge at the analogue end, or precisely the charges which would result from cooling a heated crystal.

PHYSICAL SOCIETY, American, a society affiliated with the American Association for the Advancement of Science (q.v.). It was founded in New York, 20 May 1899. From that date to June 1902 it published quarterly a 'Bulletin.' After that the proceedings of the society and the papers read at its meetings were published in *The Physical Review,* a monthly founded in 1893 and published with the assistance of Cornell University at Lancaster, Pa., and Ithaca, N. Y. In January 1913 this publication was taken over by the society which has continued its regular monthly issue. Since 1925 the society has published its bi-monthly *Bulletin* in New York. In July 1929 publication of a supplement to the *Review* was begun in Minneapolis. This is issued quarterly under the title *Reviews of Modern Physics.*

PHYSICAL SOCIETY OF LONDON, The, a learned organization established on 14 Feb. 1874, having for its object the advancement of a knowledge of physics. The society publishes 'Proceedings' bi-monthly from December to August. Its headquarters are at the Imperial College of Science and Technology, London.

PHYSICAL TRAINING, a term used to indicate the systematic development and maintenance of bodily power and health. In the broad sense it includes gymnastic and athletic exercise, active sports, personal, public and school hygiene. While the term is often used in its broad sense as health training, this article has special reference to physical exercise as related to this.

Systematic training of the body has been followed in some form by probably every nation and race, savage and civilized. In the past it has taken the varied forms of training for warfare through exercise for developing endurance, strength and skill; recreative and competitive sports; gymnastic dances for religious, martial or recreative purposes, and remedial exercises for the cure of disease, often associated with religion and administered by the priesthood. The highest development in many ways that the subject has ever known was in ancient Greece, where athletic games held a place in the political, religious, intellectual and artistic life of the country that made them one of the greatest human institutions in history. (See ATHLETICS; GAMES). The physical training of women in ancient Greece consisted mostly of dancing and ball-playing, though the women of Sparta were not allowed to marry until they had given a public exhibition of proficiency in gymnastics. After its decline in Greece physical training next arose to the dignity of an institution in the age of chivalry when physical strength and prowess were again apotheosized for noble uses. (See GAMES). Following this, development of the body fell under the ban of an ascetic age, where it remained until early in the 19th century despite the protests of such philosophers and reformers as Rabelais, Montaigne, Rousseau, Pestalozzi, Luther, Milton and Locke. At the time mentioned began a renaissance of physical training out of which has grown, side by side with the continuance of athletic sports, the modern gymnasium, a wholly unique institution in its construction, equipment, and the kinds of exercise adapted to it. This exercise includes gymnastics proper, with and without apparatus, games, gymnastic and folk dancing and athletics. With the growth of cities, massing large numbers of people in limited space and curtailing facilities for outdoor exercise, the gynasium has come to mean, not only a preparation for competitive sports, but for thousands of people the only opportunity for vigorous, all-over bodily exercise. At the same time there has developed a scientific and educational understanding and application of the subject in marked contrast to earlier methods. Exercise in its early forms, as inspired by considerations of religion, warfare or competitive sport, was used with a purely empirical knowledge of its effects. With the development of physiology, psychology and related sciences, has come a closer analysis and classification of exercises for their effects upon the physiological functions, a clearer knowledge of the relation of exercise to psychological and moral development, its adaptation to individual needs, and its use as an instrument of education. Germany and Sweden were pioneers in this modern advance of the subject, and the principles and methods there developed have had a profound influence upon the physical training of other European countries and America.

German gymnastics have been developed in societies organized into the Turnerbund, which is the largest organization for gymnastic purposes that the world has ever known. It was founded about 1810 by Friedrich Ludwig Jahn (1778–1852), who invented the mode of exercise known as turning, and who is called the Father of German Gymnastics. The inspiring expressed motive for Jahn's work was patriotism — the development of strong men for the "protection of the fatherland." No institution of physical training since the days of ancient Greece has had such a popular following as the German Turnerbund. Indeed, it bears strong analogies to the Greek institution. Among these is the combination of intellectual, artistic and social interests with physical training. For children there are, in many Turnvereine, classes in drawing, modeling, needlework and literature. The adults have debating societies and choral and dramatic clubs. The social element is very strong. In both Germany and the United States the German turners have a meet or festival every four years, when thousands of participants from all parts of the country contest for honors in gymnastics, athletics, debating, singing, etc. Prizes of laurel or oak leaves, or diplomas, are awarded for these contests. Jahn and his pupils, building upon a collection of exercises made by Gutsmuths (1759–1839) invented a number of pieces of apparatus and exercises to be performed upon them. Much of this German work calls for the sustaining of the weight of the body upon the arms, as in using the horizontal and parallel

bars, traveling and flying rings. The vaulting horse and buck, balance boards, ladders and climbing poles are also prominent in German gymnastics. Freehand gymnastics (namely, without apparatus) and work with light, movable apparatus, such as wands, dumb-bells and Indian clubs, were developed and adapted to schools by Adolph Spiess (1810–58). The establishment of gymnasiums for secondary schools was decreed by the Prussian government in 1844, and for elementary schools for the people in 1860. The Royal Central Gymnastic Institute for training teachers of gymnastics for the army and the schools, was established by the government in 1877. Technically, as introduced in the United States, German gymnastics partake of the empirical character of earlier forms of exercise. The work is classified as tactics, calisthenics, fancy steps, apparatus work, popular gymnastics, games and plays. Within these divisions further classification is according to external features, as, exercise on the upper side of the ladder, on the lower side, outer side, etc. The progressive arrangement of exercises is according to neuro-muscular skill, advancing from simple to complex movements. The capacity of pupils is also determined on the general lines indicated by their separation into classes of children, men, women and old men. Almost all possible movements are permissible, and the ingenuity of teachers has resulted in a large variety of exercises. Indeed, interest and enjoyment — work under the guise of youthful happiness and sport — mark the general spirit of the turner gymnastics. Games for both adults and children are a prominent feature, and for women and children, figure marching with dance steps and singing, called roundels or reigen. The method of teaching and conducting work is almost invariably imitative, the pupils' movements being largely reflex and automatic. This, with the use of apparatus, gives an objective trend to the mental attitude of pupils which reduces mental tension to a minimum. The musical genius of the German people is manifest in its gymnastics, not only in the frequent use of musical accompaniment, or, in the absence of music, of inspiring rhythms beaten out by the instructor, but, in a larger sense, in the artistic arrangement of drills or series of exercises. These are often constructed around a given exercise which serves as a theme on which variations are arranged, working up, as it were, to a climax, and returning at the close of the series to the initial movements. This artistic bent shows in *ensemble* effects used for their appeal to the eye, as when alternate lines work in opposite directions, or a program is closed with a tableau or pyramid of performers.

Gymnastics in Sweden are also "the lengthened shadow of one man"— Peter Henry Ling (1776–1839). While never attracting a popular following like German gymnastics, those of Sweden are also under government auspices and are universally used in the schools and the army, while since 1814 a Roval Gymnastic Central Institute for the training of teachers has been maintained at Stockholm by the government. Ling put gymnastics into pedagogical, military, medical and æsthetic divisions. He brought the subject within the scientific trend of the century by a careful study of the effects upon the body of various positions and exercises, and their classification according to these effects. Developments in physiology have modified some of Ling's conclusions, but the underlying principles remain. He invented a number of pieces of fixed apparatus, notably the stall bars, Swedish horizontal bar (boom) and vaulting box. These pieces of apparatus admit of less freedom and variety of motion than the German apparatus, but lend themselves to more closely graded mechanical progression in the exercises. No light, movable, or so-called calisthenic, apparatus is used in the Swedish work, but much is made of free-hand gymnastics. All exercises are carefully selected for their effects upon the physiological functions or bodily posture. The latter is especially emphasized. No exercises are admitted which even temporarily constrict the chest, embarrass the respiration or "produce continuous pressure upon the large vascular or nerve trunks." Static contraction of the muscles is much used, however, in holding one part of the body in a given position (as bending the trunk forward) while another part (as the head or arms) is exercised. All Swedish gymnastics are taken to command, music being entirely eschewed. These commands are extremely analytical, practically nothing being left to the initiative of the pupil or to the sub-conscious processes of muscular co-ordination. Many Swedish instructors teach new exercises entirely from command or verbal description as distinguished from imitative methods of presentation.

As introduced in the United States Swedish gymnastics have been characterized by an arbitrary and minute classification of exercises and the arrangement of these in a "day's order" or lesson, as follows (Posse): (1) introductions, (2) archflexions, (3) heave movements, (4) balance movements, (5) shoulder blade movements, (6) abdominal exercises, (7) lateral trunk movements, (8) slow leg movements, (9) jumping and vaulting, (10) respiratory exercises. The idea of orderly progression in the use of exercises with regard to their physiological and mechanical difficulty is one of the most valuable contributions made to modern gymnastic practice. For instance, the effect upon circulation and respiration of exercise of the large muscular groups, as of the thigh and trunk, is much greater than of small groups, as of the arms or legs, and within reasonable limits this effect is intensified by overcoming resistance as in lifting the weight of the body in jumping or other precipitant exercises. Exercises for these muscular groups therefore bear a logical relation to one another. Muscular strength is similarly amenable to progressive development through the application of some of the laws of mechanics. For instance, work of the trunk muscles is increased by altering the leverage through positions of the arms, and balance exercises are made more difficult by narrowing the base and shifting the centre of gravity. The Swedish medical gymnastics, especially in orthopedic practice and in the form of massage, are widely used.

Physical training in the United States received its first popular impetus from Dr. Dio Lewis, about 1860. Dr. Lewis was not a scientific worker, but aiming to put the spirit of sport and play into gymnastics promulgated some good all-over exercise in free-hand move-

ments and with dumb-bells, wands, Indian clubs, bean bags and some apparatus of his own devising — the «shoulder pusher» and «iron crown.» This work had an extended vogue throughout the country with both men and women, and was introduced into many schools. Since the Civil War, and especially in the last 10 years of the 19th century and the early 20th century, physical training has undergone a steady advancement in the United States, both in the extent to which it is used, and in the development of the subject itself.

In 1870 and later Dr. Dudley A. Sargent invented a series of pulley weight machines, some 40 in number, which have since held a prominent place in gymnastic equipment. The best known of these is the chest weight machine. By means of these appliances exercise may be localized to given groups of muscles, thus developing weak or undeveloped parts of the body. Obviously measurement and general physical examination of pupils is an important factor in the thorough use of such a method.

In 1887–88 there swept over the country a popular fad for what was called the Delsarte system. François Delsarte (1811–71) was a native of France, whose work to establish laws of expression for the dramatic art probably led to the origination of certain forms of free-hand exercise, æsthetic in character, which have been developed by a number of American workers, though his daughter has expressly denied that he had anything to do with gymnastics. His work was approached entirely from a philosophical, as distinguished from a physiological, view point, and the mystic number three and its multiples governed the various modes of movement and expression. That every movement and attitude of the body should express an emotion was a cardinal point. The cause of physical training was for a time retarded by the sentimental, languid and unscientific atmosphere which surrounded much of this work, but with the passing of the vogue it is found to have left two distinct types of exercise and certain principles of graceful motion which have permanent value. To make the body flexible, and to free it from habits of muscular tension, relaxing (devitalizing) exercises are used. These consist in making absolutely limp one part of the body after another, and finally the whole at once, by removing all tension from the articulations. These exercises are followed by a series of energizing or vitalizing movements, slow and rhythmic. Principles of grace embodied in these include the slow evolution of movement from one point to the next, and the movement in opposition (opposite directions) of two parts moving simultaneously. Delsarte's expressional work is highly valued in dramatic training.

Swedish educational gymnastics were introduced into this country in 1888 by Baron Nils Posse, having been preceded many years by German gymnastics. These two schools or methods of work, differing radically, were each introduced with the handicap of the term «system,» implying fixed limits and arbitrary modes of procedure, as distinguished from flexible methods, capable of growth and adaptation, though each claimed the latter quality. A bitter rivalry ensued, extending over many years and hindering the development of the subject. This warring of systems has largely given place to a broader spirit which recognizes the fact that different methods of gymnastic procedure are fitted to produce different results suited to different conditions and temperaments. Certain principles have emerged which, in a more flexible guise than when first introduced to us, are more largely entering into all gymnastic work and may be said to serve as criteria of its quality. These principles include a careful consideration of the condition and needs of the individual, a purposeful selection of exercise with regard to its effects, a general, though not of necessity an uninterrupted, progression in its use, all-over body exercise in a given lesson, and its arrangement with reference to curves of effort — that is, the gradual approach to, and receding from, maximal heart effects. Awkward performance is giving way to the good form or finished execution that denotes definite training of the power of muscular co-ordination; cultivation of erect carriage and generally good posture are recognized as indispensable. Methods of teaching gymnastics are found to be as amenable to the laws of pedagogy as any other branch worthy to rank in the science of education, and recognition is given to the training or use of psychological powers — the motor sense, the will, objective and subjective interest, automatic and voluntary attention, etc. Indeed, physiological psychology and child study have contributed as much to physical training as has the physiological laboratory.

The professional training of teachers of gymnastics has done much to advance the cause of the subject which long suffered from the idea that agility of performance was a sufficient qualification for teaching. There are in the United States many normal schools of physical training, offering courses from two to four years in length, including several universities and colleges that give normal instruction in the theory and practice of the subject. In addition many normal schools for class teachers train their students to conduct class exercises in various branches of physical training. There are also each year many summer schools of physical training. The subjects studied in normal schools of physical training include physics, chemistry, histology, physiology, anatomy, kinesiology, anthropometry, biology, symptomology, psychology, pedagogy; personal, public and school hygiene, besides the various kinds of practice work in gymnastics, athletics, swimming and other sports, fencing, games, dancing, voice training and practice teaching.

The modern gymnasium requires expert knowledge for its design and construction. From 30 to 40 square feet of floor space should be allowed for each pupil exercising in a class. Trusses or ceiling beams should clear the floor 20 feet and a gallery for a running track should be 10 or 11 feet clear from the floor. Lockers, swimming tank, office and examining room for the director should be included.

Anthropometry, as used in connection with physical training, consists mainly of the measurement of significant girths with a steel tape; depths, as of chest and abdomen, with calipers; standing and sitting heights with the stadiometer; strength tests of the various muscular groups with dynamometers, etc.; the measurement of lung capacity with the spirometer and the taking of weight. The testing of sight and

hearing, and psychological tests for reaction, time, etc., are often included. To these are added examination of the heart, lungs, spine, etc., and a tabulation of facts of personal history bearing upon heredity and other significant influences. Such examination is made by the physical directors of practically all colleges and universities, secondary and normal schools and young men's Christian associations. From this data an individual may be compared with the mean, average or normal type for his age and height, exercise prescribed according to his needs and development noted from time to time. Physical examination of children in the public elementary schools is rapidly becoming an established feature, and many States have laws requiring such regular examinations and systematic physical training for children of school age. Out of this there is evolving a more scientific correlation between the laws of growth and physical exercise. These laws have been largely formulated on the classic studies first made by a commission in Sweden, and in the United States by Dr. W. T. Porter in Saint Louis and Dr. H. P. Bowditch in Boston. From these measurements have come a recognition of growth periods and laws of growth that form a valuable index to required exercise.

The representative organization of physical training in the United States is the American Physical Education Association (formerly The American Association for the Advancement of Physical Education), organized in 1885. The 'Proceedings' of this association and its official organ, '*The American Physical Educational Review*' published since 1896, form the most valuable depository in English of the scientific and philosophical material on the subject.

Other organizations of national scope should be mentioned, each of which is devoted to a special phase of physical development. Athletics and sports have been mainly fostered by the Amateur Athletic Union, the National Collegiate Athletic Association, The Intercollegiate Association of Amateur Athletes of America, The Young Men's Christian Association Athletic League and Public Schools Athletic Leagues for Boys and Girls. These athletic organizations govern amateur standards and awards, are more or less concerned with arrangements for competitive games and meets, furnish officials for these and are usually represented on the rules committees for various games. The Playground and Recreation Association of America, organized in 1904, has secured children's playgrounds for many communities throughout the country, and has furthered all kinds of recreation for children and adults, including leadership in war camp community service during the World War. This organization has been a large factor in wide recognition of play as a factor in social economics and for its educational values, physical, mental and moral. The American Posture League, founded in 1914, has done much practical work in gaining recognition of habitual body posture as a fundamental feature of sound physical development and health. Its educational work has included the promulgation of a standardized or "Triple Test" for posture that has furnished means of measuring educational results in this particular. The main work of the society, however, has been to improve the environment as it affects posture, by fashioning in correct anatomic form many articles of every-day use that mold the posture of the body — a scientific work engaging in the league's technical committees, orthopœdic surgeons, school hygienists, etc., and resulting in the standardization of school and other furniture, shoes, corsets, waists, coats, hose supporters and other articles. The Life Extension Institute, founded in 1915, is also unique as an organization in the field of public health and preventive medicine. It undertakes, by standardized periodic examinations, to discover incipient or developed pathological conditions and so forestall illness. These examinations are made by contract with industrial organizations for their employees, or for individuals on annual membership or otherwise. In the examination of many thousands of industrial and office workers the Life Extension Institute has found that from 50 per cent to 59 per cent have impairments of arteries, kidneys, heart or other organs that indicate breakdown if not taken promptly in hand and remedied. The army draft, with its rejection of 40 per cent on grounds of physical defects, and the Marine Corps rejection of 90 per cent startled the country into realization of the need for better physical development for children, better living and working conditions for adults and better personal hygiene for all.

At present there are in the United States of America about 60 societies engaged in public health work. Almost one-half of these are devoted to such work exclusively and the others supplement their main work of social or educational betterment with some activity in preventive medicine. Among the many other indications of a vast movement among the more intelligent public to improve health and development and forestall illness may be mentioned the great health engineering work of the Rockefeller Foundation through its medical board, of the Russell Sage Foundation, enormous private bequests to medical research, the improvement of health conditions and the wiping out of specific diseases in whole districts, as in New Orleans, Cuba and the Panama Canal Zone. Much of this has been the work of the Federal government through the surgeon-general's office and its other agencies (segregated in 1918 under the United States Public Health Service). The community surveys and cooperative work of all health agencies in the great experimental studies in Framingham, Mass., Jackson, Mich., and Cincinnati, Ohio; the anti-tuberculosis crusade; the attention to school and industrial luncheons; the attention to nutrition, food values and wholesome food for the masses preceding, during and after the war — these are all parts of the great movement for improved health standards.

All of these health agencies recognize physical exercise as a fundamental requisite to any health program. Conversely, systematic work in physical exercise, to produce its best results, should be related to other health considerations and preceded by thorough physical examination. It has been estimated (New York City Department of Health) that out of any 1,000 industrial workers 25 are all the time absent for illness. The United States Health Service has estimated the annual economic loss from illness among industrial workers in this

country at $750,000,000. The future of the nation in its economic power and in the strength and character of its population, is thus inherent in this subject of physical development.

JESSIE H. BANCROFT,
Assistant Director, Physical Training, Public Schools, New York City.

PHYSICIAN, one who practises or is skilled in the art of healing and in methods of preserving and promoting health, especially one who prescribes remedies for diseases; specifically, one who is legally authorized to practise medicine. In the United States physicians qualify by compliance with State requirements. State examinations for ascertaining the fitness of candidates for this calling are now generally held, and to those who successfully pass them license to practise is granted. Usually a physician is not bound to attend every person who may call him; but having undertaken to treat a patient, he is liable to the penalties of malpractice in case of injury resulting from his own incompetence or neglect. As between physician and patient, relations are privileged and confidential, and a patient's secrets in the keeping of a physician are inviolable, the State not even requiring them to be made known in legal procedures. The relations of physicians to the legal fraternity and to the legal transactions of the State form part of the subject of medical jurisprudence (q.v.). Consult: Cabot, R. C., 'Training and Rewards of the Physician' (Philadelphia 1918); Cathell, D. W., 'Book on the Physician Himself' (Baltimore 1922); Collins, J., 'A Doctor Looks at Doctors' (New York 1927); Hale-White, W., 'Great Doctors of the 19th Century' (Baltimore 1935); Warbasse, J. P., 'Doctor and the Public' (New York 1935); Wolf, G. D., 'Physician's Business.'

PHYSICIANS, Royal College of, Edinburgh, incorporated 26 Nov. 1681 by royal charter; a body empowered to make laws for promoting and regulating the practice of medicine within the city of Edinburgh, town of Leith, and districts of the Canongate, West Port, Pleasance and Potterrow. No person was to be allowed to practise medicine within these limits without a license or diploma from the college, and all medicines sold within the same limits were made liable to be inspected by the officers of the college, together with a magistrate and chemist, who were authorized to destroy all medicines which were found bad or unwholesome. No apothecary was allowed to open a shop until he had passed an examination before the president and censors of the college. Its Fellows were freed from jury duty. Many of the rights and practices of the college gradually fell into abeyance, due to the changes in customs brought about as time passed. A warrant from the college is no longer necessary to a practitioner; but the body is now represented in the general medical council established by the Medical Act of 1858. A new charter was granted to the college by Queen Victoria on 16 Aug. 1861, under which the institution operates at the present time. In connection with the college there is a library, founded in 1683, and a museum of materia medica, begun in 1835. The college, since 1846, is located in its own building in Queen street. Consult 'Historical Sketch and Laws of the Royal College of Physicians of Edinburgh, 1681–1882' (Edinburgh 1882).

PHYSICIANS, Royal College of, London, a body whose organization dates from 1518. In that year Thomas Linacre, the celebrated scholar and humanist, one of the physicians of Henry VIII, obtained from him, with the aid of Cardinal Wolsey, letters patent dated 23 Sept. 1518 and incorporating all men of the medical faculty in London as one body. Various privileges were accorded to them, chiefly that of prohibiting any one from practising as a physician in London, or within seven miles of it, unless he had first obtained a license from this corporation. A charter granted four years later confirmed the privileges of the body, except that graduates of Oxford and Cambridge were permitted to practise within the jurisdiction of the college without previously being examined by it. Various charters have been since granted to the college, but from the passing of the Medical Act of 1858 its license has not been necessary to those practising in London or within seven miles around. At present the corporation consists of a president, fellows and members. It occupies a building in Pall Mall East, opened in 1825. Consult Garth, Sir S., 'The Dispensary, a Poem' (London n. d.); Munk, W., 'The Roll of the Royal College of Physicians of London, 1518–1825' (3 vols., London 1878).

PHYSICIANS' LIABILITY INSURANCE. See ACCIDENT INSURANCE.

PHYSICK, fiz'ik, **Philip Syng,** American surgeon: b. Philadelphia, 7 July 1768; d. there, 15 Dec. 1837. His father, Edmund Physick, was an Englishman and, previous to the outbreak of the revolution, Keeper of the Great Seal of Pennsylvania. Philip Syng Physick was graduated from the College of the University of Pennsylvania in 1785, studied medicine under Dr. Adam Kuhn, a well-known Philadelphia practitioner and pupil of Linnæus and at the University of Pennsylvania. In 1789 he accompanied his father to England where he continued his medical studies under Drs. Hunter, Clark and Osborne. In January 1790 he was appointed for one year to the position of house surgeon at Saint George's Hospital, London. In January 1791, at the expiration of his term at the hospital, he received his diploma from the Royal College of Surgeons in London. Shortly after that he went to Edinburgh where he continued his medical studies until May 1792 when he received the degree of M.D. from the University of Edinburgh. He returned to Philadelphia in 1792 and began practice. In

1793 he did valuable service during a severe epidemic of yellow fever as the physician of a special hospital established by the board of health. He himself suffered a severe attack, but recovered. His fame as a highly skilled and successful surgeon spread rapidly. As early as 1794 he was elected one of the surgeons of the Pennsylvania Hospital, Philadelphia, where he performed many hitherto more or less unknown operations. During his career he also developed a number of surgical instruments to such a point of perfection that some of them are still used to-day in accordance with his plans. During the repeated yellow fever epidemics of 1797, 1798 and 1799, he was again so active that he suffered a second attack from which he recovered only after a severe illness. In 1805 he was appointed professor of surgery at the University of Pennsylvania and in 1819 became professor of anatomy there, which post he held till 1831. In 1824 he was elected president of the Philadelphia Medical Society, continuing as such until his death. In 1825 he was made a member of the Royal Academy of Medicine of France and in 1836 an honorary fellow of the Royal Medical and Chirurgical Society of London. He has been styled «the father of American Surgery.» Consult Bell, John, 'Philip Syng Physick' (in 'Lives of Eminent American Physicians and Surgeons' ed. by Gross, S. D., Philadelphia 1861); Randolph, J., 'A Memoir on the Life and Character of Philip Syng Physick' (Philadelphia 1839).

PHYSICS may be defined as the science of *energy,* of the transformations of energy, and of its relation to *matter* (q.v.). This is an imperfect definition in that, first, a comprehensive understanding of the meaning of *energy* involves a complete knowledge of physics; and second, the science of energy, in its broadest sense, comprehends all science, while the content of physics is generally limited to the scope of the topics which will be outlined below. Indeed, in its earlier history and under its early title of «natural philosophy,» physics did encompass a much wider scope; but by a process of exclusion of certain branches as they developed into specialized sciences, such as chemistry, astronomy, metallurgy, meteorology and geology, it has been limited to its present scope; and about 1870 its present name of physics took the place of the older title. This process of separation is still going on: as, for example, certain parts of electricity, that have heretofore belonged to physics, are gradually being developed into the separate science of *electronics* (q.v.), as distinguished from the practice of electrical engineering. At the same time, investigation and discovery are adding new fields to the science of physics. In its applications and its interrelationships, physics lies at the foundation of *all* of the experimental sciences and still assists their modern development, to a lesser extent only than does mathematics. Thus the interconnections between physics and the other sciences, particularly chemistry, are so intimate that it is impossible to draw an exact line of separation, so that in these borderlands between the sciences have been built up new sciences which partake of the nature of both and which have consequently been named physical chemistry, meteorological physics, physical astronomy or astrophysics, biophysics, etc.

Modern physics is an inductive science. Like the other sciences, it is based upon a belief in the «constancy of nature»; upon the belief that the same cause, operating under the same conditions, will result in the same effects at any time. In order to ascertain the causal relations of physical occurrences, or phenomena, observations are made of what conditions seem to affect the phenomenon under study, and experiments are performed in which the conditions are under the control of the observer, so that they may be varied separately, in order to determine which conditions are essential and which are accidental. Then exact measurements are made to determine the quantitative relation between the essential conditions and the effect resulting. This quantitative relation, rigidly established by exhaustive experiments and with its limitations clearly specified, is known as a physical *law.* For example, it is found that for a constant mass of gas, at a constant temperature, the product of its pressure by its corresponding volume is a constant for most gases within a moderate range of pressures; and this relation is known as Boyle's Law (q.v.). It may be called an empirical law, in that it represents a relationship between two physical quantities, the explanation of which it does not give. A study of many similar or related phenomena suggests a generalization or *hypothesis* as the explanation of them all. This hypothesis, tested, modified and perfected by extensive study and experimentation along lines suggested by it and extending to all known phenomena to which it may have any relation, and strengthened by its use in suggesting and predicting new phenomena, becomes a physical *theory* and may later attain to the dignity of a general physical law. Thus a further study of the relations between the pressure and volume of a gas and the other factors affecting its behavior led to the kinetic hypothesis of gases and this hypothesis, suitably modified, having been found to be in agreement with the phenomena it was called upon to explain and to be still further supported by other phenomena (such as, for example, the Brownian movements, q.v.), has become the kinetic or dynamic theory of gases.

Physics, as the science of energy, has its unification in the principle of the conservation of energy. The statement of this, in the words of Maxwell, is: «The total energy of any material system is a quantity which can neither be increased nor diminished by any action between the parts of the system, though it may be transformed into any of the forms of which energy is susceptible.» The importance of this principle and its influence in unifying and in developing physics cannot be overestimated. Just as the development of the principle of conservation of matter unified chemistry and put into the hands of the chemist a rule for measuring his facts and for checking his theories, so the principle of conservation of energy has become the basic law connecting all physical phenomena, for testing the accuracy of physical experiments, and for checking, modifying and extending physical theory. Obviously, a great deal depends upon our definition of energy, and the great importance of the conservation principle lies in the fact that there is so simply definable a physical function as mechanical energy which does remain invariant in a «closed» system;

and furthermore, that it is possible to express quantitatively all other physical manifestations of nature in terms of this invariant energy function.

That it has now been shown that energy and matter are interchangeable does not necessarily mean that the foundation of physics, the law of conservation of energy, and that of chemistry, the law of conservation of matter, must be discarded. It is true that energy can disappear from a system to reappear as matter and the reverse. This leaves us with a law of «conservation of energy and matter.» The conditions under which such a change takes place, however, are such that this phenomenon can generally be disregarded in all ordinary work in physics and chemistry. It is important only when dealing with the behavior of particles of extremely high speed and consequent reactions, and under astronomical conditions.

In the paragraphs which follow, attempt is made to outline the content of physics as it exists at the present writing. It should be emphasized again that this content cannot be fixed for all time; that it is changing, undergoing development, essentially dynamic in its nature. It is at present generally divided into the following topics, or similar ones: mechanics and mechanical properties of matter (*pure* and *physical* mechanics), sound, heat, light, and magnetism and electricity. This division is to a great extent arbitrary, made for convenience in study, and the modern science is careful to recognize it as such and to recognize the unity of relationship among all its parts.

Mechanics.—Mechanics (or pure mechanics) is essentially a branch of mathematics, based on certain axioms derived from physics, but its basic importance in all branches of physical science makes it one of the first topics included in a study of physics. It is that branch of science which deals with motion, with forces, with matter in so far as it is affected by motion and forces, i.e., mass and configuration, and with their interrelations. It is generally divided into kinematics, which deals with motion by itself; and dynamics, of which statics deals with forces alone, under conditions of balance, or equilibrium, and kinetics deals with matter in motion, as the result of the action of forces, and with forces as producing motion. Hydrostatics and hydraulics should be mentioned as important branches or extensions of this part of the science, although often included in the next topic. (See DYNAMICS; HYDRAULICS; HYDROSTATICS; KINEMATICS.)

Properties of matter (physical mechanics) comprises the general mechanical properties of matter in each of its three physical states—solid, liquid and gaseous, and the laws that express the causal relations found to exist among them. It includes also all of the distinctive data and physical constants obtained by experimentation with different kinds of material. Density, gravitation, buoyancy, gas laws, elasticity, viscosity, diffusion, osmosis, and surface tension are some of the important subtopics of this subject. Other divisions of the subject are often made, in order to present some particular phase or viewpoint: for example, division into *mass* mechanics and *molecular* mechanics. See MECHANICS.

Wave Motion.—Although wave motion is, in its mathematical development, properly a branch of pure mechanics, it is generally included with, or placed just before, the subject of sound, since in sound waves and in the vibrations of sounding bodies (stretched strings, rods, bells, and air columns), there exist the most perfect and tangible examples of such motion. Wave mechanics, because of its recently acquired importance in the study of atomic structure, is rapidly becoming a highly specialized branch of knowledge on its own account, however. See WAVE AND WAVE-MOTION.

Sound.—Aside from a study of the physical characteristics of audible sounds, particularly musical sounds and their physical relations in the musical scale and in musical composition, and quite recently, vowel sounds and other sounds occurring in articulate speech, the study of sound is the study of a typical wave motion, whose characteristics (reflection, refraction, interference, etc.), may be easily demonstrated on a convenient scale. The practical importance of the applications of the physics of sound, in the design of sound-producing and reproducing instruments, and in the design of auditoriums and similar public halls, has attained to considerable recognition and emphasis in recent years. This has resulted in producing a new profession, that of acoustical engineering, which finds its field of usefulness largely in radio and talking pictures. (See ACOUSTICS.)

Descriptions of the mode of production of vocal sounds, and of the mechanism of audition, is usually included in a general treatise on physics, although they now more properly belong to the respective domains of physiology and of the new experimental psychology.

Heat.—The subtopics of heat, given in the usual order, are thermometry, thermal expansion, calorimetry, change of state, transference of heat and thermodynamics. Thermometry covers the usual empiric methods of temperature measurement; the idea of the Kelvin or thermodynamic (absolute) temperature scale is left to the proper section of thermodynamics. Thermal expansion includes the experimental determination of the empirical relations existing between physical dimension and temperature for different materials, and the principles and constants thus determined are of considerable importance to the design of all kinds of machinery and construction, and are of vital importance in physical mensuration and chronometry.

Calorimetry and changes of state deal with measurments of quantities of heat. Although arbitrary units of heat quantity (calory, British thermal unit, etc.), are most frequently used, the establishment by Joule and others of the exact equivalence between heat quantity and mechanical energy has made the use of energy units (erg, joule, etc.), increasingly more common. The experimental work consists largely in the determination of specific heats (latent), heats of changes of state (fusion, vaporization, etc.), and of solution, combustion, etc.; and in the study of the physical phenomena which accompany change of state, such as change of volume, of specific heat, of color, etc., and of the effects of all the possible external factors which may affect or change the conditions of change of state. The value of these physical quantities and relationship for the pure elements and for their compounds has assumed such importance in chemical theory and practice that their determination has become an important part of the borderland science, physical chem-

istry. The study of change of state has made valuable use of thermodynamic reasoning, and among the important developments resulting in recent years should be mentioned the obtainment of nearly all of the normally gaseous elements and compounds in liquid form, and in many cases in solid form and the production of extremely low temperatures by their means. Transfer of heat may be accomplished by three different methods—conduction, convection, and radiation: the first two methods depend for their operation upon intervening material media and are properly a transfer of heat energy as such; while the third is a type of electromagnetic radiation, and is more completely treated under that heading.

Thermodynamics, as the name implies, is involved whenever there is a transfer into heat energy of any other form of energy, or vice versa; and for the investigation and study of such phenomena there have been developed certain general relationships, theorems and methods of treatment, which, taken together in their proper arrangement, form a peculiar and distinct mathematical branch of science which we may designate as *formal* thermodynamics, to distinguish it from the broader field of general thermodynamics. The applications of this thermodynamic reasoning are found in every branch of physical and chemical theory, including electrical, electrochemical and radiation theory.

The best-known of the relationships of formal thermodynamics are the Carnot theorem and the Kelvin or thermodynamic temperature scale. The latter furnishes a temperature standard which is independent of the physical properties of any physical substance, while the two together not only furnish a criterion for the efficient performance of any heat engine (steam, gas, etc.), the purpose for which they were originally developed, but are also the basis of relationships connecting the factors involved in change of state (e.g., the Clapeyron-Clausius equation), thermoelectricity, solution, and innumerable other physical and physicochemical phenomena. Certain special thermodynamic functions such as entropy, which is the common one, have been formulated to simplify the mathematical treatment of these problems. General thermodynamics includes, in addition to the reasoning of formal thermodynamics and the applications mentioned above, a thorough study of the relations connecting the mechanical and thermal conditions of matter in the different states, and in the transition states: such as, for example, the relation of pressure and specific volume to the temperature, specific heats and heat of transformation, and their interpretation according to thermodynamic reasoning. The idea of a «perfect» gas, and the evolution of the kinetic or dynamic (molecular) theory of gases, are logical developments of this section of physics. In recent years the methods of *statistical* mechanics which have been developed for the study of certain types of thermodynamic problems have met with considerable success in the study of the dynamic theory and of radiation theory. The many applications of thermodynamic theory and reasoning in heat-power engineering, physical chemistry and other fields, might properly be classed as applied or technical thermodynamics. See Gases, Kinetic Theory of; Heat; Thermodynamics.

Light.—Light is a form of radiant energy capable of stimulating the nerve termini of the retina of the human eye. Two well-defined methods of study are generally recognized. To a limited extent, its phenomena may be studied, and simple laws for its reflection and refraction by mirrors, prisms and lenses be deduced, without reference to the physical nature of light energy, or of its propagation. This is the method of geometrical optics, as distinguished from physical optics; and it suffices for the design of apparatus such as cameras, telescopes, surveying instruments, and range finders, and for most of the work of perfecting the optical surfaces of the lenses used in such instruments (to make them achromatic, anastigmatic, and aplanatic), although intelligent work in this field is now guided by a knowledge of many of the phenomena which come within the scope of physical optics. In physical optics, the phenomena of light are studied for the purpose of determining the nature of light energy and of its propagation, and of its relation to other forms of energy. Lately this has extended to the study of the nature of the bodies that produce light, and as well, of those that reflect, refract, or otherwise modify its character or propagation. Study of the phenomena of interference, of diffraction, of transmission in finite time, and of polarization, established the theory (the wave theory) that light energy is propagated through space as a transverse wave motion at a finite, though incredibly high, velocity. Spectral color is identified with wave length. Later investigations have identified light radiation as that part of electromagnetic radiation the wave lengths of which are capable of exciting the visual sense. The wave theory of light gives a clear and logical explanation of all of the phenomena of reflection and refraction, and in addition, has disclosed physical limitations to the clearness of the optical images produced thereby, other than the limitations to the perfection of the optical surfaces, the knowledge of which has done much toward the perfection of such optical instruments. Furthermore, the development of apparatus for the demonstration and study of the phenomena peculiar to physical optics has resulted in the invention of many new and valuable physical instruments—interferometers, diffraction gratings, and polarimeters—which open up new fields of knowledge and study, and permit of the measurement of many physical quantities, both new and old, to a previously unheard-of degree of accuracy.

The failure of the wave theory of light to explain the photoelectric effect and some other important phenomena stimulated the development of the *quantum theory* (q.v.) during the present century. According to this theory light consists of quanta or bundles of energy, now called photons, which are shot through space. These two theories appeared for many years to be wholly irreconcilable, and until recently that theory was used which seemed best to fit the case in question. It is now believed, however, that both are true, and that with every particle there is associated a wave, the wave becoming more prominent as the size of the particle is less. The existence of such a wave has been experimentally proved in the case of particles as large as the electron. In the case of very short waves, X-rays for example, the quantum nature of radiation predominates, and

this theory is commonly used to explain short wave phenomena. In the case of long waves, as in radio broadcasting, the wave predominates, and here the wave theory is used for explanatory purposes.

The study of the spectrum has proved a most fruitful field of endeavor: to the physicist, intent on knowing the structure of the molecule and the atom, it has suggested some of his best ideas; while to the chemist is given the ability to identify the minutest quantities of elements, by examination of emission, transmission (absorption), and reflection spectra; and to the astronomer starlight has revealed, in its spectrum, the composition, and sometimes the motion, of its celestial source. Photometry, the measurement of the brightness of luminous sources and of illuminated surfaces (illuminometry), is a branch of the applied science, developed by the physicist and psychologist in close co-operation, which is of great importance to the physical investigator, as well as to the illuminating engineer. See LIGHT; PHOTOMETRY; POLARIZATION; POLAROID LIGHT CONTROLS.

Electricity and Magnetism.—Nowadays electricity and magnetism are treated as a single subject, although in its earlier stages of development, different types of electric and magnetic phenomena were studied as magnetism, static electricity (eclectrostatics), and current electricity (electrokinetics), and it was only after considerable later work that the close relationship between them was recognized, as manifestations of the same form of energy. The division is still made for convenience in many treatises, particularly by those who favor the historical method. Magnetism covers the properties of permanent magnets, and the phenomena of magnetic fields produced by such magnets. Many of the problems of terrestrial magnetism may be considered on the assumption that the earth is a huge magnet, without regard to its source of magnetization, and most of the methods of magnetic survey have been developed under this heading. The magnetic properties of paramagnetic and diamagnetic substances (permeability, hysteresis, etc.) may be considered here, but are more generally included as a part of electrokinetics, under the subtopic of electromagnetism. The *molecular* (Ewing's) *theory* (q.v.) of magnetism is here used to explain the facts, although its complete development also properly belongs to the later section.

The quantity factor of electrical energy is electric charge; the intensity factor is electric potential difference. The presence of electric potential difference across a nonconductor (dielectric) produces what is often described as a piling up on the opposite boundaries of the dielectric of equal and opposite quantities of electric charge. The presence of electric potential difference across a conductor produces a continuous displacement or «flow» of electric charge across the conductor which constitutes an electric current, and which is accompanied by a field of magnetic force in the conductor and in the surrounding space. Study of the phenomena of the electrostatic field constitutes electrostatics, while that of the phenomena accompanying electric flow or current constitutes electrokinetics. The latter topic has proven up to this time far the more important, although the modern physics, both in theory and in practice, has been forced more and more to consider the electrostatic phenomena which accompany current flow; as for example, in electromagnetic radiation theory and its applications in wireless communication, in the theory and the applications of gaseous conduction, and in the design and operation of long distance, high potential transmission lines.

Electrical energy becomes manifest to our senses only indirectly, as it is transformed into other forms of energy, such as heat energy, chemical energy, and mechanical energy; the last most often through the intermediary of electromagnetic force action. The methods of measurement and of utilization of electrical energy are indirect, measuring and utilizing the transformed energy. On the other hand, electrical energy is produced by the transformation of the other forms of energy into electrical energy, and the commercial utilization of electricity became practicable only after the invention of dynamo-electric machinery, which made possible the efficient transformation of mechanical energy into electrical energy; the other methods of production being too limited and costly. Too numerous to mention are the inventions and practical applications of electricity to the needs of humanity: in communication, from the earliest telephone and the first Atlantic cable to the wireless telegraph and telephone of today and tomorrow; in illumination, where electricity has revolutionized the world's lighting methods; in power transmission, which has made possible the utilization of the least accessible of the world's power resources; in power application, from the largest motors to the smallest motors for fans and toys; in chemical production—the whole development of electrochemistry; in medicine, as in the applications of X-rays; and in literally millions of other ways, in every conceivable field, electricity is serving humanity. The development of the production, transmission and utilization of electric power constitutes the business of the electrical engineer. A complete outline of this quite modern, but already very extensive subject, with its relations to electrochemistry (q.v.) and electrical engineering, will be found elsewhere in these volumes. The most recent developments of electrical science in the way of advancement of knowledge of the nature of electricity itself are so epochal, so extended and so far-reaching in their bearing on all other physical theory, that their consideration is properly left to the paragraphs that follow. See ELECTRICITY; ELECTROMAGNETISM; MAGNETISM.

Recent Developments.—Although developments of major importance have been made in all fields of the science, yet certain lines of investigation have extended so far, and have established such profound unifying principles, as to justify their recognition as new sections of physical science. One of these is electromagnetic radiation. Maxwell's mathematical theories of electricity indicated the possibility of the propagation of energy through space as electromagnetic wave motion, a possibility that was experimentally verified by Hertz. The velocity of these «Hertzian» waves, which have since been applied with such great success to «wireless» communication, was found to be the same as the velocity of light: and from this followed directly the recognition of the identity of light radiation, of heat radiation, and of those regions of radiation of frequencies above and below

those corresponding to visible light, respectively called ultraviolet and infrared light or radiation, as all one and the same type of radiation, differing only in frequency and in methods of detection; while the discovery of X-radiation (and gamma-radiation of radioactive materials) has extended our knowledge of electromagnetic radiation to what seems to be the extreme upper end of the frequency scale. The importance of this unifying principle to the comprehension of light phenomena can only be suggested here; the study of light is now the study of electromagnetic radiation; and theories advanced to explain its phenomena may be tested, not only throughout the little more than an octave of frequencies comprised by the visible spectrum, or even the much greater range available when the ultraviolet and infrared regions are included, but throughout the innumerable octaves included between the longest «wireless» rays and the shortest gamma rays. Big unexplored intermediate gaps still exist in the «spectrum» of radiant electrical energy, due to the lack of suitable detectors or of known radiators for those regions, which leave ample opportunity for future investigation. In this field of study belong also the phenomena of fluorescence and phosphorescence, which, together with those of the «characteristic» X-radiation, form a fascinating field of complex radiation phenomena, which seem to hold many of the secrets of the structure of matter. On the theoretical side, mathematical theories to account for the phenomena of thermal radiation have been developed by Stephen, W. Wien, Max Planck and others, and the quantum theory, first advanced by Planck, and later modified by himself and others, has aroused widespread interest both on account of its revolutionary suggestions, and because of its wide application and remarkable agreement with many experimental facts. As already pointed out, the wave and quantum theories have now been reconciled.

Another field of investigation is that which began with the study of electric discharge through rarified gases, and which has reached its present culmination in the modern *electron theory* (q.v.) of electricity. On the practical side, the toy of the scientist, the «vacuum» tube, has proved the progenitor of the X-ray tube, the vacuum tube so essential to «wireless» and television apparatus, the thermionic rectifier, and many other valuable devices. The work of J. J. Thomson, C. T. R. Wilson, Robert Millikan, and others has shown that the *electrons* or carriers of negative electricity in the vacuum tube discharge, are invariably associated with a fixed amount of charge; and that this charge, whose value has been determined with great accuracy, is the *elementary* electric charge, of which all other charges are exact multiples. And this conception of electric charge, together with James Maxwell's theory of electric fields, provides a rational basis for the study of all of the electrical phenomena of conduction, thermoelectricity and the like, as well as of the phenomena whose existence has been revealed to us through this theory, such as thermionic currents, photoelectricity, and ionization in gases.

Still another field of both theoretical and experimental development is that in which attempts have been made to develop theories of the structure of matter. The discoveries in radioactivity, disclosing as they have the existence of atomic disintegration, reveal a new complexity of atomic structure and at the same time suggest a simplicity of atomic constituents, which, together with the knowledge already gained by the observation of the behavior of electrons in vacuum tube discharge, has stimulated many serious attempts to build up an electric atom, consisting of some form of positively charged nucleus about whose center electrons circle or vibrate at very high frequencies. As is to be expected, only very partial success has been obtained in devising such an atom that will be in accord with all of the known atomic phenomena, such as the phenomena of radiation and of electricity, and which will at the same time have all of the necessary chemical properties.

The present trend is away from any attempt to visualize an atom which can be constructed as a mechanical model and to consider it entirely as an abstract mathematical deduction. With the wave equation as a foundation, it is possible to build up equations which predict the behavior of atoms while neglecting any consideration of the mechanism by which these atomic phenomena are brought about. This may seem like an unjustifiable procedure unless one realizes that it has been accepted for years in the case of many other phenomena. No attempt is made to explain as commonplace a thing as gravity, although by means of equations we can predict gravitational behavior with great accuracy.

No one can prophesy the future of this class of investigation. In another direction, the discovery that X-ray wave lengths are comparable with the distances between the atoms in a crystal has enabled Sir William Bragg and others to study the structure of crystals, and not only to verify the regular arrangement of the atoms, which had been guessed at previously, but to determine the exact positions and spacing of the atoms in a great many simple crystals: a work which is gradually extending to the analysis of more and more complex crystals.

At the present time the center of interest for physicists is the bombardment of atoms by means of high speed particles. Such particles may be obtained by means of high voltage generators, by the cyclotron (see Atom-Smashers) and other similar devices, and by products of other atomic disintegrations. Such experiments have yielded much information concerning the structure of matter and have made transmutation of the elements, the dream of alchemists of the early ages, a reality. As yet, however, transmutations on a commercial scale are not possible. One would be rash to prophesy either that they will or will not ultimately become so. Of particular interest in this field is the behavior of uranium which, when bombarded with relatively slow speed neutrons, will emit disintegration products having tremendous energy in comparison to the energy received from the neutron. Concerned in this reaction is the uranium isotope 235 and when this can be obtained in reasonably pure form in sufficient amounts atomic power will have become practical. The most eminent scientists of today are hopefully at work on this problem and it seems not unreasonable to expect that they may succeed. Its possibilities confound the imagination.

One can perhaps conclude this section in no better way than to point out the all inclusiveness of the study of physics as shown by the

fact that the theory of relativity, developed so ably by Einstein, finds its greatest application in the study of the infinitely small particles which constitute the atom, and on the other hand in astronomical problems where distances are measured in millions or billions of light years. See ATOMIC THEORY; RADIATION; RADIOACTIVITY; URANIUM; X-RAY.

Historical.—The history of science, properly written, is more interesting than the history of wars and empires; for it tells the story of the development of human ideas. Yet in spite of this, very few histories of science are to be found. Only a brief outline of the history of physics may be given here; and, aside from the few references given in the bibliography below, further knowledge of the history of physics must be gleaned from the biographies and writings of the men whose names are famous for their scientific achievements. Physics, in common with the other sciences, may trace its origins to remotest antiquity; but its modern development, which began with its recognition as an experimental science, dates from about the 16th century. Although the knowledge of the ancients of civilization—the Greeks, Romans, Egyptians, and Arabians—comprised many isolated scientific discoveries and inventions, and while the writings of their philosophers often turned toward the explanation of them, yet it cannot be said that the ancients made any appreciable contributions toward the advancement of science; certainly none comparable with their contributions to other fields of thought. While it can be said that the authority of their master philosophers, such as Aristotle, stood a formidable barrier to scientific advancement for centuries, the confused and intimate relations between scientific, metaphysical and mystical ideas, combined with an inexplicable disregard of experiment as a means of interpretation of nature, opposed any real advancement. The achievements of Archimedes in the fields of statics and hydrostatics stand among the few solitary exceptions that foreshadow the modern scientific viewpoint.

During the Middle Ages much of the scientific knowledge of the ancients was irretrievably lost, and most of that which survived lay dormant. The supreme authority of Aristotle among the scholastics, and their syllogistic methods of reasoning, prevented any advancement of physical science by them. Only the alchemists, whose secret work must have discovered (and lost) many a scientific truth, and a few inspired men among the scholastics, such as Roger Bacon, kept alive the spark of progress that burst into flame in the later Italian Renaissance with the work of Galileo Galilei. Galileo's experimental studies of the motion of falling bodies are the first of their kind, and may truly be said to date the beginning of modern science, although the studies in magnetism of his contemporary, William Gilbert, are scarcely less epochal. From then on the opposition and persecution, which had so hindered progress on the part of Galileo and his predecessors, weakened and finally broke down, and the development of the new science progressed rapidly. The history of the science can for a while now be outlined by mentioning great names. Torricelli, Pascal, von Guericke, and later Boyle, Mariotte, and others discovered in quick succession the properties of the atmosphere and of gases and extended and unified the knowledge of hydrostatics. Huygens laid the foundations of physical optics, although building on them was deferred until nearly a century later. The list culminates in the name of Newton, who, born in the year that Galileo died, built upon the work of Galileo, and gave us our complete system of mechanics in his 'Principia,' published in 1686–87. His experimental investigations in light added greatly to the knowledge of that subject, although here he was unfortunate in his theoretical reasoning.

During a period which includes the 18th century and the early part of the 19th century, the spread of popular interest in experimental science, already noted in the foundation of the Royal Society of London in 1662, of the Académie des Sciences at Paris in 1666, and of the corresponding society at Berlin in 1700, stimulated scientific effort to an extent which made this period pre-eminently one of scientific discovery. The names of Franklin, Cavendish, Black, Young, Fresnel, Galvani, Volta, Ohm, Ampère, Gauss, Davy, and Faraday represent only a part of those whose brilliant discoveries and clear thinking brought about such rapid advances in all branches of physics. Some of these, such as Franklin, Cavendish, Black, and Davy, are to be recognized as men also prominent in other and now far separated activities. This versatility is better understood when it is remembered that it was only after the discoveries of this period had added so much to the knowledge of natural philosophy, as all of physical science was then called, that its differentiation into specialized sciences—physics, chemistry, etc.—began; and that, even after chemistry obtained individual recognition, physics formed the major portion of what remained, and was known as natural philosophy for considerable time thereafter. The industrial revolution in England about 1770, brought about as it was by scientific discoveries such as those which resulted in the invention of Watt's steam engine, had a profound reaction on scientific discovery in the 19th century.

The discovery of electromagnetic induction by Faraday (q.v.) in 1831 made possible the invention of the dynamo, whose commercial importance was at once recognized, and developments of commercial applications of electrical energy took place with great rapidity. In another direction a new tendency is to be noted in the establishment, during the first half of the 19th century, under the leadership of Helmholtz, Mayer, Rumford, and Joule of the principle of conservation of energy and of its universal application. William Thomson (Lord Kelvin) was an important participator in this work, which he carried further by applying the principle to the co-ordination and extension of the theory of thermodynamics which had been so ably begun by Carnot and his contemporaries.

These two points of departure along new and divergent lines of development, between which experimental investigation continued to flourish, mark the beginning of the modern period of science. The history of the commercial side is initiated by a remarkable series of brilliant inventions such as the telegraph, telephone, transatlantic cable, incandescent lamp, electric traction, etc.; and its later details belong to electrical engineering. On the purely scientific side, development has been no less rapid, though

until recently, less spectacular. Maxwell's genius early shaped the course of all later theoretical reasoning in electricity and light, while Kelvin developed much of the apparatus now used in electrical measurements. Joule, Amagat, Andrews, and others continued the experimental studies begun by Charles and Regnault of the properties of gases, where later a spectacular result was realized in the liquefaction of air and other gases.

The history of the later developments of this period has been touched upon in a previous section. Few discoveries stand out in their entirety as do the discoveries of X-rays by Roentgen in 1896, of radioactivity by Becquerel the same year, or of radium by the Curies in 1898. The developments have been so varied, and much of the advancement has been by a process of growth through the combined efforts of so many men, that it must be left to the historian of 100 years hence to look back over this period and properly to adjudge its achievements.

Bibliography.—No attempt is here made to even begin to give a complete bibliography of the science. This would be impracticable. The lists following contain titles of a fairly representative few of the recent and more important publications in the English language.

HISTORICAL: Einstein and Infeld, 'Evolution of Physics' (New York 1938); Cajori, F., 'A History of Physics in its Elementary Branches' (New York 1929); Crew, H., 'The Rise of Modern Physics' (2d ed. 1935); Darrow, F. L., 'The New World of Physical Discovery' (Indianapolis 1932); Hart, I. B., 'Makers of Science' (London 1923); Heyl, P. R., 'The Fundamental Conception of Physics in the Light of Modern Discovery' (Baltimore 1926); Millikan, R. A., 'Evolution in Science and Religion' (New Haven 1927); Whetham, W. C. D., 'The Recent Development of Physical Science' (London 1924).

GENERAL: *Elementary*—Andrade, E. N. da C., 'The Mechanism of Nature' (rev. ed. 1936); Begeman, L., 'Everyday Physical Science' (Cedar Falls, Ia., 1923); Hart, I. B., 'An Introduction to Physical Science' (Oxford, Eng., 1925); Henderson, W. D., 'Physics in Everyday Life' (Chicago 1921); Smith, A. W., 'The Elements of Applied Physics' (New York 1923); Whetham, W. C. D., 'Matter and Change' (Cambridge, Eng., 1924); Whitman, W. G., 'Household Physics' (New York 1924); Eyring, Carl F., 'A Survey Course in Physics' (New York 1934); Heil, Herman G., and Bennett, Willard H., 'Fundamental Principles of Physics' (New York 1937); Hirst, A. W., 'Electricity and Magnetism' (New York 1937); Champion, F. C., and Davy, N., 'Properties of Matter' (New York 1937); Rasetti, Franco, 'Elements of Nuclear Physics' (New York 1936); Brown, Thomas B., 'Foundations of Modern Physics' (New York 1940); Saunders, Frederick A., 'A Survey Course of Physics for College Students' (New York 1936); Watson, F. R., 'Sound' (New York 1935); Cork, James M., 'Heat' (New York 1933); Caswell, Albert E., 'Outline of Physics,' second edition (New York 1938); Crowther, J. G., 'Men of Science' (New York 1936); Crowther, J. G., 'Famous American Men of Science' (New York 1937); Lemon, Harvey B., 'Cosmic Rays Thus Far' (New York 1936); Planck, Max, 'The Philosophy of Physics' (New York 1936); Planck, Max, 'Where Is Science Going?' (New York 1932); Crowther, J. A., 'Ions, Electrons and Ionizing Radiations' (New York 1939); edited by Compton, Ray, and Nettels, Charles H., 'Conquests of Science' (New York 1939); Darrow, Floyd L., 'Masters of Science and Invention' (New York 1923).

GENERAL: *Advanced*—Eddington, A. S., 'The Nature of the Physical World' (new ed. New York 1937); Franklin, W. S., and Grantham, G. E., 'General Physics' (Lancaster, Pa., 1930); Heyl, P. R., 'New Frontiers of Physics' (New York 1930); Houstoun, R. A., 'International Physics' (London 1930); King, F. H., 'A Text Book of the Physics of Agriculture' (Madison, Wis., 1914); Knowlton, A. A., 'Physics for College Students' (New York 1928); Lodge, Sir O. J., 'Beyond Physics; the Idealization of Mechanism' (London 1930); Luckiesh, M., 'Foundations of the Universe' (New York 1925); Millikan, R. A., and others, 'A First Course in Physics for Colleges' (rev. ed. 1937); Page, L., 'Introduction to Theoretical Physics' (New York 1928); Richtmyer, F. K., 'Introduction to Modern Physics' (New York 1928); Wilson, H. A., 'Modern Physics' (2d ed. 1937); Fermi, Enrico, 'Thermodynamics' (New York 1937); Rojansky, Vladimir, 'Introductory Quantum Mechanics' (New York 1938); Herzberg, Gerhard, 'Atomic Spectra and Atomic Structure' (New York 1937); Herzberg, Gerhard, 'Molecular Spectra and Molecular Structure, I: Diatomic Molecules' (New York 1939); Loeb, Leonard B., 'Fundamentals of Electricity and Magnetism (New York 1938); St. John, Ancel, and Isenburger, Herbert R., 'Industrial Radiography' (New York 1934); Taylor, Lloyd W., 'College Manual of Optics' (New York 1924); Klemperer, Otto, 'Electron Optics' (Cambridge 1939); Ruhemann, M., and Ruhemann, B., 'Low Temperature Physics' (New York 1938); Massey, H. S. W., 'Negative Ions' (Cambridge 1938); Darrow, Floyd L., 'Questions and Problems in Physics' (New York 1922). Also the periodicals: *Physical Review* (Lancaster, Pa.); *Journal of Mathematical and Physical Society* (Boston); *Journal of the Franklin Institute* (Philadelphia); *Proceedings of the Physical Society of London* (London); *Reviews of Modern Physics; The Journal of the Optical Society of America; Journal of the Acoustical Society of America; American Journal of Physics; Journal of Applied Physics; The Review of Scientific Instruments.*

PHYSIOCRATIC SCHOOL. See POLITICAL ECONOMY.

PHYSIOCRATS. See ECONOMICS.

PHYSIOGNOMY (Greek, *physiognomonia,* literally, the judgment by bodily appearance), the art of judging character from the countenance. We are generally impressed at first sight favorably or unfavorably, in regard to the temper and talents of others, by the expression of their countenances. As the face is that part of the body in which the noblest external organs are united, by which men put themselves in contact with the world, and, for various reasons, show most of their characteristic traits, it has been made the particular object of study by the physiognomist. In the 19th and 20th centuries the subject has been taken up in a more scientific way by physiologists and psychologists and a very extensive literature has

come into existence.

PHYSIOGRAPHY (Greek, *physics* = nature + *graphia* = description), has been variously defined. By many it is considered to be synonymous with geomorphology or geomorphogeny. In this sense it may be defined as the science which treats of land forms and their origin. On the other hand it is considered by many as equivalent to physical geography, and a recent authority has defined it as «that science which investigates the physical features of the earth and their influence on life, especially man.» The geologists in general tend to favor the former idea; the geographers the latter. It covers largely the same subject matter treated in dynamical geology. Physiography, however, investigates these facts, as a key to the study of human progress.

Change of seasons, tides, wind circulation and their geographic relations are so directly dependent on astronomic considerations that a preliminary study of the earth in its relations to the universe is essential to physiography. Because of the activity of atmospheric agents in shaping land forms, physiography is often prefaced with a brief study of meteorology and climatology, with special reference to wind, temperature and rain, their cause and distribution. A brief study of rocks and minerals is also necessary, since it is possible to understand the activities shaping the earth's crust only when we know something of the nature of the materials upon which these forces act. The subject is not infrequently divided under the headings of the atmosphere, the hydrosphere and the lithosphere.

The Atmosphere.— For a discussion of the composition and direct geologic activity of the atmosphere as a weathering agent see the section on *Work of the Atmosphere* in the article on GEOLOGY. In addition to these factors more important considerations to the geographer are winds, temperature and rainfall. The great wind belts are shown to be the result of excessive heating in the equatorial regions, causing the air drifts from the poles toward the equator, and this is modified by the earth's rotation giving belts of winds and calms. Unequal heating of land and water and the trend of mountain ranges modify the planetary wind belts and give local variations. Temperature depends primarily on latitude, but temperature belts are modified by proximity to oceans or large lakes, and by the effect of mountain ranges on wind direction. Precipitation is largely dependent on wind movements. In the equatorial belts of calms where the air is rising and cooling, rain is abundant. Deserts are the rule in the horse latitudes, where the air is descending and becoming warmer. Winds blowing over high mountains are forced to give up their moisture on the windward side, and are dry winds beyond the mountain ranges. The physiographer is concerned with all these facts in their effect on man and his activities, both directly as the sum total of climate, and indirectly in shaping land forms. See AIR; WIND; CLIMATE; GEOGRAPHY and GEOLOGY.

The Hydrosphere.— The geologic aspects of the waters of the earth's crust have been discussed in the sections on *Work of Oceans* and *Work of Lakes,* in the article on GEOLOGY. See also OCEANS and LAKES.

The ocean as an equalizer of climate is of interest to the physiographer, since it is a well-known fact that regions near the ocean do not have the extremes of temperature that exist in the interior of continents. Ocean currents are important in this respect. The warm Gulf stream and the cold Labrador current accounting respectively for the equable climate of England and the bleakness of Labrador. The ocean as a highway for human traffic and as a source of human food are within the scope of physical geography. The smoothness or irregularity of shore lines, which results from geologic processes, determine the nature of harborage. Still within the scope of the physiographer's research but less directly, so are the processes of sedimentation going on in the ocean, since these control in part the types of rocks with which man has to deal on the earth's surface.

The Lithosphere or Solid Earth.—As the home of man and the source of most of the products he utilizes, the lands hold the largest place in the research of the physiographer. Here he is faced with two problems; a study of the origin of land forms, and the determination of the influence of land forms on man and his pursuits. The first of these problems has already received attention in the section on *Dynamical Geology,* under title of GEOLOGY. The second will be briefly considered below. The major relief features of the lands are plains, plateaus and mountains, and each has its own characteristic effect on life of all kinds.

Plains.— Plains are of several varieties. Coastal plains lie between the shore line and the higher, often mountainous, interior. A typical example is the Atlantic coastal plain. Not all coasts have such plains, but when they do, the region is usually one recently emerged from the sea. It is likely, therefore, to have long straight coasts and few harbors. A slight recent sinking of parts of the Atlantic Coast of the United States has fortunately resulted in good harbors. Because coastal plains are recently emerged sea bottom, and because when submerged they were being overspread with sand deposits their soil is frequently sandy. The Atlantic Coastal Plain has large stretches of infertile soil, but because it faces America's greatest market — Europe, and has good harbors, it has undergone rapid development. Flood plains and delta plains on the larger rivers are often very extensive. The rivers are sluggish, carrying little coarse sand or gravel, and from year to year in time of flood they have spread out broad layers of fine rich soil until they comprise some of the richest agricultural lands of the world. They are usually densely populated with an intelligent and progressive class of people. Their most serious drawback is from flooding, which takes toll of many lives, and millions of dollars' worth of property each year, on the great flood plains of the world, like those of the Mississippi, Nile, Ganges, Danube and the Hoang Ho. Many other types of plains are known, and each has its characteristic relation to human activity.

Plateaus. Plateaus are elevated plains, usually bordering or enclosed by mountain ranges. For this reason they are often cut off from rain-bearing winds and are semi-arid, as our western «Great Plains,» (more properly spoken of as plateaus) and the Columbia Plateau; or truly desert, as most of the «Great Basin,» which is,

properly speaking, a plateau carrying mountain ranges on its extensive surface. Some of the very elevated plateaus, such as the Colorado Plateau, rise so high that, even in the midst of deserts, they receive enough rain to support splendid forests. Because of their great elevation and sometimes due to their aridity and isolation by mountain chains, plateaus are less favorable to population than plains. Where these high plains are deeply dissected, as in the Allegheny and Cumberland plateau region, they are often called mountains, and resemble these latter in their effect on civilization.

Mountains. These are the most striking of nature's forms and contain the grandest scenery in the world. They are also of profound influence on all life history. For the most part rocky, isolated and inhospitable, they form rather barriers than homes. It is true that mountains have many times in the history of the world offered asylums to weaker peoples, driven out of other lands by religious or political persecution, but their most important rôle is to act as barriers. They deflect winds or rob them of their rain, so that in the lee of mountains often lie deserts. They prevent the migration of many types of plants and even some members of the animal kingdom. Even to man they present serious obstacles to travel and transportation, more so formerly than now. In the isolated valleys of the more remote mountain regions are crowded the stragglers of the world's migrations, and there, old customs, traditions and manners of speech are preserved among ignorant and illiterate peoples long after they are forgotten elsewhere. Because mountains are often the seat of extensive volcanic activity, and because volcanic processes are largely responsible for deposits of valuable metals, mountains are often important mining regions. It is the search for metallic wealth more than anything else that has peopled mountain regions with progressive populations, and few important cities exist in mountainous areas outside of mining regions. See also GEOGRAPHY, PHYSICAL.

CHARLES LAURENCE DAKE,
Late Professor of Geology and Mineralogy, School of Mines and Metallurgy, University of Missouri.

PHYSIOLOGUS, an early Greek bestiary. See BESTIARIES. Consult Goldstaub, M., 'Der Physiologus und seine Weiterbildung' (in 'Philologus,' Supplementband VIII, p. 337, Leipzig 1899–1901); Hommel, F., 'Die Aethiopische Uebersetzung des Physiologus' (Leipzig 1877); Lauchert, F., 'Geschichte des Physiologus' (containing the Greek text, Strassburg 1889); Peters, E., 'Der Griechische Physiologus und seine Orientalischen Uebersetzungen' (in 15. Festschrift, Gesellschaft für Deutsche Philologie,' Berlin 1898); Thierfelder, J. G., 'Eine Handschrift des Physiologus Theobaldi' (in 'Serapeum,' Vol. XXIII, pp. 225 and 241, Leipzig 1862).

PHYSIOLOGY. The word Physiology in its original sense and according to its Greek derivation signified the science of nature but during the 17th and 18th centuries came to have the more restricted meaning of the study of *living* nature. During the 19th century, however, the name, biology, (q.v.) acquired wide usage and is now generally used to designate the study of living things. In the meantime physiology has been adopted as the name of that aspect of biology dealing with vital *activity.* In a sense, then, physiology as now conceived is the study of living things in action.

A definition of physiology frequently used is: The science of the functions of living things as distinguished from the study of their structure (morphology). The word function, implying usefulness, may be misleading. It is really employed here in the sense of functioning and refers to activity. «The dynamics of living matter,» as Jacques Loeb defined physiology, is more inclusive; but one should fully understand that dynamics may be chemical or physico-chemical as well as physical. The mechanical aspect of dynamics covers only one phase of physiology.

The scope of physiology includes the study of all living structures, animals, plants and micro-organisms. There seems to be a popular misconception of physiology as primarily the science of the functioning of the human body, the behavior of its nervous, muscular, digestive, circulatory and other organ systems. This idea of the subject arises quite naturally, partly because human physiology is of paramount interest and practical value and partly because physiological research during its earlier development was fostered chiefly by medical men and institutions. Investigations upon man and other mammals have been more completely developed than in the case of other organisms and have been the basis of brilliant advances in human and veterinary medicine, in surgery and in hygiene. But brilliant and important as such investigations have been, they actually constitute only a small part of modern physiology. Plant physiology naturally developed in connection with agriculture. The physiology of bacteria and other micro-organisms was necessarily studied as a part of research in the field of bacterial and similar parasitic diseases of plants and animals. Similarly many other aspects of physiology were investigated for practical reasons.

Physiology, however, like any other science, derives the most powerful driving force for its advancement from intellectual curiosity. This, fortunately, is not limited by practical considerations. Physiologists have indeed studied life in all its forms. The scope of physiology has been enlarged to include the study of the real nature of living matter and its processes so that the science now deals with fundamental matters such as: The composition of living substance, the molecular structure of its materials, the microscopic and submicroscopic details of its architecture, the exact description of its chemical reactions, the physical processes involved in motion, locomotion, secretion, circulation, etc., the physico-chemical explanation of regulation of the steady state of the composition of protoplasm and all other fluids of living things. In brief, the scope of physiology may be regarded as the chemistry, the physics and the physical chemistry of life in all its forms.

The methods and techniques of physiology are those of the physical sciences, Chemistry, Physics and Physical Chemistry. Thus the study of muscular motion utilizes the physics of levers, the study of nutrition depends upon chemistry and the investigation of the balance of acids and bases in the animal body is based upon the physical chemistry of ion activities.

Quantitative precision is an essential characteristic of physiological methods. Excepting insofar as they are quantitative, investigations have limited value as contributions to knowledge of the living mechanism. This is more strikingly true of physiology than of some other branches of biology because physiology deals with processes of change and not with static conditions. The detection of minute changes such as some of those which occur in living matter demands a high degree of accuracy. The development of physiology has therefore depended upon the improvement in precision of the instruments and methods of physics and chemistry. The sensitive galvanometer, the refined spectroscope, the delicate chemical balance and scores of other instruments of precision have become almost indispensable in the physiological laboratory. Electrometric methods for determining acidity, the methods of photography, both still and cinematic, and even x-ray photography, extremely sensitive methods for chemical analysis to determine biochemical substances such as sugar, uric acid, etc., and many other refined methods of physics and chemistry are employed in physiological work. Physiologists have not always followed the lead of pure physicists and chemists but have invented instruments and methods as need for them arose in the course of investigations; but on the whole, physiological advance has been conditioned by the improvement of methods in the so-called physical sciences.

Mechanism and Vitalism.—The application of physical and chemical methods to the study of physiology implies that vital activities may be thus explained. The belief that living matter is a physico-chemical machine is commonly referred to as mechanism. It is in contrast with what is usually called vitalism, the idea that vital activity involves the action of some form of energy which does not operate in accordance with the laws of physical science. It has been variously named: Vital spirits, biotic energy, entelechy, etc. The debate between the mechanists and the vitalists has been long continued and cannot be regarded as settled even now. The problem which it presents is fundamental and constitutes an important aspect of physiology. It obtrudes itself upon the mind of the physiologist repeatedly. A few instances will serve to illustrate. The passage of water and dissolved solids across membranes such as those lining the intestine is assumed to be in accordance with the laws of osmosis and osmotic pressure according to which substances become distributed by diffusion from higher to lower concentration until equilibrium is attained. But substances appear to be absorbed from the intestine against the diffusion gradient. This and similar anomalies do not prove the existence of a peculiar vital force. The action of electro-osmose due to bioelectric potentials, of absorption resulting from the colloidal structure of living tissues, of differential solubilities made possible by the complex architecture of cell surfaces, and of other physico-chemical peculiarities of the living structures might well furnish an adequate explanation and according to the mechanistic school have already been shown to operate in such a way as to justify expectation of an eventually complete solution of these problems. According to this view the living machine differs from a non-living one not by virtue of a peculiar form of energy but because it is far more complex in its structure and chemical composition than any physico-chemical system in the form of a man-made machine.

Another example of the mechanist's difficulties is found in the case of muscular contraction. Older explanations were based on ideas such as a sudden change of temperature or of localized osmotic pressures or of surface tensions within the muscle, but all attempts to explain the process mechanically proved, up until recent years, to be too crude and quite inadequate. Newer theories, however, are based upon a principle which was recently discovered by Astbury. This is the change of shape of long, thread-like molecules of protein such as are known to exist in muscle. They could shorten by a change to what might be described as a coiled condition, analogous to curling of hair. If physico-chemical conditions in an active muscle could be shown to produce these changes reversibly (such conditions are quite conceivable as shown by Ernst Fischer) an explanation of muscular contraction would be attained. It would be based, however, on molecular physics and would involve no forms of energy other than physico-chemical ones.

But the most serious problem is the origin of life. The outstanding property of life is self-perpetuation. So far as now known, living matter arises only from pre-existing life. Unless or until living matter is produced *de novo* from non-living matter this problem appears unanswerable. Yet even here, the mechanist is not without an argument. Throughout the earlier history of physiology, it was assumed that the complex carbon-containing compounds so abundant in all living matter could be produced only in or under the influence of living organisms and were therefore called organic compounds. But when (1828) Wöhler synthesized urea, a typical organic substance, by heating ammonium isocyanate which can be prepared from inorganic elements, it became apparent that artificial synthesis of organic compounds was possible. During the century following Wöhler's discovery, progress in synthetic chemistry, at first slow, showed a rapid acceleration and attained such brilliant results that one can scarcely set any limit to possibilities of its future accomplishments. Representatives of each of the classes of organic compounds, widespread and abundant in living things, have been synthesized: Sugars, other carbohydrates, fats, fat-like compounds, amino acids and protein-like substances. Even compounds so elusive as the hormones and so unstable as the vitamines have been prepared by means of artificial synthesis and progress in this field is at present very rapid. One must admit, however, that in spite of much effort no true representative of the natural proteins, which have enormous molecular weights and an extremely complex structure, has been produced artificially as yet. Moreover, complete knowledge of artificial synthesis of all the chemical compounds of living matter would still leave unsolved the problem of its structure. The architecture of living substance, even in its simplest forms, is extremely complex. Not only the microscopic structure shows complexity of its intimate arrangement of materials, but submicroscopic formations, involving the delicately

balanced orientation of molecules in minute films of one or a few molecules in thickness, apparently exist at the numerous surfaces and interfaces of the microscopic structures. Considerable progress has been made in the production of artifacts which imitate these fine structures in some respects. Indeed this aspect of physiology has already developed into a fairly well characterized branch of the subject and is called *plasmogeny*. It is, however, in a relatively primitive state and no artificial system has been set up to imitate more than one or a very few of the peculiarities of vital processes. Even these systems have been constructed in some cases from materials not found in living matter. They do, however, justify the hope of future progress.

Whatever may be the future trend of the discussion of vitalism vs. mechanism, it seems obvious that the *research* physiologist is, tacitly at least, a mechanist. He pursues his investigations in the belief that the methods of the physical sciences will yield valid physiological results. The brilliant successes already attained justify the hope that the nature of life may be elucidated. Any other belief would tend to paralyze the progress of physiology.

The History of Physiology.—The ancient Greek philosophers and physicians were naturalists of no mean ability. Aristotle, especially, collected a vast amount of information on plants and animals. Some of his writings dealt with physiological matters. But Galen, a Roman physician of Greek birth, wrote the most monumental work of ancient science. It was primarily a system of medicine but undertook to explain the working of the human body. From the time of its appearance (2d century A.D.) until the renaissance, it was regarded as embodying the whole of medical, anatomical and physiological knowledge. So great was Galen's prestige that he was regarded as the final and absolute authority whose statements could not be questioned. The relatively meagre writings of the so-called dark ages and even up to the 16th century were mere restatements of Galen's work. The first outspoken questioning of his authority, appearing in written form, was the famous work of Andreas Vesalius (1514–64) professor of surgery at Padua. He wrote on the basis of his own very extensive dissections. His book, *Fabrica Humani Corporis* (Structure of the Human Body) was primarily an anatomy although it dealt with some matters of physiological significance. Nevertheless, Sir Michael Foster in his 'History of Physiology' suggests that the science as we now know it begins with Vesalius because he first broke the power of authoritarianism which up until his time had dominated scientific as well as other thought and had paralyzed the progress of science. The year 1543, when the *Fabrica* was printed in Basel, may thus be regarded as a turning point.

Some physiologists would prefer to think of modern physiology as beginning with William Harvey (1578–1667), English physician, teacher of anatomy at the Royal College of Physicians in London. He is usually credited with the discovery of the circulation of the blood as described in his famous volume (1628) *Exercitatio de Cordis Motu*. True, as many writers have pointed out, Harvey was foreshadowed by earlier workers: Vesalius, Matheus Realdus Columbus (1516–59), who gave an essentially correct description of the pulmonary circulation; Michael Servetus (1511–53), who also described the pulmonary circulation and may have been copied by Columbus; Andreas Caesalpinus (1519–1603), who taught that the blood flowed out of the heart into arteries and through veins into the heart; Hieronymus Fabricius (1537–1619), who discovered the valves in the veins and was Harvey's teacher of anatomy at Padua, all these doubtless exerted more or less influence upon Harvey. Nevertheless, Harvey's own dissections and especially his vivisections were the basis of his writings. He was the first to describe the circulation as a whole and to make all of the crucial observations for himself. It was still necessary for Harvey to theorize in part. He was obliged to postulate the passage of blood from arteries to veins through some sort of minute channels in the tissues. The fine capillaries affording this connection were unknown at that time. The microscope had not yet come into use. The capillaries as an actual part of the circulatory system were seen under the microscope and described by Marcello Malpighi (1628–94), professor of medicine at Bologna. He described (1661) the capillary circulation of the frog lung. A Dutchman, Antony van Leeuwenhoek (1632–1723), whose hobby was the grinding of lenses and the fashioning of microscopes, described (1688) the capillaries of the main or systematic circulation. He was also the first to give a really satisfactory description of the blood corpuscles.

Giovanni Borelli (1608–79), professor of mathematics at Messina and for a time at Pisa, wrote a description of animal motion, *De Motu Animalium* (1681), which showed the influence of physics then developing through the work of Galileo and others. Borelli's treatment of the subject was distinctly mathematical and described the action of muscles in a completely mechanistic way. He explained the contraction of muscle as a shortening and thickening of its motor fibres. He was the first to teach this conception, essentially correct as far as it went. Previous ideas on the subject had been mystical and postulated a sudden expansion of the muscle by «animal spirits» produced under the influence of the nerves. Borelli's ideas regarding contraction were influenced no doubt by the work of the Danish anatomist, Nicolaus Stensen (1638–86), who had described the fibrous structure of muscle in connection with his numerous anatomical discoveries based largely on his use of the microscope.

In the meantime glands and their functions were under observation. The actual production of a secretion was first described by the English physician, Thomas Wharton (1614–73), who in his treatise on glands (1656) described the duct of the submaxillary gland and showed that it really delivered true saliva to the mouth. The corresponding duct of the parotid gland was discovered by Stensen in 1661. He also explained the relation of the tear glands and their ducts to secretion. Francis Glisson (1597–1677), an English physician, published (1654) his work on the liver, *De Hepate*. Lorenzo Bellini (1643–1703), a pupil of Borelli and later a professor of anatomy at Pisa, gave (1662) a description of the kidneys, *De Structura Renum*, which showed the action of the kidney tubules although his ideas of urine secretion were too mechanical due, no doubt, to the influence of

Borelli. The great Malpighi also made important contributions to knowledge of the kidney and also of the liver and spleen. His work on the kidney (1666) was especially important. Regner de Graaf (1641–73), a Dutch physician who studied under Franciscus Sylvius (1614–72) at Leyden, devised (1664) the method of making a fistula by inserting a tube (he used a goose quill) into the pancreatic duct of a dog and thus collected pure pancreatic juice. Similarly, he collected saliva and bile. At his time, however, ideas on the nature of digestion in animals and the action of digestive juices were in a confused state. Further advances in this aspect of physiology did not come until the 18th and 19th centuries.

The 18th century saw great progress in the physiology of respiration which could be given no clear explanation until physics and chemistry had made advances. John Mayow (1643–79), while a student at Oxford, had showed that only a part of the air was necessary for life, namely, the part which was then called nitro-aerial spirit. He also explained the action of intercostal muscles in enlarging the thorax during inspiration. Richard Lower (1631–90), another Oxford physiologist, had performed the first transfusion of blood from one animal to another and had shown (1669) that the dark venous blood in passing through the lungs becomes bright red apparently, as he suggested, because it absorbs something from the air. But the physiology of respiration was not clarified until more than a century later. Joseph Priestly (1733–1804) showed that the constituent of air which was required by animals was also necessary for the burning of a candle and was given off by green plants in the «vegetating state.» But it was the great French scientist, Antoine-Laurent Lavoisier (1743–94), who really obtained exact information on the chemistry of air, gave the name, oxygen, to its vitally essential constituent and showed that it acted during oxidation in both animate and inanimate systems. He showed that carbon dioxide was a product of oxidation. This gas had been recognized by Jean Baptiste van Helmont (1577–1644), the Belgian physician who was one of the first to make quantitative chemical measurements. He called the substance gas sylvestre (wood gas) recognizing that it was formed in the burning of charcoal. Joseph Black (1728–99), professor of chemistry at Glasgow and Edinburgh, rediscovered van Helmont's gas more than a century later (1754), confirmed and extended his observations and called the gas «fixed air.» But it remained for Lavoisier to explain, in a series of papers (1775–83), the real nature of respiration, to show that oxygen was taken by the blood from the air in the lungs, that carbon dioxide was given off, and that the processes of oxidation in the animal body were comparable to those in the flame.

The 18th century also saw advances in other aspects of physiology. Hermann Boerhaave (1668–1738), professor of medicine at Leyden and an able botanist and chemist as well as physician, introduced a truly critical and judicious attitude into his writings on physiology. He refused to follow either the iatro-physical school, which regarded all physiology of circulation, digestion, muscular and nervious action as mechanically explicable, or the iatro-chemical school, which stressed chemical explanations. He seemed to sense the true values of all the learning of his time. His pupil, Albrecht von Haller (1708–77), a Swiss, who during 17 years taught at the University of Göttingen, produced one of the most monumental works of physiology of all time. This was his *Elementa Physiologiæ* (1757) of which Foster says, «Save for the strangeness of much of the nomenclature and for no small deficiencies in all that relates to the chemical changes of the body, we seem to be reading a modern textbook.» The chemical aspects of physiology were still undeveloped but even in these matters as well as in other fields of physiology, Haller showed, as did Boerhaave, a broad grasp of the knowledge of his time and a careful critique in evaluation of it. Haller's own experimentation covered many aspects of physiology. A pioneer investigator of this period, Stephen Hales (1677–1761), an English clergyman, reported in his 'Statical Essays' (1733) the measurement of blood pressure in the arteries of the horse and other data on the mechanics of blood flow. Another notable event of the 18th century was the discovery of electrical excitation (1791) an animal electricity (1794) by Aloysio (also known as Luigi) Galvani (1737–98) of Bologna, whose name is preserved in such words as galvanize and galvanometer. He showed that frog muscle twitched when it or its nerve was exposed to the action of two dissimilar metals or other source of electricity and also demonstrated that a nerve could be stimulated by a suitable contact with other animal tissues. René de Reaumur (1683–1757), a French investigator working independently in Paris, published (1752) a work on digestion in which he reports at some length his observations on a kite. This bird normally ejects from its stomach indigestible substances which are swallowed with food and Reaumur was thus able to observe what happened in the bird's stomach to food enclosed in perforated metal tubes. He obtained proof of the solvent power of the gastric juice for meat and some other foods. He also observed that digestion could occur without putrefaction. Some years later this method was used and improved upon by the Italian, Lazaro Spallanzani (1729–99), usually referred to as the Abbé Spallanzani. But even at the close of the 18th century the chemistry of the gastric and other digestive juices remained to be investigated.

In the 19th century, however, a peculiar accident opened up new possibilities of discovery. The famous case of Alexis St. Martin, wounded by a close discharge of a shot gun, was attended by the American army surgeon, William Beaumont (1785–1853) who found that after the wound healed a permanent opening (fistula) was formed through the body wall and into the cavity of the stomach. Beaumont made extensive observations on the digestion of food, sampling the stomach contents through the fistula. He also collected gastric juice which for a chemical analysis had to be sent as far as Sweden to Berzelius. Beaumont's 'The Physiology of Digestion' (1828), reporting his observations, suggested the operative technique for producing artificial fistulas in living animals. Such experiments in many laboratories have resulted in knowledge of the chemical

composition and physiological action of all the digestive juices.

Up to about the fourth decade of the 19th century, discoveries of lasting significance in physiology, as in physics and chemistry, were separated by relatively long intervals; but during the last 100 years advances in physiological knowledge have occurred ever faster and faster. This, of course, is a part of the concurrent development of all science. To list the significant names and discoveries of physiologists of the past century is impossible in a short article. Only a few pioneers can be mentioned.

Those who developed the chemical aspects of physiology include: Justus von Liebig (1803–73) who might perhaps be called the father of physiological chemistry; a number of other German chemists, Baumann, Bunge, Hammarsten, Hoppe-Seyler, Kossel, Kühue, Pfluger and Emil Fischer, who somewhat later achieved monumental results in researches on the chemistry of the purine substances, the sugars and the proteins; Claude Bernard (1813–78), who discovered glycogen and worked out much of the physiology of carbohydrate metabolism; Louis Pasteur (1822–95) who, though chiefly known as the founder of modern bacteriology and immunology, was an important contributor to biochemistry through his work on fermentation and stereochemistry.

Among the outstanding investigators in nerve physiology were Sir Charles Bell (1774–1842) whose work on the brain and nerves (1811) opened a new chapter in studies of the nervous system; Francois Magendie (1783–1855) who, by a study of the roots of spinal nerves, gave the first clear distinctions between afferent (sensory) and efferent (motor) nerves and thus advanced the physiology of reflexes; Marie-Jean-Pierre Flourens (1794–1867) who gave (1824) a remarkable exposition of the physiology of the cerebellum; Johannes Müller (1801–58) who showed (1826) that the effects of excitation of any specific nerve were determined by the place of ending of the nerve and not by the nature of the exciting stimulus, an idea which came to be known as the Müllerian doctrine of specific nerve energies and greatly helped to clarify nerve physiology; Claude Bernard, who left his imprint on many branches of physiology, showed the action of the vaso-motor nerves controlling constriction and dilatation of arteries; Ernst H. Weber (1795–1878) and Eduard F. Weber (1806–71) who demonstrated (1845) that stimulation of the vagus nerve caused slowing or stoppage of the heart and thus opened up what has since become of considerable importance in physiology, inhibitions involving the nervous system; Henry P. Bowditch (1840–1911) who, in working out the peculiar properties of heart muscle, demonstrated (1871) what he called the «all or none» law of the heart which states that the cardiac muscle, if it contracts at all, does so to the fullest extent possible under the prevailing conditions, a law which has subsequently been shown to apply to the transmission of the nerve impulse at maximum intensity or not at all and also, with due limitations, to the activity of any muscle fibre.

At the close of the 19th century, digestion, circulation, respiration, muscle-nerve physiology and other aspects of the subject were well developed but knowledge of the ductless glands was still very meager. Although these structures are numerous in the mammal and are present in many other animals, their physiological action seemed to baffle investigation. A few physiologists, including Claude Bernard, had sensed their importance and had to some extent anticipated the discoveries that were to follow. One of the earlier discoveries, giving definite evidence, was that of G. Oliver and Sir Edward Sharpey-Shafer, who showed (1894) that the adrenal gland yielded an extract very potent in raising blood pressure and causing other marked effects when injected into the living animal. Another definite advance was the demonstration (1902) by William M. Bayliss and Ernest H. Starling that a suitable extract of the duodenum injected into an animal with a pancreatic fistula would cause secretion of pancreatic juice. They proposed to call this substance secretin and also introduced the term, hormone, to apply to this and similar substances acting as chemical messengers. In the meantime considerable information was accumulating in connection with several of the other ductless glands, especially the thyroid, parathyroids and pituitary. Information was based at first on pathological observations and comparatively crude experiments. From these beginnings, however, there has been, during the past forty years, a marvelous development of the science of *Endocrinology,* which includes the physiology of all the ductless glands.

Developments subsequent to 1900 may be regarded as present day physiology and will not be treated in this brief historical account.

Chief Divisions of Physiology.—Physiology may be divided into fields of interest which might be differently defined by different writers. The following would seem to be a fair designation of the chief subdivisions:

1. *Physical physiology,* also called *biophysics,* which includes study of the electrical phenomena of living things (bioelectric potentials, action currents, etc.); the propagation of the nerve impulse and all other states of physiological excitation; the physics of muscular contraction and other protoplasmic movement; the mechanics of the circulation of blood and other biological fluids; the physical aspects of the gaseous exchange between an organism and its environment (respiration); the physics of growth; the effects of radiant energy (heat, light, x-rays, radium, etc.) on living things; and the physical forces determining the structure of protoplasm;

2. *Chemical physiology* or *biochemistry* which includes the chemical composition of living matter and substances produced by it or as a result of its death; the chemistry of foods; the nutritive requirements of organisms; metabolism (the chemical changes occurring in living matter); the chemistry of growth, including the synthesis of compounds produced in living structures; the chemistry of digestion and of similar processes such as fermentation; and the chemistry of biological fluids (blood, lymph, bile, sap, etc.);

3. *General physiology* which is difficult to define sharply, since it overlaps other fields and covers the study of those biophysical and biochemical phenomena more or less common to all living things; it includes study of the conditions necessary for life; fundamental pro-

toplasmic properties; the nature and the rôle of all the substances occurring generally in protoplasm; the physico-chemical structure of living matter; the nature of the process of response to stimuli and the nature of environmental conditions which constitute stimuli, in fact, the whole matter of excitation and inhibition, the sensitive responses of living matter to change; the processes of diffusion, osmosis and absorption which determine the passage of material into and out of and through cells and also determine osmotic pressures; those aspects of metabolism which are common to all life as is the case in the synthesis of proteins, carbohydrates and some other substances, and in biological oxidation; the fundamental characteristics of protoplasmic motility such as streaming movements (cyclosis) contraction and relaxation of muscle and other fibres, changes of shape, etc.; vital self-regulatory processes by which living things tend, except in so far as growth and senescence supervene, to maintain themselves in a state of relatively constant composition and activity; and all aspects of cytophysiology which, inasmuch as living matter is generally organized into cells, constitutes a large aspect of general physiology;

4. *Applied physiology* which includes the physiological aspects of many studies, Hygiene, Dietetics, Pharmacodynamics (that part of Pharmacy (q.v.) treating of the action of drugs), Agricultural Chemistry; and many aspects of medicine and surgery;

5. *Comparative physiology* which comprises the study of the differences and the similarities of the physiological processes of the different species; it has been developed rather fully in the case of animal species but is also growing rapidly in connection with other organisms;

6. *Special physiological sciences,* which, because of the technical intricacies or of the extensiveness of the data involved in their study, have become highly developed branches of biology and include: Neuro-physiology, physiological behavior of nerves and nervous systems; Endocrinology, largely the physiology (though partly the morphology) of the glands of internal secretion; the physiology of reproduction which, especially in its comparative aspects, is highly complex; and Organology and Developmental Mechanics, comprising studies of those forces (chemical, as in the case of organizers or evocators, physical, as in the case of pressures and bioelectric potentials) that predetermine the formation of specialized tissues and organs during the development of an individual from the ovum.

Interrelations of Physiology with Other Branches of Biology.—In addition to the relationships indicated under applied physiology and special physiological sciences, physiology joins hands with numerous other biological sciences:

1. *Taxonomy,* the classification of living things, although based chiefly on Morphology, is to some extent also dependent upon Physiology. For example, a classification of an organism with plants or with animals may be determined in some cases according to whether or not it can carry on the physiological process of photosynthesis;

2. *Ecology,* the study of the interrelations of organisms with their environment including their adaptations, is very largely a matter of physiology;

3. *Psychology* to a considerable extent overlaps the field of neuro-physiology. Indeed, a very large part of the research work now being pursued by psychologists is strictly physiology of the nervous system;

4. *Evolution,* in tracing the origin of species, deals to some extent with the evolving of their physiological mechanisms in addition to its main theme, the evolution of organic form;

5. *Genetics,* the science of heredity, involves a considerable amount of physiology such as the chemical nature of the substances which serve as the bearers of heredity, the relative importance of the materials (chromosomes, cytoplasm, etc.) of the egg and sperm in determining heredity and the physiological mechanisms by which inherited characters come to express themselves in form and behavior during growth and maturity;

6. *Specialized biological sciences,* such as Forestry, Plant and Animal Breeding, Animal Husbandry, and similar arts pursued largely by the scientific method, depend upon physiology to a considerable degree. Oceanography, though a very complex science embracing many types of study, includes problems of all life in the sea, comparative physiology, ecology, etc. Mammalogy, Ornithology, Entomology, Parasitology, etc., are all biological specialties which are obviously physiological to a greater or less extent.

The main subdivisions of biology: zoology, botany, bacteriology and protozoology, all overlap physiology as was implied in stating the scope of physiology. What has been said regarding these relations should not be taken to mean that physiology is more distinctly fundamental than are some of the other branches of biology. Just as they are largely dependent upon physiology, so it too is powerless to advance without the aid of related sciences. This is especially true of the morphological ones (anatomy, histology and embryology) inasmuch as function is clearly understood only when structure is known.

Modern Trends in Physiology.—A rapid advance on many fronts of the field of physiology is occurring. Physiological research pervades the entire field of biology. One gains the impression, upon surveying current biological journals, that a considerable number of biologists, who by training and profession are nominally anatomists, ecologists, geneticists or other supposedly non-physiological biologists, are publishing reports of research in pure physiology. This trend is only the natural result of modern developments in *experimental* facilities and techniques. The more *descriptive* aspects, dependent upon observation rather than experiment, matured early in biology as in other sciences; but physiology is still in that fascinatingly immature state affording rich discoveries to the investigator. The trek of non-physiological biologists into experimental work is sometimes concealed by new terminology. Thus the anatomist's study of the physiology of embryological development is named Developmental Mechanics while the psychologist's study of the physiology of the nervous system goes under various names, Neurology, Conditioning, etc. In addition to recruits from these sources, the number of investigators who are professed physiologists increased very rap-

idly during the period from 1910 to 1935 and is probably still increasing. The high pressure for publication of researches in the still increasing and vary large number of physiological journals is alone evidence that a veritable army of physiologists is at work. It is only fair to add that physiology receives much advancement, now as throughout its history, from investigators who are primarily physicists or chemists.

From the almost bewildering array of new discoveries, a few groups which represent astounding and significant advances may be mentioned.

1. The development of the study of *intermediary metabolism,* the chemical changes occurring in living matter itself, is remarkable. It was comparatively easy to discover the chemical composition of the foods utilized by plants and animals and of the waste products. This yielded data on the balance of metabolism. But it has been difficult indeed to discover the intermediate chemical changes because ordinary methods of analysis tend to modify or destroy protoplasm so that it no longer metabolizes normally. The development of indirect methods such as the study of minute changes in concentration of constituents of blood and other body fluids and the use of cellular enzymes (q.v.) in a more or less isolated condition have provided successful means of attack. The metabolism of the individual amino acids, of sugars, of fats and of many other important substances is rapidly unfolding.

2. The study of *biological oxidization,* a special phase of metabolism, is rapidly solving a very difficult puzzle. Among the parts of the puzzle which are being put into place are the enzymatic oxidative systems, the cytochrome system and the flavo-protein system, which are being studied in many laboratories. Another outstanding feature is disclosure of the large extent to which substances such as carbohydrates and fats are changed into phosphate-containing complexes (phosphorilization) in order to undergo oxidation.

3. *Electrical phenomena* constitute a field of lively investigation. The origin and significance of bioelectric potentials are important phases. Studies of the electrical changes during activity, at first developed in connection with nerves and voluntary muscles, later studied elaborately in connection with the heart (see ELECTRO-CARDIOGRAPH) are now being extended to all manner of living structures. Exceedingly minute details may be disclosed and accurately timed by use of the sensitive string galvanometer (q.v.) and the still more sensitive oscillograph.

4. The nature of the process of *excitation* is under intensive investigation which promises to disclose how the intimate submicroscopic structure of protoplasm confers upon it highly sensitive responsiveness. Among the recent disclosures are the effects of concentrations of potassium and calcium ions and the action of chemical transmitters such as acetyl choline.

5. Investigations of the *permeability of cells* to water and dissolved substances are yielding results of truly fundamental importance, leading to new theories of the structure and the energy of the surfaces of protoplasm.

6. The mechanics and the chemistry of *muscular contraction* are under very active investigation. The illuminating discoveries of the past ten years might be regarded as more significant than all the prior work in this field.

7. Recent advances in *nutrition* are pretty generally recognized as spectacular. Outstanding is the discovery of the effects of minute quantities of previously unrecognized animal food requirements, the vitamins (q.v.) and the «trace elements» such as copper, cobalt, iodine, manganese and others. The protein requirements of animals have been investigated both qualitatively and quantitatively. Equally important discoveries in plant nutrition are appearing.

8. *Endocrinology,* one of the newest of the branches of Biology, shows the most spectacular advances in its physiological aspects. The very large number of the investigators in this field is in part the result of the numerous practical applications in therapy and in the study of the pathology of the endocrine glands. Not only the physiological action of all these numerous glands is being investigated by the biochemistry of the hormones which they produce is being successfully studied. A number of them, adrenaline, thyroxine, and several of the sex hormones have been actually synthesized artificially. The chemistry of all of them is rapidly advancing.

9. *The physiology of the organism as a whole* constitutes another discernible modern trend. Physiology formerly stressed the study of organs and systems of organs, later under the influence of Verworn, emphasis on cell physiology developed. He wrote (1894) «Every cell, wherever it is, performs all the elementary functions of life.» He suggested that cytophysiology afforded the key to the mystery of life. The inadequacy of this view has been exposed in several connections.

10. Rapid advances in *applied physiology* are numerous and important. The use of hormones and other applications of endocrine physiology were mentioned. Hygiene and public health are still making use of physiological developments. Closer co-operation between physiologists and practical biologists affords hope that other uses of physiology will continue in the service of man.

PHYSIOLOGY OF TASTE, or **PHYSIOLOGIE DU GOÛT.** This work may be compared in a distant way to the 'Compleat Angler' of Izaak Walton. It is a similar repertory of information, percept, anecdote and

personal reflection, a similar stream of pleasant talk by a charming companion who discourses most entertainingly of what has been, after his business, the most unfailing interest of his life. Its author, Brillat-Savarin (q.v.) (1755–1826), was an honored magistrate and jurist, but his fame rests wholly on this volume of "meditations of transcendent gastronomy," as he calls it with mock grandiloquence and with a humorous reference, perhaps, to Lamartine's 'Poetical Meditations,' which had been the great literary success a few years before. He worked at it affectionately for many years, and only gave it to print, and then anonymously, a year before his death. Its contents are most various. First come 30 "meditations" on such matters as the senses, taste, smell, appetite, thirst, the pleasures of the table, digestion, rest, sleep, dreams, diet, corpulence, fasting, the history of cooking, in which physiological fact and theory alternate with stories of remembered feasts, bits of strange lore from far afield with descriptions of culinary *chefs-d'œuvre* that makes your mouth water, racy anecdotes with practical recipes. Then, as if the meditations had not afforded him latitude enough, he adds 27 *variétés*, "miscellanies." But various as are the contents, they all turn about the business or pleasure of eating. Gastronomy is declared to be the chief of all sciences. "The destiny of nations depends on how they are fed," and "Tell me what you eat and I will tell you who you are," are among the aphorisms which serve as its basis. And the intentional mock grandiloquence of the style and the apparent levity of the author should not deceive us as to the seriousness of the work. There is much in the book, in its intention, at least, to justify the title, "physiology of taste." It was one of the first attempts to approach the spectacle of human conduct from the physiological side. It is perhaps not without significance that Balzac admired it much and afterward wrote a 'Physiology of Marriage' and a 'Physiology of Dress.' However, Balzac recognized that the charm of the book lies, not in the matter, but in the style and in the genial, lively and humorous personality that shines through it.

PIACENZA, Pietro, Italian clergyman: b. Piacenza, Italy, 21 Jan. 1847. He was educated at Alberoni's College, Piacenza, and ordained to the priesthood in 1869. From 1870 to 1878 he was professor of history and liturgy, at Piacenza Seminary; from 1878 to 1897 he was archpriest and pastor of Fiorenzuola, and after 1897 archpriest of the cathedral of Piacenza. Since 1904 he has been visitor apostolic of Rome and its district, and after 1907 professor of liturgy in the Roman Seminary. Dr. Piacenza has published 'Storia del B. Gregorio X' (1876); 'Quæstiones Liturgicæ' (1887); 'Il Rito della consacrazione di un vescovo' (1899); 'Un curioso documento della giovinezza di Pietro Giordani' (1901), etc., and contributions to *Ephemerides Liturgicæ, Archivo storico,* etc.

PIACENZA, pē-ä-chĕn'zä (ancient PLACENTIA), Italy, city, capital of the province of Piacenza; one-third mile south of the Po River; 43 miles southeast of Milan and 35 miles northwest of Parma. It is a fortified city and has always been considered of great strategic and commercial importance. The fortifications are kept in repair and improved from time to time as new defense methods are introduced. The city was founded 219 B.C. by the Romans. About 20 years later it was destroyed by the Gauls. When the Via Æmilia, a Roman military road, was constructed, the western terminus was at Piacenza. The city entered the Lombard League in the 12th century, later fell under the domination of the Visconti, the Sforza, and the popes. In 1545 Pope Paul III presented it together with Parma (q.v.) to his son Pier Luigi Farnese. From then on its political fortunes followed those of Parma.

Among the historic buildings of Piacenza is the ancient church, San Sisto, rebuilt in 1499–1511, for which Raphael, about 1515, painted the Sistine Madonna. This picture was sold, in 1753, to Frederick Augustus of Saxony and is now in the Dresden Gallery. Other noted buildings are the cathedral (1122), in which there are paintings by Guercino, Carracci and others. The church of Santa Maria di Campagna has fine frescoes by Pordenone; the square has some fine equestrian statues. The public library has about 120,000 volumes. The Palazzo Municipale is an impressive building dating back to 1281. The huge, uncompleted Palazzo Farnese, begun in 1558, now serves as a military barrack. It has modern theatres, hospitals and educational institutions. It has considerable manufacturing interests, especially in silk, cotton and woolen goods, pottery, wine, cheese and machinery. In the vicinity are valuable marble quarries. Pop. commune about 61,676. Consult 'Monumenta Historica ad Provincias Parmensem et Placentinam Pertinentia' (8 vols., Parma 1855–60); Giarelli, 'Storia di Piacenza' (2 vols., Piacenza 1889); Jordan, L., 'Die Renaissance in Piacenza' (in 'Archiv für Kultur-Geschichte,' Vol. V, Berlin 1907); Siro Corti, 'Provincia di Piacenza' (Turin 1893).

PIACERE is D'Annunzio's first novel, and was first published in 1889, when he was 26 years old. A more fitting title than the one which the author gave it is that of the English translation by Georgina Harding, 'The Child of Pleasure' (Boston 1910), which in turn was suggested by the still more illuminating and apt title of the French translation, 'L'Enfant de la Volupté.' The story is that of a workless yet wealthy young man of the Italian nobility who has a love for, and succeeds in winning, several women, and who has more momentary affairs with a great many others, all of them, however, of his own class. The two most interesting parts of it are the description of a horse race for "gentlemen" riders, in which the hero races against a friend the love of whose mistress, the wife of a mutual

friend, he has appropriated, and the description of the duel on the following day between the winner (of the race as well as of the lady) and the loser, which event interrupts the love-making of the former because of a serious wound received. Both incidents are familiar to novel readers. There is no plot. The book is a painstaking exposition of an artificial state of mind and of sensual emotions which it engenders. The attitude toward women therein displayed is not wholesome: they merely present possibilities for material pleasure. The very completeness of its psychological detail renders it at least monotonous, and the normal, healthly mind conceives no sympathy, to put it mildly, with D'Annunzio's hypocritical and obnoxiously aristocratic hero. In workmanship the story does not present a high degree of skill and a number of the links are plainly conventional. However, it must be remembered that it is a work of youth. Consult Sedgwick, H. D., 'Essays on Great Writers' (Boston 1903).

AMERICO U. N. CAMERA.

PIAGGIA, Carlo, Italian explorer: b. Lucca, Italy, about 1822; d. Sennaar, Sudan, 17 Jan. 1882. He went to Egypt when young, was with Antinori in Bahr-el-Ghazal 1860; went with Gessi to the lakes of the Nile in 1876 and was the first European among the Nyam-Nyam. His ethnographic collection was acquired by the Berlin Museum. He published 'Dell' arrivo fra i Niam-Niam' (Lucca 1877).

PIANISSIMO, the superlative of piano (Italian for soft and low); piano is used in music in contradistinction to forte. The symbols for these terms are pp. and p. Some composers, especially Verdi, Berlioz and Tschaikovsky use the symbol pppp. and even ppppp. to express that they desire the softest pianissimo possible, while many others frequently indicate this by ppp. See MUSIC.

PIANKISHAW (pī-ăn'kē-shâ) **INDIANS,** a small American tribe of the Algonquian family, originally a part of the Miamis (q.v.). The tribe never numbered over 1,500. They removed to the Indian Territory, now Oklahoma, from Kansas in 1867, after selling all their lands in the latter State. In 1900 only 234 remained; and in 1906, when they were included with the Peorias, there were only 192 of the merged tribes, none of whom was of pure blood. See Hodge, F. W., 'Handbook of American Indians' (Washington 1910).

PIANOFORTE, a stringed musical instrument commonly known as a "piano," and essentially consists of a series of stretched, graded and tuned wires which are struck by felt-covered hammers by the operation of keys conveniently arranged in a keyboard. The term, "pianoforte," which is the original term designating the instrument, is derived from the Italian "piano," soft + "forte," loud; while the term "piano," usually designated by p., is a sign used in music to denote softness, that is, the strain where the indication occurs is to be played with less than the average intensity. Similarly, pp., or ppp., abbreviations for "pianissimo," signify very soft.

The pianoforte is probably the most extensively used of all musical instruments. It was evolved directly from the clavichord and harpsichord, which were undoubtedly elaborations of the monochord or pitch-carrier with one string, although even the approximate date or the name of the inventor who first put keys to a monochord and called it a clavicordium is quite unknown. Virdung, in his 'Musica Getutscht,' published in 1511, states his inability to ascertain those facts, although it is well known that Pythagoras, in the 6th century B.C., measured a vibrating string stretched between raised bridges on a resonance box, and by shifting those bridges he accurately determined the intervals of the Greek diatonic scale. It is supposed that Pythagoras obtained the monochord embodying the principle of the stopped string upon a finger-board from Egypt, where it had been known for ages before his time. After Pythagoras, the monochord became, in Greece and Europe, the canon or rule for the measurement of musical sound intervals, and continued to be so employed up to the 11th century, A.D., when it was transformed into a polychord of four strings, to facilitate the melodic division of the Gregorian tones — the Plain-Song of the Church as used in the Ritual, and were known under a great variety of names such as clavichord, clavicordium, spinet, virginal and regal.

The early clavichords had a compass of four octaves. The natural keys were made of citron wood and the sharps of ebony. The damper was a narrow band of felt attached with glue to the hitch-pin block, opposite to the wrest-pin block, and the bridge was curved. As they were strung with wires in equal lengths, they were for a long time regarded as sets of monochords, the scaling being effected by the line of the tangents attached to the keys on the left-hand side of the player, while the three or more sounding-board bridges rested upon the narrow belly on the right. Owing to the length of the scale the longer instruments were not capable of being tuned higher, giving them a weak but delicate tone which responded to the gradations of the player's touch. The tangents were upright blades of brass fastened into the keys and beaten out at the top so as to touch equally the one string or the two or three unison strings forming a note. The tangents thus constituted a series of bridges or sound exciters, and each of the little groups of strings thus formed was acted upon by two or sometimes three or four tangents to obtain as many notes. The damping was contrived with a cloth interwoven among the strings behind the line of tangents. This cloth instantly dampened the vibration of the strings when the finger released the key and the tangent quit the string.

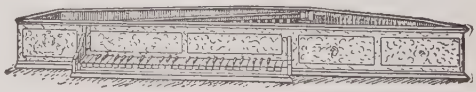

FIG. 1.—Queen Elizabeth's Virginal, South Kensington Museum, London.

Clavichords with pedals are mentioned by Virdung and Reynvaan, and are also particularly described by Adlung, indicating that some of the instruments had two octaves and a note of pedals attached to a separate clavichord pedalier and "fretted," there being three strings in the lower and four in the upper range for each pedal note. The terms virginal or spinet

generally indicate one and the same instrument without regard to form of construction, but practically limited to a plectrum (jack) clavier with one string only to each note (see Fig. 1). Its earliest recorded name is the clavicymbolum, occurring in the rules of the Minnesingers under the date of 1404. It is the Latin for psaltery, an instrument of the dulcimer kind, to which a keyboard was added and suggests an ecclesiastical or monastic origin. Virginal was the English name of the spinet, and was so called probably on account of its appropriateness for girls as compared with the contemporary lute which was a more difficult and manly instrument, rather than the assumption that Queen Elizabeth was a skilful performer on it, especially as the name was current in the reign of her grandfather, Henry VII. According to Scaliger, who wrote in the latter part of the 15th century, the name spinet is derived from the little quill point or plectrum, as an improvement upon the instruments previously known as monochordum and harpsichordium, a keyboard psaltery of harp shape. On the other hand, the Italian expert, Signor Ponsicchi, attributes it to a Venetian maker, who signed and dated an instrument of this kind «Ioannes Spinetus, Venetus Fecit; A.D. 1503.» The virginal that is assosociated with Queen Elizabeth is now in the South Kensington Museum, London, and may be described as an Italian pentagonal spinet

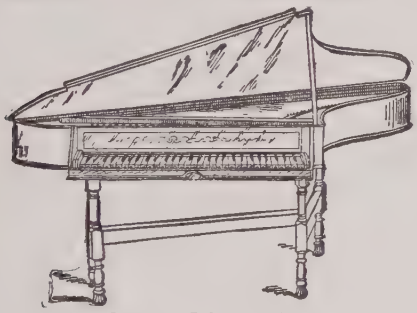

FIG. 2.—Spinet — 1710.

(see Fig. 2). Italian spinets were made of cypress wood, and as the utmost vibration was sought for by the makers, both case and belly were constructed of that material. They consisted of two cases — the inner rough, but possessing a free and satisfying quality of tone, while the outer received great care in workmanship and was often beautifully decorated. The pentagonal or heptagonal spinets had false cases like the clavicumboli or harpsichords, from which they could be removed when required for performance, while the oblong Italian makes were inseparable from the outer case like the modern pianos. Until the 17th century, the keyboard was usually an external addition to the case, when Rosso, a Milanese maker, set it back into the body of the instrument, a recessing which was generally copied afterward (see Fig. 3).

The harpsichord is a double, treble or quadruple spinet, the sounds being excited by a jack and quill plectrum, as in the case of the virginal or spinet. More exactly stated, instead of having one string to a note, as in the virginal or spinet, it has two, three and sometimes four strings to a note, which, with the exception of the common features of the case, sound-board, wires and keyboard, it differs entirely in sound, excitement and effect from the clavichord. It has an individuality of tone not possessed by the pianoforte, and a brilliancy of effect be-

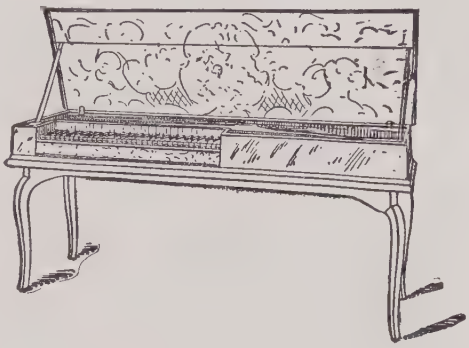

FIG. 3.—Clavichord, Taphouse Collection, Oxford.

yond the capacity of the clavichord, but in expressiveness depending upon touch its power is much less than either.

The harpsichord was a much favored musical instrument during the 17th century, occupying the place now filled by the grand piano, and while not so much a solo instrument, it was of considerable importance in the orchestra, its player generally assuming the responsibility of conductor. The complex character of its mechanism required a larger and differently shaped case to that of the spinet and prefigured that of the grand piano, the wing-shape giving rise to the German name fluegel, also kielfluegel, from the plectrum (kiel, quill) producing the sound. With the Italians—it was known as the clavicembolo, while the French called it clavecin. In the English term harpsichord, the harp disposition is recognized in contrast to the trapeze shape of the spinet, which appeared about the same time — the earlier part of the 15th century.

The description of a very fine example of a Roman harpsichord in the South Kensington Museum, London, inscribed and dated «Heironymus Bononiensis Facietat Romae, MDXXIX,» will serve to illustrate the general character of the instruments of that time. It has one keyboard and two unison strings to each note; boxwood natural keys, with an apparent compass of nearly four octaves, E to d^3, which by a short octave in the bass becomes C to d^3. In the Italian instruments no change of power was attainable by stops, while the pedals, as in the

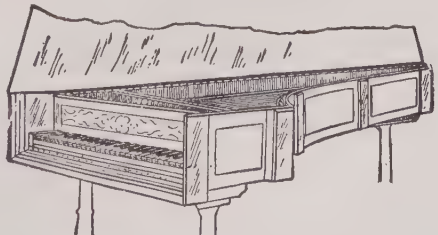

FIG. 4.—Trasuntino Harpsichord — 1531.

Trasuntino harpsichords, controlling a sordino for muting, were a very late addition (see Fig. 4). The highest credit for excellence in the manufacture of harpsichords belongs to the

famous Ruckers family of Antwerp. The earliest instruments made by them bear the date of 1590, and the latest 1659, a short period of splendid work. Of their instruments there are 70 existing specimens, including some of great beauty of decoration, but they have all been subjected to one or more alterations of scale and keyboard compass. It is claimed that Hans Ruckers, the elder, added the octave register and steel wire instead of brass for the treble notes, designed a second keyboard in imitation of the organ and increased the number of keys from E to C^3 to C-c, thus making the short octave in the bass a long or chromatic one down to the lowest notes. The most famous harpsichord makers of the 18th century were Burkat Shudi (Burkhardt Techudi) and Jacob Kirckman (Kirchmann) in London, and Taskin in Paris. Burkat Shudi began business in 1732 in the house still occupied by his descendants, the Broadwoods, 33, Great Pulteney street, Golden square, London; while Kirchmann continues to be represented by his descendants in a first-class London pianoforte manufactory.

About this time, makers, more or less controlled by the prevailing style of domestic furniture, substituted the more rigid cases of walnut and Spanish mahogany for those of resonant cypress, cedar and pine, and thus obtained a greater power and majesty of tone, while a greater variety of tone was derived by a freer use of the stops. To the three shifting registers of jacks of the octave and first and second unisons, Van Blankenburg's lute stop was added, which by plucking the strings in the lower and medium divisions of the scale, close to the bridge and much nearer the treble, produced a charmingly delicate, reedy tone quality very much like that of the mandolin. Finally, to obtain «crescendo» and «diminuendo,» a swell was introduced, which consisted in gradually raising a hinged portion of the cover with a pedal. This invention of Roger Plenius was probably suggested to him by the nascent pianoforte which appears to have been first made by him in England.

Although references to the pianoforte occur in the correspondence of musical instrument makers during the latter part of the 16th century, as, for example, in the letters written by Hippolito Crica or Paliarmo, dated 27 June and 31 Dec. 1598, and addressed to Alfonso II, Duke of Modena, the first true pianoforte, as now understood by that term, was invented by Bartolommeo Cristofori, a Paduan harpsichord maker, in Florence about 1709. At that time kings and princes well disposed toward music were accustomed to keep large collections of musical instruments to be used in connection with their domestic and courtly festivals, and to keep such instruments in playing order it was necessary to employ men possessing the requisite ability. It is of record that Cristofori was engaged in that capacity by Prince Ferdinand de Medici, and while thus employed invented and produced the pianoforte. The record of this invention is given by the Marchese Scipione Maffee, under the date of 1711, in a description which appeared in the *Giornale dei letterati d'Italia,* a publication conducted by Apostolo Zeno. It gives the information that in 1709 Cristofori had completed four «gravecembali col piano e forte» — keyed psalteries with soft and loud, three of them having the long or harpsichord form. There are two grand pianos still in existence, made by Cristofori, and dated respectively 1720 and 1726. They are of a very perfect construction, and embody all the essentials of piano movement. The first belonged to the Signora Ernesta Mocenni Martelli of Florence, and was acquired by Mrs. J. Crosby Brown of New York in 1895 for presentation to the Metropolitan Museum of Art of that city. It has a compass of four and a half octaves, C–f^3. The second belongs to the Commendatore Alessandro Kraus of Florence. Their actions are similar, and show that Cristofori succeeded in satisfactorily solving the problem of escapement, and had also provided for repetition

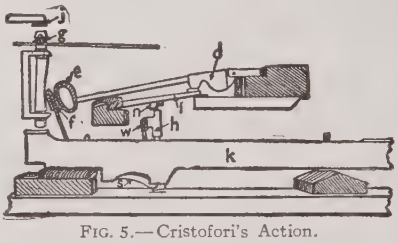

FIG. 5.—Cristofori's Action.

without a double escapement. Fig. 5 is a complete diagram of this action: (k) is the key; (h) the hopper or movable tongue; (n) the notch for the hopper beneath an underhammer or escapement lever (l), which being covered with leather upon the end operates to raise the hammer butt (d); (e) is the hammerhead; (s) the spring regulating the play of the hopper or distance between it and the string and regulated by a small hopper check (w); (f) hammer check; (g) damper, and (j) damper stop. It appears that in this action, Cristofori retained the shallow measure of an Italian harpsichord, and consequently inverted his wrest-plank (the block in which the tuning-pins are held), which had to be much stronger than in the harpsichord, owing to the increased thickness of the strings which were required to stand the impact of the hammers, and attached the strings beneath. The pins pierced the wrest-plank so that the tuning was accomplished harp fashion. His instruments ranged in compass from four to four and a half octaves. The essential features of Cristofori's action were adopted by Gottfried Silbermann, the great organ builder and clavichord maker of Dresden. He made two pianofortes, which he submitted to J. S. Bach, who disapproved of them on account of their weak treble and heavy action. Recognizing that he had not attained the requisite skill to reproduce the excellent quality of his models, he devoted several years to experiments, and finally submitted another to Bach, which met with the great composer's approval. It is a fact, however, that the elder Bach never really adopted the pianoforte, and that all of J. S. Bach's compositions for the clavichord and harpsichord, no less than those for the organ, have to be virtually transcribed in the rendering when transferred to the pianoforte. This fact is very clearly shown in Czerny's edition of the 'Forty-eight Preludes and Fugues.'

The Seven Years' War (1755–62) terminated Saxon pianoforte making, and scattered the workmen, some of whom found their way to England and made a fresh start in the business.

Up to 1760, all pianos had been built in the shape of the modern grand, horizontal or upright; but, between 1760–65, Johann Zumpe, a former workman in Shudi's establishment, introduced the English square piano. The action was sufficient, although almost rudimentary, and contained what was called the "old man's head," a metal pin with a leather knob on the top to raise the hammer, and the "mop-stick" damper raised by a simple jack. The compass was five octaves from F–f³. Zumpe's success was immediate. The instruments sold rapidly, and the form increased in popularity. Other makers started establishments, and in the last decade of the century, London became the centre of the world's pianoforte trade, with not less than 30 square piano-making establishments, English and German, in active operation.

Between 1780 and 1790, John Broadwood recognized the fact that when the string was struck at a certain point, it yielded a fuller tone. He, therefore, adjusted the hammers so as to obtain this result, and also transferred the wrest-plank to the back of the case, and introduced the two pedals — one to raise all of the dampers, and the other to soften the tones by dropping a piece of cloth over the strings. The change in the place of the wrest-plank enabled him to reduce the inordinate length of the unused wire, and also to straighten the keys,

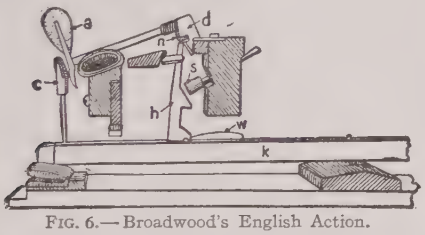

FIG. 6.—Broadwood's English Action.

which had been hitherto left more or less twisted, as in the clavichord, but in connection with the crank damper, he did not get beyond the "old man's head" device that lifted the hammer, and the merit of introducing in the square piano the "hopper" — a jack with a string working in a notch forming the front part of a lever, technically known as the "under-hammer" — belongs to John Geib, who took out a patent for the improvement in 1786, and first applied it to the square pianos he made for Longman and Broderip, music publishers in Cheapside.

Fig. 6 shows the Broadwood grand piano action, commonly known as the "English direct lever action," in which the key (k) on being depressed raises the hopper (h) which strikes in the notch (n) cut in the butt of the hammer (d), the play of the hopper against the notch determining the velocity of the hammer and the individuality of the player's touch; (w) is the wire hopper check; (s) the screw that regulates the lever to determine the distance of the hopper motion; (a) is the hammer-head, and (c) the check which is raised when the key is depressed and arrests the hammer in its fall. It is the first simple contrivance for repetition, that is, for repeating the blow of the hammer before it returns to its original position or equipose. The key not only raises the hopper and check, but also the damper, so as to allow the string forming the note to continue the vibration, and the escapement when raised without impact as depends upon that space between the hammer and the strings, to allow the hammer to clear them under a blow either soft or loud, and thus prevent the strings stifling the vibration before it has had time to become a musical note. This action was invented about 1772, and was further developed and perfected by Broadwood, with the assistance of Backus and Stodart, until it became the best single escapement action.

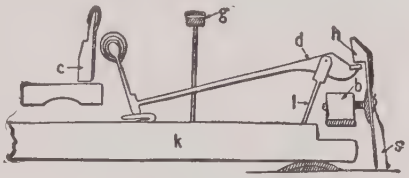

FIG. 7.—Streicher-Viennese Action.

About 1777 the German manufacturers produced another kind of escapement, which was considered favorably by prominent pianists for many years. It was invented by Stein, a pupil of Silbermann, but was carried to its highest state of perfection under the joint efforts of his daughter Nannette and son-in-law, Andreas Streicher, about 1794. Fig. 7 shows the construction of this action: (k) is the key, (h) the hopper, (s) the hopper spring, (l) the standard in which the hammer butt (d) is centred, (b) the set-off button, (c) the check and (g) the damper. This action differs from the Cristofori (English) action, in that the hammer is directly attached to the rear end of the key itself, instead of being fixed to a lever independent of the key. This arrangement caused a change of axis of the hammer when the key was struck, thus giving the extreme lightness of touch which enabled easier execution and brilliant playing, although less capable than the English of producing its tone varieties. Up to 1777 the French imported their pianos chiefly from England, when Erard (Erhardt), a German pianomaker, produced the first piano made in France. Having been driven to London by the Revolution, he familiarized himself with the English methods, and incorporated the English principles in his first instrument. Subsequently he

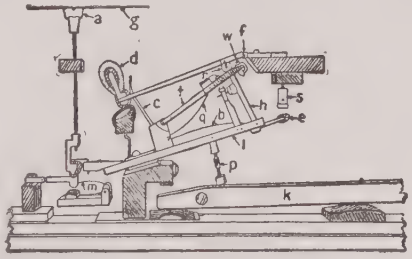

FIG. 8.—Erard's French Action.

adopted the Stein principle, and afterward developed his own action, illustrated by Fig. 8, in which, when the key (k) is depressed, the lever (l) is raised by the pilot (p), and the hopper (h) escapes forward when it has delivered its blow to the roller (r) beneath the hammer fork (f). Similar to the notch of the English action, the roller transmits to the hammer the player's intention and individuality. A prolongation of the hopper forms the escape-

ment lever (e) which controls the set-off from the strings by the screw and button (s). The wire hopper spring (b) maintains the hopper in position, and together with the hammer-head (d) and the check (c), completes the single escapement action. The repetition or second escapement is obtained by the roller resting upon the hinged repetition lever (t) which rises when the wire spring (q) is bent by the depression of the key, the rise of the lever being controlled by the screw (w), which acts on the point of the lever.

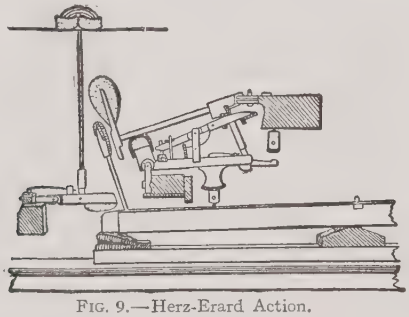

FIG. 9.—Herz-Erard Action.

Under this arrangement, no matter how slowly the key is depressed, the action produces sound, and also enables the hopper to repeat a blow with a partially risen key. The damper (a) is beneath the string (g) and is pushed up by the spring (m). This double escapement action was invented by Sebastian Erard and patented by his nephew, Pierre Erard, in 1821, but did not succeed in obtaining public recognition until after 1835. While not demanding as high a finger movement as the English action, it is uniform in the variety and directness of blow.

The Herz-Erard repetition action shown in Fig. 9 is a simplified form of the Erard action just described. It was first employed in the grand pianos of Henry Herz of Paris, but, owing to its economy and efficiency, has been adopted with slight modifications by many of the most prominent piano-makers. Next to Erard the most prominent piano manufacture in France was Pape, a native of Hanover. In 1827 he invented a down-striking action, of which the mechanism was above the strings. During the latter part of the 18th century the desire to save space originated the idea of making musical instruments of this class in an upright form. The first attempts were merely to turn the horizontal pianos, spinets and harpsichords into a vertical position on a stand. In the year 1800 John Isaac Hawkins, an Englishman, living in Philadelphia, Pa., invented the first genuine upright piano and patented it in the United States and England. He called it the Portable Grand Pianoforte, and it is remarkable as containing most of the features characteristic to the modern upright. The idea was further developed and improved by Southwell in 1807, who produced the now obsolete but beautiful toned "Cabinet," and by Wornum, who produced a low upright with diagonal strings, in 1811, and one with vertical strings in 1813.

Fig. 10 shows the Wornum upright piano action, as made by Broadwood: (k) is the key, (b) the hopper, (d) the hammer-butt, holding the shank of the hammer-head (e); (c) is the check, (f) the damper, (i) the set-off button, (l) the spiral hopper spring invented by Bord, (m) the pilot, employed to raise the hopper and its crank to the height required for their service, and the tape (n), which, being tightened by the rise of the hammer when the key is struck, pulls the hammer back when the key returns and thus assists the repetition. Because of the small floor space occupied the upright piano became the instrument for the million, but it can never be the choice of the artist, because it smothers the vibrations, which can be brought out fully in a grand piano.

A modern piano consists of the following parts: (1) The "case," made of rosewood, mahogany, walnut, cherry, maple or other hard wood, and, according to its form, classified as grand, square or upright. The grand pianos are triangular in body and are built in various sizes, from the full concert grand, 8 feet 10 inches in length, to the baby grand, six feet long, and adapted to parlor use. The square form is no longer built, having been entirely superseded by the upright for use in private houses. The outer side of a piano case is usually veneered over the solid wood. Some makers build their piano cases of material made of several thicknesses of wood, under the supposition that it assists the resonant qualities. Some cases are very elaborately carved and others expensively inlaid. Special instruments have been made costing as high as $50,000. (2) The "frame," now almost universally made of iron or steel, held within the case and inseparable from it. (3) The "string-plate," attached to the rear end of the frame and to which the strings are fastened. (4) The "wrest-plank," attached to the front end of the frame and holding the tuning pins, around which one end of the strings is wound, so that their tension is regulated by turning the pins. The wrest-plank has to be made very solid to ensure the rigidity necessary to withstand the enormous strain of the strings, a tension amounting to from 10 to 20 tons.

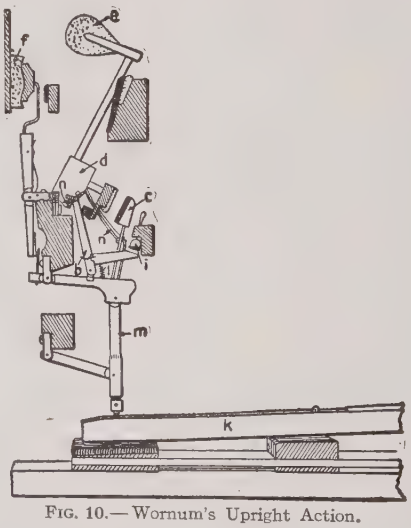

FIG. 10.—Wornum's Upright Action.

(5) The "belly" or "sounding-board," a thin

piece of wood placed under the strings to increase the sound produced by their vibrations. Owing to their small diameter and consequent limited contact with the air, the sound produced by strings vibrating freely is so weak that a resonance factor is necessary. This factor is supplied by the belly upon which hardwood bridges are glued, which transmit the vibrations of the strings to the belly and thus creates sympathetic vibrations of the woody substance so as to adequately increase the sound. The manufacture of sounding-boards is an important branch of the industry and elaborate planing and glueing machinery is utilized.

(6) The "strings," made of steel wire, one end of each being fastened to the string-plate and the other coiled around tuning-pins in the wrest-plank. They increase in length and thickness from the treble to the bass. In the bass, in order to make the rate of vibration slower, they are over-spun or wound around with fine copper or mixed-metal wire. For the lowest tones (A_3–F_2) only one wire is employed; for each tone (G_2–C) two strings; and above that, three strings. One of the most remarkable differences between the modern and old pianos is due to the vast increase in the tensile strength of piano wire drawn under modern methods. The breaking strength of English piano wire ranges from 225 pounds for No. 12 music, 0.029 inch diameter, to 650 pounds for No. 22, 0.052 inch diameter; giving an ultimate tensile strength of 340,000 pounds to the square inch, about five times that of the best old hand-drawn wire.

(7) The "actions," the principal varieties of which have already been carefully described, and which consist of the entire mechanical device by which the hammers are propelled against the strings, including the keyboard and its row of keys, which are manipulated by the fingers. The keyboard of a modern piano has a compass of seven octaves, A–A, or seven octaves and a minor third, A–C, the extreme notes of which are very near the limits of the power of the average human ear to distinguish musical sounds. Cristofori's pianos were four-octave instruments. The keys corresponding to the natural tones and called "naturals" are made of ivory, and those corresponding to the chromatically altered notes and called "sharps" are made of ebony. They are shorter than the naturals and are raised above them. When a key is pressed down its rear end rises and lifts the "jack," which throws the hammer against the strings. The hammers are attached to shanks of light wood, such as pear wood, hickory or white beech, sufficiently tenacious not to fracture under the hardest blow, and yet elastic enough to rebound. The wooden hammer-head is covered with felt, of compressed sheep's wool, cut from one piece, and increasing in thickness from treble to bass. The texture of the felt should be neither too hard nor too soft. A hammer with a hard surface leaves the strings immediately after contact with it and allows the very dissonant upper partial tones to run their course, while a hammer with a soft surface clings slightly to the string, or at least long enough to damp such discordant partials. Simultaneously with the throw of the hammer the "damper" is raised, thus allowing the string to vibrate freely, but by a "check" which prevents its rebound the damper remains raised as long as the key is pressed down and the string continues to vibrate.

(8) The "pedals," a set of levers, usually two in number, which are pressed down by the feet. They are called the "piano" and "forte" pedals; some makers add a third called a tone-sustaining pedal. The left foot presses upon the "piano" or soft pedal, which either throws all of the hammers nearer to the strings so that the striking distance is lessened by one-half, or by shifting the keyboard action bodily, removes the stroke of the hammer from three to two strings, one being left unstruck, but not silent, since it vibrates in sympathy with the sounding strings with which it is in tune. This sympathetic vibration gives a beautiful æolian tone quality that has been recognized by modern composers from Chopin to Liszt as of much advantage. The "forte" or loud pedal is pressed by the right foot and raises all the dampers so that the strings struck continue to vibrate even after the keys are released. The "tone-sustaining" pedal, although not invented by the Steinways, is often found in their grand pianos. It is an arrangement that, instead of raising all the dampers, allows the player to prolong any note or group of notes by keeping raised only such dampers as are raised by the keys when the pedal is down. In many upright pianos a soft pedal (Celeste) is applied by mechanically interposing a strip of thin felt between the hammers and the strings, thus materially diminishing the sound, and affording a great convenience in practising.

The earliest compositions for the pianoforte appear in a volume entitled 'Sonate da Cimbalo di Piano e Forte, detto volgarmente di Martellatti.' Dedicato a Sua Altezza Reale. Il serenissimo D. Antonio Infante Di Portogallo, e Composto da Lodovico Guistini di Pistoia. Opera Prima, Firenzi, 1732, the year after Cristofori died. The first compositions which showed a technique characteristic of the pianoforte are the three sonatas by Muzio Clementi, published in 1773. From that date the composers studied the new instrument and employed the proper technique, with the result, as in the case of Beethoven's magnificent pianoforte compositions, that they went beyond the capabilities of the instruments of that time, and stimulated the piano-makers to increase both the compass and the power of the instruments. Increase in the power of tone demanded strings of greater thickness, while the extension of scale called for an increased number of strings, and, consequently, an enormous increase in the tension strain on the frame. These conditions led to the use of metal for frames, beginning with the hollow metal tube framing patented by Allen and Thom in 1820, followed by the cast-iron frame of Babcock of Boston, in 1825, and the improvements of Jonas Chickering, who introduced the full iron frame in 1837. Then came Steinway and Sons, who in 1859 introduced the overstrung scale, permitting a much larger number of wires in a small space; thus the modern pianoforte was developed to its present state of perfection and power (see Fig. 11).

Some of the men who have made the piano history of America are Jonas Chickering, the pioneer, whose place in the trade was later filled by Thomas E. and C. Frank Chickering; George and Francis Bacon; James A. Gray,

William Boardman, A. H. McPhail, E. N. Scherr, Henry Lindeman, H. C. Schomacker, Ernest Knabe, Henry Hazleton, Hugh Hardman, Napoleon J. Haines, Albery Weber, Henry E. Steinweg (later Steinway), Charles, Henry and C. F. Theodore Steinway, William and Albert Steinway, T. A. Heintzmann, F. G. Smith, Myron A. Decker, Hugo Sohmer, Frederick Mathushek, William E. Wheelock, Simon Krakauer, W. B. and H. B. Tremaine, Edwin S. Votey, W. W. Kimball, Edwin S. Conway, Rudolph Wurlitzer, etc.

An important modern invention is the æolian attachment, by which a current of air is directed against the strings to reinforce the vibrations. Considerable increase in the volume and duration of the tone is thus obtained. Of course the device was not available until it became customary to use a small motor or a bellows for power. Another invention for obtaining an æolian effect was brought out in 1891 by Eisemann of Berlin, who introduced electromagnets placed close to the strings. The pressing of any of the keys closed electric curcuits, energizing the appropriate magnets and enhancing and sustaining the vibrations of the notes affected. This device had the novel effect of altering the tone of the piano so that the strings gave sounds resembling harp strings.

Of devices embodying dumb keyboards for practising purposes, the "digitorium' or dumb piano, consisting of a portable box equipped with five keys supported on springs, and the "practice clavier" invented by Virgil of New York in 1883, are the modern representatives of a very old idea. The use of the former has been severely condemned by good musicians; but the latter, which possesses a complete keyboard, is of great use in the practice of a legato touch. The mechanical arrangement affords two audible clicks — one when a key is pressed down and the other when it is released, so that the only observation required of the performer is to note that the two clicks caused by the depression of one key and the release of the next coincide. The apparatus may be so adjusted that the action can be regulated at will, from the lightest, two ounces, pianoforte touch, up to a touch exerting a pressure of 20 ounces. Its use is of great advantage in acquiring strength of the fingers and for purely technical exercises.

The mechanical or automatic piano had its origin in an adaptation of the perforated cards of a Jacquard loom, in which the holes are positioned so as to direct the disposition of the threads in a pattern. The earlier patents for the use of this principle for playing the keys of a piano were by Seytre of France, Bain of Scotland and Pape of Paris. The principle is applied by means of a continuous roll of stout paper in which are holes or perforations positioned so that as the roll is unwound air is permitted to pass through the holes to the tubes indicated, thus being directed to operate the right piano keys at the correct time. Electromagnets have also been employed to make the connections between the perforated roll and the keys, but as a rule the modern automatic pianos and player-pianos depend on a bellows-pump and the resulting air-pressure or suction to strike the keys and operate the instrument.

The first markedly successful machine involving this principle was made as an attachment to a piano and named the "Pianola" (see Fig. 12). This is placed in the front of the piano so that its "pneumatic fingers," usually 65 in number, will strike the keys of that instrument. It is operated by means of pedals, levers, the tempo regulator, pneumatic action and perforated music rolls. It possesses the great advantage in that the player can exercise a certain control over expressive interpretation of musical work, by automatically developing the phrasing indicated in the score, which is to music what punctuation is to literary work. To this capacity is added that of fine dynamic shading and variations in tempo, productive of tone-color and accent. The touch of the pianola is produced by the action of jets of compressed air, which act on the keys of the piano, and is as nearly like that of human fingers as it is possible to obtain by mechanical means. The air being exhausted with greater or less suddenness furnishes a pliant and resilient quality that

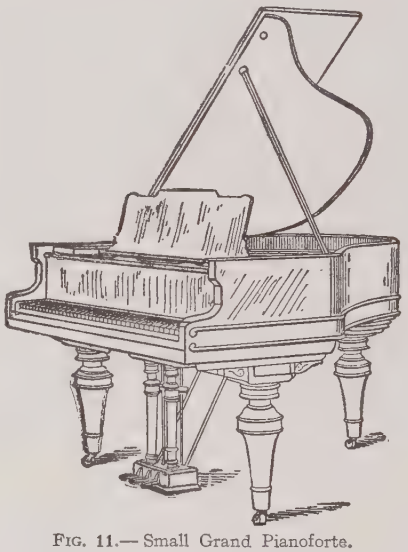

Fig. 11.— Small Grand Pianoforte.

affords a range — from the soft velvety legato to a blow as powerful as that exerted by Liszt or Rubinstein. The tempo-indicator is used in accordance with the system of markings on the perforated roll music, so that the piece is played exactly in the time intended by the composer. The time-shading of the various passages being prescribed by the metronome, perfect time is obtained by simply moving the tempo-lever back and forth upon a dial marked from 0 to 130, to accelerate or retard the movement. It is also equipped with a forte-lever, to still further sustain and control expression.

The immense sale of the pianola led piano-makers generally to seek to incorporate its principles into their machines, and hence arose the player-piano, which type of instrument has so taken the market, that the demand for an old-style hand-played upright is rapidly reducing. Each of the leading manufacturers brought out some form of player-piano that would play music furnished in the roll, and at first each gave a special name to his product. But as there was little difference in the mechanisms, the public came to pay less attention to the trade names, and all these instruments have

come to be classed as player-pianos. After a time it became obvious that it was to the interest of the trade to have a standard width of music roll, so that music could be run on any player-piano, and a trade agreement was entered into to that effect between leading manufacturers. The typical player-piano has a bellows, operated usually by foot-pedals like those of parlor-organs; also a compensating or equalizing device to govern the air-pressure, which is very necessary; a series of air-tubes to which a current is admitted when a perforation of the traveling music-roll uncovers the desired valve; a motor (which may be based on the bellows-power) for moving the paper roll, and a tracker-mechanism for utilizing the air-pressure or vacuum, to strike the keys of the piano itself. There are also controlling levers for regulating the time, by allowing the roll to move slower or faster; also for re-

FIG. 12.—Pianola in operation.

winding and for producing the expression. Large player-pianos are made on this principle and fitted with electric motors for use in furnishing automatic music in "movie" theatres, on shipboard, etc., these being commonly called automatic pianos.

According to the United States Census of Manufactures for 1939 there were made in that year in the United States a total of 111,245 pianos of all sorts, valued at $18,031,038, compared with 103,110 pianos and a value of $19,567,879 in 1937. Of the pianos manufactured in 1939, 18,658 with a value of $2,380,283 were uprights; 29,847, with a value of $4,453,840, were vertical or console models with conventional action; 46,700, with a value of $6,451,342, were console models, flat top, drop action. In 1939, grand pianos under 5 feet in length were made to the number of 8,359 with a value of $1,945,703; grands from 5 to 6 feet in length numbered 7,230 with a value of $2,567,684; and grands over 6 feet in length numbered 451 with a value of $232,186. In the same year the value of piano parts and materials was $4,773,413, of which $1,400,534 was the value of actions and strings for pianos, and $3,372,879 the value of other parts and materials. The decline in the industry, which set in in the 20's was arrested in the late 30's.

According to the 1939 census, there were in the United States 35 piano factories in operation (160 in 1923), giving employment to 5,311 workers (22,208 in 1923); who were paid $6,123,348 in wages ($30,679,000 in 1923). The cost of the materials used in the industry was $10,124,236 ($54,179,000 in 1923), and the value of the product was $20,493,110 ($111,160,000 in 1923).

PIANOFORTE INSTRUCTION, Methods of. The word "method," as applied to pianoforte instruction, may be used in a double sense. In the first place it may refer to the current collections of exercises and pieces which are used for the teaching of beginners; in the second place it may refer to modes or principles of instruction. We shall use the word only in the broader sense. To be sure, the two meanings overlap to a considerable degree. A plan of instruction is generally embodied in books intended for the guidance of pupils, and collections of the kind mentioned are likely to contain suggestions of a pedagogic nature in addition to the material they offer for practice. Methods have been numerous, and it cannot be our purpose to go into a detailed enumeration and consideration of them. Nor will it be necessary. For most of the systems of former days have been superseded by later ones, so that an examination of the former would have only a remote, historic interest. Among the more important systems of the first half of the 19th century were those of Logier, Kalkbrenner and Czerny. A peculiarity of the Logier method was its employment of the mechanical device known as the chiroplast; likewise the simultaneous teaching of many pupils. Kalkbrenner used a modified form of the chiroplast, called the hand-guide. Czerny was the pedagogue who especially promoted the technical side of piano playing. Many of his études are classical and are still in use among teachers. Plaidy had the same end in view in his well-known 'Technical Studies.' It is peculiar that the individuals in whom pianoforte virtuosity found its culmination — including Liszt, Tausig, Bülow and Rubinstein — should have given us no methods of instruction. Tausig, to be sure, left a collection of valuable studies, a feature of which is the persistent use of certain fingerings, unobstructed by the presence of black keys. And Bülow has likewise embodied some novel ideas on fingering in the editions flowing from his pen. But nothing approaching a system or method was left by any of these men. The more im-

portant methods of recent times are those of Köhler, Deppe, Leschetizky, Mason and Virgil — the two latter being the product of American thought. The Köhler method is careful and betrays great pedagogic ability; but it is somewhat dry and lacks important features which are the result of more recent insight. Deppe's method lays great stress on ease and freedom of movement and advocates co-operation of the arm in playing. His maxim is: "If it looks well, it is right." Leschetizky has been famous as the teacher of a great number of eminent pianists. In consequence his system has gained wide celebrity. An examination of the same, however, as outlined by some of his assistants (Brée, Prentner), fails to reveal any startling innovations and so we are inclined to attribute his success to personal qualities as a teacher rather than to peculiar secrets of system. Mr. Mason may be regarded as the Nestor of American teacher-virtuosos. He published a method entitled 'Touch and Technic,' which is very popular on this side of the Atlantic. Opposed to the stiff finger and wrist playing of former days, he aims particularly at beauty of touch. Like Deppe, he lays stress on arm movements, his analysis of the same being especially illuminating. He likewise developed an ingenious method of practising scales and arpeggios in various rhythms and tempos. The Virgil method is unique inasmuch as it makes use of the dumb piano called the Practice Clavier. Tone is here replaced by clicks, which can be produced both by the up and down action of the keys. Likewise the force necessary to depress the keys is subject to regulation. Special printed instructions of a very detailed nature are supplied for the guidance of teachers and pupils.

In general, the tendency of modern instruction has been toward freer and more natural movements and specifically toward a more liberal use of the arm. Playing in the older days was comparatively stiff. It proceeded mainly from the fingers and wrist and the members not directly involved were supposed to be held quiet. This has been changed of late: the old hammer-like touch of the fingers is having its supremacy disputed by touches that depend more on pressure, while the arm and forearm are constantly being brought into play. Even the time-honored motion of the thumb under the palm of the hand, in performing scales and arpeggios, is no longer insisted on so rigorously, and deft arm-movements are coming into the foreground.

Among the foremost innovators in this movement is Rudolf M. Breithaupt. He has published a voluminous treatise entitled 'Die natürliche Klaviertechnik,' which is searching in its analysis and replete with excellent suggestions. Among other things, Breithaupt abandons the traditional wrist stroke, and his playing of scales is accomplished by means of hand and forearm movements, with the minimum passing under of the thumb.

While this is not the place to pronounce judgment on methods, we may refer to the consensus of modern opinion in favor of freer and more natural movements and liberal co-operation of the arm. The results which have been arrived at are based on careful analysis and seem destined to become permanent. Among the future advances to be expected in the field under consideration is the application thereto of psychological methods. Hitherto very little has been accomplished in this direction. Yet there is hardly a field which is more favorable to the work of the psychologist. The exact determination of the best playing motions, the regulation of practice hours, the testing of pupils for musical talent — these are but a few of the many things with which psychology would be competent to deal. There is no doubt that this work will soon be taken up. And the results will be shown in heightened efficiency on the part of the teacher and greater progress on the part of the pupil.

ALBERT GEHRING,
Author of 'The Appreciation of Music,' etc.

PIANOLAS. See PIANOFORTE.

PIARISTS, members of a religious order, known as "Patres Piarum Scholarum," and devoted especially to the education of the young. The order was founded in 1597 by a Spanish nobleman, Joseph Calasanza (Saint Joseph Calasanctius) (1556–1648). In 1621 the order was approved of by Gregory XV, and endowed by Innocent XII with all the privileges of a mendicant order (1690). Much of the work of the Piarists was accomplished in Poland and Austria, where there are still flourishing several Piarist schools. The members of the order number some 2,000 and they manage about 200 educational establishments. (See ORDERS, RELIGIOUS). Consult Heimbucher, M., 'Die Orden und Kongregationen der Katholischen Kirche' (Paderborn 1907); 'Ordinis Clericorum Regularium Pauperum Matris Dei Scholarum Piarum Catalogus Generalis' (Rome 1909); Seyffert, E. J. A., 'Ordensregeln der Piaristen' (2 vols., Halle 1783).

PIATT, pī'at, **Donn,** American lawyer and journalist: b. Cincinnati, Ohio, 29 June 1819; d. Cleveland, Ohio, 12 Nov. 1891. He was educated at the Athenæum, now Saint Xavier's College, Cincinnati, and by private tutors. Though he studied law with his father for a number of years and became a partner in his older brother's law firm, he devoted much of his time during these years to writing for newspapers. In 1852 he was appointed judge of the Court of Common Pleas of Hamilton County, Ohio. On account of the failing health of his wife — he had married in 1847 — he went to France in the summer of 1853 and settled in Paris, from which city he did considerable writing for American and English newspapers on current events. In April 1854 he was appointed secretary of legation at Paris by President Pierce, acting as chargé-d'affaires whenever his chief was absent or ill and acquitting himself in this responsible position with great credit. In 1855 he returned to the United States and again took up his former interests, politics and journalism. He was an active supporter of Lincoln and Fremont. On the outbreak of the Civil War he entered the Union army as a private, attained the rank of colonel and was assistant adjutant-general and chief of staff of General Schenck. He resigned in 1864, and in the fall of 1865 was elected as a Republican member of the Ohio house of representatives. In 1868 he accepted the position of Washington correspondent of the Cincinnati *Commercial.* In March 1871 he founded and began to edit the Washington *Capital.* In 1880

he decided to retire to his old home in Ohio, Mac-o-chee, about 100 miles north of Cincinnati. He did not dispose of his financial interest in the *Capital,* however, until 1890. During the years of his retirement he devoted himself to literature and farming. He wrote 'The Memoirs of the Men Who Saved the Union' (Chicago 1887); 'The Lone Grave of the Shenandoah and Other Tales' (Chicago 1888); 'Poems and Plays' (Cincinnati 1893); 'Sunday Meditations' (Cincinnati n. d.); with H. V. Boynton, 'General George H. Thomas' (Cincinnati 1893). Consult Miller, C. G., 'Donn Piatt: His Work and His Ways' (Cincinnati 1893).

PIATT, John James, American poet: b. James' Mill, Dearborn County, Ind., 1 March 1835; d. Cincinnati, Ohio, 16 Feb. 1917. He was educated at Capitol University (Columbus, Ohio) and Kenyon College (Gambier, Ohio), was clerk in the United States Treasury Department in 1861–67, librarian of the United States House of Representatives 1871–75, consul at Cork, Ireland, in 1882–93 and consul at Dublin April–September 1893. In 1868–69 he was editorially connected with the Cincinnati *Chronicle* and in 1869–78 with the Cincinnati *Commercial.* He attained considerable recognition among American minor poets. His works include 'Poems by Two Friends' (1860), with W. D. Howells; 'The Nests at Washington' (New York 1864), and 'The Children Out-of-Doors: A Book of Verses by Two in One House' (Cincinnati 1885), with S. M. B. Piatt (q.v.); 'Poems in Sunshine and Firelight' (Cincinnati 1866); 'Western Windows and Other Poems' (New York 1869); 'The Pioneer's Chimney, etc.' (Cincinnati 1871); 'Landmarks, The Lost Farm and Other Poems' (New York 1872); 'Poems of House and Home' (Boston 1879); 'Penciled Fly-Leaves' (Cincinnati 1880); 'At the Holy Well' (Dublin 1887); 'Idyls and Lyrics of the Ohio Valley' (Boston 1888); 'A Book of Gold' (1889); 'The Lost Hunting Ground, etc.' (London 1893); 'Little New-World Idyls' (New York 1893); 'The Ghost's Entry and Other Poems' (1895); 'A Return to Paradise.' He also edited: 'The Poems of George D. Prentice' (Cincinnati 1876); 'The Union of American Poetry and Art' (Cincinnati 1880); 'The Hesperian Tree, An Annual of the Ohio Valley' (Cincinnati 1900–03). Consult Howells, W. D., 'John James Piatt' (in *Harper's Magazine,* Vol. CXXXV, p. 291, New York 1917).

PIATT, Sarah Morgan Bryan, American poet: b. Lexington, Ky., 11 Aug. 1836; d. 24 Dec. 1919. She was graduated from Henry Female College, New Castle, Ky.; and in 1861 married J. J. Piatt (q.v.). Her first poems were published in the Louisville, Ky., *Journal.* She spent many years in Ireland, where her husband acted as United States consul at Cork and Dublin, with whom she published 'The Nests at Washington and Other Poems' (New York 1864); and 'The Children Out-of-Doors' (Cincinnati 1885). Her other works include 'A Woman's Poems' (Boston 1871); 'That New World and Other Poems' (Boston 1876); 'Poems, in Company with Children' (Boston 1877); 'Dramatic Persons and Moods, with Other Poems' (Boston 1880); 'An Irish Garland' (Boston 1885); 'Selected Poems' (Boston 1885); 'In Primrose Time: A New Irish Garland' (Boston 1886); 'A Voyage to the Fortunate Isles and Other Poems' (Boston 1886); 'Child's World Ballads' (Cincinnati 1887); 'The Witch in the Glass' (1889); 'An Irish Wild Flower, etc.' (New York 1891); 'An Enchanted Castle' (New York 1893); 'Completed Poems' (2 vols., New York 1894); 'Child's World Ballads, Second Series' (Cincinnati 1895).

PIAUHY, pē-ow-ē', or **PIAUHI,** a state of northern Brazil, bounded on the north by the Atlantic (for only 20.5 miles), on the east by Ceará and Pernambuco, on the south by Bahia and on the west of Maranhão, the boundary being the Parnahyba River, into which all the streams of the state flow. The only one of any importance is the Piauhy, which gives its name to the state, rises in a range also called Piauhy, about 350 miles from its junction with the Parnahyba. The sandy, low-lying coast has no harbor, and the ports on the delta of the Parnahyba River cannot accommodate vessels of deep draught. The state extends inland for 560 miles and its highest elevation is 3,300 feet—in the mountain range along the southeasterly border. The most of the state consists of high, rolling plains. The area of the state is 245,582 square miles. The climate is hot and dry, but healthful. Severe autumnal droughts are common. Agriculture is but little developed, although both soil and climate are favorable. The main natural resources are forest products, particularly the oil of the babassú palm. The chief industry is the raising of livestock—cattle, sheep, goats and swine, with a comparatively few horses and mules. The hides and dried meats of these animals form the principal exports. Other exports are wax, cotton and tobacco. The governor is chosen by popular vote for a four-year term. There are 24 members of the chamber of deputies. The state is divided for administration into 39 municipalities. There is no foreign loan and but a small internal debt. There are fewer than 100 public schools, with about 3,000 pupils all told. As many others attend private schools. There is one high school and a college of agriculture. Therezina, the capital, has 57,500 population; that of the state is about 609,000. This is made up of 28.34 per cent whites; 15.18 per cent Negroes; 20.19 per cent Indians; and 36.29 per cent mestizos. Consult James, H. G., 'Brazil' (New York 1925).

PIAZZA, *in architecture,* a portico, or covered walk, supported by arches. It properly signifies a square, or open place of any shape, in a city, and has derived its architectural meaning from the fact that in warm countries such open places are in very many instances surrounded by covered walks. Consult Matthews, A., 'Piazza' (in *Nation,* Vol. LXVIII, p. 416, New York 1899).

PIAZZI, Giuseppe, joo-sĕp'pĕ pē-ät'sē, Italian astronomer: b. Ponte, Valtellina, Italy, 16 July 1746; d. Naples, Italy, 22 July 1826. He was educated in Milan, Turin and Rome, and appointed professor of mathematics at the University of Malta in 1770, where he remained until its abolition in 1780. In the same year he accepted the chair of mathematics at Palermo, where, through his efforts, an observatory was established in 1789. Previous to its opening he made a journey to England where he established

friendly relations with the English astronomers Maskelyne, Herschel, Vince and Ramsden. At his new observatory he made important investigations, the results of which were published in 1792, and in 1801 he discovered the first of the planetoids known to science, which he named Ceres. Though it was visible for but a short time his observations were sufficient to compute its orbit so that it was found in the following year. In 1803 he completed his first catalogue of the fixed stars, which contained 6,784 stars, and received a prize from the Institute of France at Paris, to which it was dedicated. His second catalogue containing 7,646 was completed in 1814 and also received recognition from the Institute at Paris. This catalogue has been of great and lasting value and Piazzi's observations are now being used in a new computation by modern methods. He also made valuable discoveries concerning comets, and in 1817 was appointed chief director of the government observatory at Naples. His most important work after his catalogue was 'Lezioni elementarii di Astronomia' (2 vols., Palermo 1817). The Kaiserlich-Königliche Sternwarte, Vienna, has published in its 'Annalen' (2 series, Vols. IV–XII, Vienna 1841–51) a collection of his observations under the title 'Piazzis Beobachtungen, 1792–1813.' Consult *Edinburgh Journal of Science* (Vol. VI, p. 193, Edinburgh 1827), containing a list of his works; Grant, R., 'History of Physical Astronomy' (London 1852); Maineri, B. E., 'L'Astronomo G. Piazzi' (Milan 1871).

PICA, a genus of the Crow family; the magpie (q.v.).

PICA, the former name of a size of printing type now known as 12-point. It was used as a base or standard for all type measurement. Six picas square equaled one square inch. It was the double of nonpareil, which is now called 6-point. See also PRINTING. Consult De Vinne, T. L., 'Plain Printing Types' (New York 1900); Legros, L. A., and Grant, J. C., 'Typographical Printing-Surfaces' (London 1916).

PICA, a perverted or morbid appetite for substances unfit for food, or incapable of digestion. It is most common in chlorosis and in pregnant and hysterical women. Some insane persons and idiots are subject to it, introducing into the stomach such articles as string, paper and cocoanut fibre. The perverted appetite causes persons having it to eat, with apparent relish, chalk, slate-pencils, coal, plaster, earth, clay pipes, stones, and even filth. Dirt and clay eating (geophagia) exists not only among savages, but also in certain sections of the civilized world, mainly among the lower classes, although sometimes educated people indulge in it. In the case of an appetite for articles of a repulsive nature the disease is called coprophagy, or dung-eating. Physicians incline to regard the vitiated tendency of the appetite as a neurosis connected with the digestive system. It may in some instances be the outcome of habit resulting from the silly desire for notoriety; it may depend on a disordered condition of the brain; may be caused by bad and insufficient diet and chloroanæmia; by inflammation of the mesentery or "the presence in the duodenum of numerous nematoid parasites." It has been supposed that some of the substances eaten supply a deficiency in some of the ingredients of the ordinary food. Horned cattle and sheep are also subject to pica. Prolonged eating of dirt, clay and other unusual substances usually produces emaciation, a protuberant abdomen and a sallow complexion. Sometimes there are serous effusions and hypertrophied liver and spleen. The treatment consists in removal of the causes and the substitution of proper diet. See BULIMIA.

PICARD, George Henry, American novelist: b. Berea, Ohio, 3 Aug. 1850; d. 7 Oct. 1916. Graduated Baldwin University, Berea, in 1869, and from the Cincinnati Medical College in 1877. He published 'A Matter of Taste' (1887); 'A Mission Flower' (1887); 'Old Boniface' (1881); 'Madame Noel' (1900); 'The Bishop's Niece' (1902). He was also managing editor of the McClure Newspaper Syndicate.

PICARD, Jean, zhŏn pē-kär, French astronomer: b. La Flèche, 21 July 1620; d. Paris, 12 July 1682. He took orders and became prior of Rillé in Anjou. He aided Gassendi in the observation of the solar eclipse of 25 Aug. 1645, and in 1655 succeeded to Gassendi's chair in the Collège de France. In 1666 he became one of the original members of the Academy of Sciences. He was the first to apply the telescope to the measurement of angles; improved instruments and methods; founded the *Connaissance des Temps,* an astronomical annual; and by his efforts secured the establishment of the University of Paris. But his principal achievement was the first exact measurement of a degree of the meridian, made in 1669–71 between Amiens and Malvoisine. In 1671 he made a voyage to the island of Uranienburg in connection with the astronomical observations of Tycho-Brahé. On 11 Jan. 1672 Oldenburg read before the Royal Society of London a letter from Paris describing Picard's method and the length of a degree as determined by him. It is probable that it was Newton's knowledge of this measurement that led him to regard his original conjecture of gravitation as satisfactorily established. (See NEWTON, SIR ISAAC). The following of his works have been published separately: 'Degrè du Meridien, entre Paris et Amiens, etc.' (Paris 1740); 'Measure de la Terre' (Paris 1740); 'Traité de Nivellement, etc.' (Paris 1780). Others of his writings have been published in 'Memoires de l'Académie des Sciences, Institute de France.'

PICARD, Louis Benoit, loo-ē bĕ-nwä, French dramatist: b. Paris, 29 July 1769; d. there, 31 Dec. 1828. He went on the stage and began writing for it at the age of 18, and had his first play, 'Le Badinage Dangereux,' a comedy, accepted in 1789. In 1791 his play 'Encore des Ménechmes' gained for him reputation as a playwright. During the Revolution he acted in several of his plays. In 1800 he became director of the Louvois Theatre. In 1807 he was elected a member of the French Academy. In the same year he was appointed director of the Opera, but gave up this position in 1816 to become director of the Odéon where he continued until 1821. Though not a dramatist of the first class, his plays, comedies in prose and verse, exhibit many pleasing characteristics. His style was easy, his power of invention considerable, his humor unforced, his dialogue very natural. He was a prolific writer, producing 94 comedies and seven novels. In some of the former he was assisted by col-

laborators. His novels were of small importance and added little, if anything, to his literary reputation. Among his best plays are 'Médiocre et Rampant' (1797); 'La Petite Ville' (1801); 'Les Marionettes' (1807); 'L'Intriguant Maladroit' (1820). Part of his works were published in 1812. A full collection of them was published as 'Œuvres de Picard' in 10 volumes (Paris 1821). Various selections have been issued: 'Œuvres Choisies' (New York 1830); 'Théâtre de Picard' (2 vols., Paris 1877); 'Théâtre Choisi de L. B. Picard' (Paris 1881). Many of his plays have been translated into various foreign languages. Only two, however, have been translated in English: 'The Parasite, or the Art to Make One's Fortune' (Philadelphia 1872); 'The Rebound' (trans. by B. H. Clark, New York 1915). Two of his plays — 'Encore des Ménechines' and 'Médiocre et Rampant' — have been translated into German by Schiller, and from his German into English as 'The Nephew as Uncle' (by G. G. Harris, Leipzig 1856; by T. C. Wilkinson, Ipswich 1882); and 'The Parasite, or, the Art to Make One's Fortune' (by F. S. Nysson, Leipzig and New York 1856; by J. S. S. Rothwell, Munich 1859). Of his novels only one has been translated into English as 'The Gil Blas of the Revolution, or, the Confessions of Lawrence Giffard' (3 vols., London 1825). Consult Dawson, J. C., 'La Petite Ville' (New York 1913); Lenient, Ch., 'La Comédie en France au XVIIIe siècle' (2 vols., Paris 1888); 'La Comédie en France au XIXe siècle' (2 vols., Paris 1898).

PICARD, a modification of Beghard; see Béguines; Religious Sects.

PICARDY, France, an ancient province, now included in the department of the Somme and parts of the Pas-de-Calais, Oise and the Aisne. Amiens was the capital of the province. In 1435 Picardy was joined to Burgundy and in 1477 became a part of France. In the Great War of 1914–18 it was the scene of much of the fighting on the western front. The struggle initiated with the great offensive of the Germans on 21 March 1918 is known as the battle of Picardy.

PICARIÆ, a group of families of birds, variously limited by ornithological systematists. In its later significance, as established by Nitsch (1820) and substantially adopted by Sclater and the more recent writers, it included the rollers, hoopers, kingfishers, cuckoos, parrots, trogons, woodpeckers, nightjars, owls, swifts, humming-birds and their immediate allies, which consequently are known as «picarian» birds. The still more modern group *Coraciiformes* nearly conforms with it but omits the parrots and cuckoos. The group embraces more than 1,800 species, mainly tropical — most of the families being exclusively so. The group is fully discussed by Stejneger, 'Standard Natural History' (Vol. IV, 1885), and by Evans, 'Cambridge Natural History' (Vol. IX, 1900).

PICASSO, pē-käs'sō, **Pablo,** Spanish painter and sculptor: b. Malaga, 1881. Picasso is of the post-impressionist school and is famed as the founder of cubism. While eminent as a technician he has ever sought the psychical in form rather than the physical and regards color only as to its light effects. His paintings and sculptures were exhibited at the Grafton Galleries, London, in 1912, and at the International Exhibition of Modern Art in New York in 1913. Consult Huneker, J. G., 'The Pathos of Distance' (New York 1913).

PICAYUNE, pĭk-ą-yoon', a name derived from the Carib language and used in Louisiana for a small coin worth six and one-quarter cents, current in the United States before 1857 and known in different States by various names (fourpence, fippence, fip, sixpence, etc.). The word picayune has long been used, especially in the Southern States, in a slang sense to indicate a person or thing of slight value or small importance.

PICCADILLY, pĭk'ą-dĭl-ĭ, in London, a famous street extending for a mile between the Haymarket and Hyde Park corner. At its northern end is an open space known as Piccadilly Circus. Its western half is flanked on the south by the Green Park. In one part of Piccadilly are many fashionable residences and clubs, while another portion contains many handsome shops and stores. Many articles of wearing apparel have been named after Piccadilly, from having been first offered for sale by haberdashers in this thoroughfare. Indeed, it is claimed that the very name of the street has a connection with this trade, though its origin is not absolutely established. About 1623 there was a Pickadilly Hall at the northeast corner of Haymarket and it is surmised that the owner of it had acquired his fortune by the sale of pickadillies, by which name the hems or collars worn with the costumes in vogue at the beginning of the 17th century were known. In its long history Piccadilly has seen many changes. In 1902 part of it was considerably widened. In spite of the fact that some of its historical houses have had to give place to improvement at various times, there are still many buildings left which possess great historical interest. Amongst these are Saint James's Church, built by Wren in 1682–84; Burlington House, part of which dates back to 1695, and which now houses the Royal Society and many other scientific bodies as well as the Royal Academy of Arts; Devonshire House; Apsley House, the residence of the Duke of Wellington. At 139 Piccadilly Lord Byron passed part of his married life and his only daughter was born there. Of more modern houses there are the Museum of Geology; Piccadilly Hotel; Royal Institute of Painters in Water Color; Prince's Restaurant; the Albany Chambers, long residence of many famous English writers; the Burlington Arcade, the home of many fashionable shops. Among the clubs located in Piccadilly are the Naval and Military, formerly the house of Lord Palmerstone, Junior Naval and Military, Badminton, Saint James's, Savile, Junior Athenæum, Cavalry and Lyceum. Consult Baker, H. B., 'Stories of the Streets of London' (London 1899); Besant, Sir Walter, 'London of the 18th Century' (London 1902); 'London of the 19th Century' (ib. 1909); 'North of the Thames' (ib. 1911); Broemel, P. PICCINNI, pēt-chē'nē, **Niccolo,** Italian musical composer: b. Bari, Italy, 16 Jan. 1728; d. Passy, near Paris, France, 7 May 1800. He studied at the Conservatory of San Onofrio at Naples and began to compose comic and serious operas, chiefly for the stages of Rome and Naples, with such success that for many years he was without a rival in Italy. In 1776 he accepted an invitation from the French court and went to Paris. There he brought out the 'Roland of Quinault' (1778), which, notwithstanding the opposition of Gluck (q.v.) and his friends, was successful. Although Gluck and Piccinni were personally reconciled, yet the war between their respective admirers continued and in order to compare their merits, the two rivals composed the same subject, 'Iphigenia in Tauris'; in this contest Gluck had the advantage. Piccinni was appointed teacher of vocal music in the Royal Singing School in 1784, but the Revolution deprived him of his appointments and he returned to Naples. At first he was well received by the king, who granted him a pension. But before long he was, though without cause, suspected to hold revolutionary views. He was deprived of his pension and finally, though not actually sent to jail, restrained under arrest at his own house. In 1798, however, friends succeeded in gaining him permission to return to Paris. Though he was received there with much kindness and was granted a small pension, the irregular payment of the latter caused him frequent and serious financial embarrassment. His health, too, failed and he died in his 73d year as the result of a stroke of paralysis at Passy where he had gone in the hope to recover his health. His great success is now difficult to understand. He was very conservative, possessed little originality, but withal was an accomplished and scholarly composer of pleasing music, which was always quite correct. He was a very prolific worker and in the period of 40 years, from 1754–94, he composed 139 operatic works. His native town has honored his memory by erecting a statue in one of its most prominent streets. Consult Cametti, A., 'Saggio Cronologico (1754–94) delle Opere Teatrali di Niccolò Piccinni' (in 'Rivista Musicale Italiana,' Vol. VIII, pp. 75–100); Ginguené, P. L., 'Notice sur la Vie et les ouvrages de N. Piccinni' (Paris 1800); Le Brisoys Desnoiresterres, G., 'La Musique Française au XVIIIe siècle. Gluck et Piccinni. 1774–1800' (Paris 1872); Longo, A., 'Gluck e Piccinni' (in 'Soc. Reale di Napoli. Reale Accad. di Archeologia, Letters e Belle Arti,' N. S., Vol. V, pp. 311–332, Naples 1917); Thoinau, E., 'Notes Bibliographiques sur la Guerre Musicale des Gluckistes et des Piccinnistes' (Paris 1878).

PICCIOLA, pēt'chō-lä ("poor little one"), a story by Saintine (Joseph Xavier Boniface), a French author, born in Paris, 10 July 1798, and who died there, 21 Jan. 1865. It was published in 1836, ran through numerous editions, was translated into many languages and received from the Academy the Montyon prize. The tale is a simple and touching recital of the loving care bestowed by a prisoner of Napoleon's time upon a plant growing between the stones of his cell and from his tender naming of which the sketch takes its title. An infusion of it restores him from dangerous illness and when he is released and leaves, the plant droops and dies.

PICCOLO, a small flute having the same compass as the ordinary orchestral flute, but producing sounds one octave higher than the notes as they are written; it is also called the octave flute. Piccolo is also the name of an organ stop of two feet length giving a piccolo tone.

PICCOLOMINI, pik-kō-lōm'ē-nē, Italian family of Sienna. The two most celebrated members are: 1. Æneas Sylvius Bartholomæus, afterward Pope Pius II. (See Pius II). 2. Octavio, grand-nephew of the first: b. Amalfi, 1599; d. Vienna, 10 Aug. 1656. He served in the armies of the German emperor and became one of the distinguished generals in the Thirty Years' War. He was a favorite of Wallenstein, who entrusted him with a knowledge of his projects, when he purposed to attack the emperor. Nevertheless he made himself the chief instrument of Wallenstein's overthrow, and after the latter's assassination (1634) was rewarded with a portion of his estates. After the battle of Nördlingen (1634), in which the Swedes were greatly weakened, he advanced with Isolani through Würtemberg, over the Main. In the following year he was sent to aid the king of Spain against the French and delivered the Netherlands from the hands of the latter. His further successful campaigns in the Thirty Years' War induced Philip IV of Spain to beg the emperor to allow him to lead the Spanish armies. The request was granted and as a Spanish general Piccolomini again distinguished himself in the Netherlands, against both the French and the Dutch. The king of Spain rewarded him for his services with the duchy of Amalfi. During the victorious advance of the Swedes in 1648 he was recalled by the emperor and appointed, with the title of field-marshal, to the command of

the troops destined to oppose them. His military career was concluded after a short campaign in the same year by the Peace of Westphalia. He is one of the principal characters in Schiller's trilogy of 'Wallenstein,' to the second part of which he gives the title. Consult Weyhe-Eimke, 'Ottavio Piccolomini' (1871).

PICE, pīs, an Indian coin equivalent to three pies. Since 1 April 1927 it has had a fixed value of 0.57 cent, United States money.

PICHEGRU, Charles, shärl pēsh-grü, French general: b. Arbois, department of Jura, 16 Feb. 1761; d. Paris, April 1804. He was for some time a tutor at the College of Brienne, but soon exchanged this profession for that of a soldier and served with a French artillery regiment. He was chosen the commander of a body of volunteers from Besançon to join the Army of the Rhine. He was rapidly advanced, and in October 1793 was appointed general-in-chief of the same army. In 1794 he was selected as the fittest man to command the Army of the North, then beaten and demoralized. He defeated the enemy at Courtrai, Menin, Hoogelede, reduced to subjection Bruges, Ghent, Antwerp, Hertogenbosch, Venloo and Nijmegen, crossed the Maas and the Waal on the ice in the winter of 1794–95, subjugated Holland and entered Amsterdam in January 1795. Then he returned to Paris to enjoy his triumph. He was now at the height of his fame and was honored by the Convention with the title of savior of his country. Soon after he set out to take the command of the army of the Rhine and Moselle, but in this post displayed none of his former energy, and entering into negotiations with the Bourbons was deprived of his command under suspicion of treason (1796). Having secured his election to the Council of Five Hundred, he was chosen its president (March 1797) and became the soul of the party hostile to the Revolution. He was proscribed and transported to Cayenne, but managed to make his escape the year following. In 1803 he was in London, and there he allied himself with George Cadoudal in a conspiracy to assassinate Napoleon. Having gone to Paris for the purpose, he was captured by the police (1804) and committed to the Temple prison, where he was found strangled 5 April. Consult the 'Life' by Bouziers (1870); also Daudet, 'La Conjuration de Pichegru' (1901).

PICHICIAGO, or **PICHY-CIEGO.** See ARMADILLO.

PICHINCHA, pē-chēn'chä, (1) a volcano in Ecuador in the western Cordillera right on the equator northwest of the city of Quito, which it destroyed in 1660 by an eruption. Since then it has been dormant. The mountain has five peaks, the highest measuring 15,918 feet above the sea; the crater is nearly a mile across and is 2,500 feet deep — one of the deepest in the world. (2) A province of Ecuador, including the plateau of Quito and the Andean slopes, named from the volcano. Pichincha is said to signify "boiling mountain." The province is watered by the Perucho, which empties into the Pacific, and by the head-waters of the Napo. Area, 6,218 square miles; pop. (est.) 326,500. Principal products: sugar, maize, indigo, cotton and fruit. Capital, Quito (q.v.).

PICHON, pē-shôn, **Stéphen (Jean Marie),** French statesman: b. Arnay-le-Duc, 10 Aug. 1857. He received his education at the University of Paris, studied medicine, but soon abandoned it for journalism. In 1880 he became a member of the staff of *La Justice,* a journal owned by Georges Clemenceau. In 1882 Mr. Pichon became a member of the municipal council of Paris, and was several times its secretary. He became a member of the Chamber of Deputies in 1885 and was secretary of the Chamber in 1889–90. In 1894 he was appointed Minister to Haiti, and subsequently served as Minister to Brazil, China and Tunis. In 1905 he was elected senator and in 1906 Clemenceau appointed him Minister of Foreign Affairs. He held the same portfolio in the cabinets of Briand 1910–11 and of Barthou in 1913. On the formation of Clemenceau's War Cabinet, on 16 Nov. 1917, Mr. Pichon again became Minister of Foreign Affairs and also became a member of the War Committee of the Cabinet. He was one of the French delegates to the Peace Conference. Died 18 Sept. 1933.

PICHURIC ACID. See LAURIC ACID.

PICIDÆ, pĭs'ĭ-dē, the family name of the woodpeckers (q.v.); the typical sub-family is *Picinæ;* and the typical genus *Picus.*

PICK, Bernhard, American Lutheran clergyman: b. Kempen, Prussia, 19 Dec. 1842; d. 10 April 1917. He studied in Berlin; graduated, Union Theological Seminary, New York, in 1868. He was ordained in the Presbyterian ministry in that year, and held various important charges, but in 1884 joined the Lutheran denomination, in which he afterward officiated. He was a learned Hebrew and rabbinical scholar, a contributor to McClintock and Strong's Schaff-Herzog and the Jewish encyclopædias; made numerous translations, and published 'Luther as a Hymnist' (1875); 'Historical Sketch of the Jews' (1887); 'The Talmud: what it is and what it says about Jesus and the Christians' (1887); 'The Extra-Canonical Life of Christ' (1903); 'Hymns and Poetry of the Eastern Church' (1908); 'Remains of Gospels and Sayings of Christ' (1908); 'Apocryphal Acts of Paul, Peter, John, Andrew and Thomas' (1909); 'Translations of the Bible' (1913); 'The Cabala' (1913); 'Jesus in the Talmud' (1913). He was a member of the German Oriental Society, Leipzig.

PICKARD, Samuel Thomas, American journalist and biographer: b. Rowley, Mass., 1828; d. 1915. Mr. Pickard acquired the *Transcript* of Portland, Me., in 1852 and continued its editor until 1894. He married a niece of John Greenleaf Whittier, by whom he was made his literary executor. Pickard was also appointed trustee of the Whittier homestead and birthplace. His published works include 'Hawthorne's First Diary' (1897); 'Whittier as a Politician' (1901); 'Whittier Land' (1904); 'Life and Letters of John Greenleaf Whittier' (1907) and numerous monographs and literary articles in newspapers and reviews.

PICKENS, pĭk'ĕnz, **Andrew,** American soldier: b. Paxton, Pa., 19 Sept. 1739; d. Tomassee, S. C., 17 Aug. 1817. He removed with his parents to the Waxhaw Settlement, S. C., in 1752, was engaged in the Cherokee War of 1761, and

at the outbreak of the American Revolution was appointed a captain of militia, from which rank he rose to be brigadier-general. He defeated General Boyd at Kettle Creek in 1779, was engaged in the battle of Stone Ferry in the same year, routed the Cherokees at Tomassee, and in 1781 so distinguished himself at the battle of Cowpens that Congress voted him a sword. He compelled the surrender of the British forts at Augusta, Ga., fought under General Greene in the campaign of Ninety-six, and by a successful expedition against the Cherokees in 1782 gained from them a large strip of territory which later became a part of Georgia. In 1783–94 he was a member of the South Carolina legislature, and in 1793–95 served in Congress. He was a member of the State Constitutional Convention, a commissioner in many important treaties with the Indians, and was again member of the legislature in 1801 and 1812.

PICKENS, Francis Wilkinson, American legislator and diplomat: b. Togadoo, S. C., 7 April 1805; d. Edgefield, S. C., 25 Jan. 1869. He was educated at the South Carolina College, admitted to the bar in 1829 and in 1832 elected to the State legislature. He was a member of the Nullification Party and an advocate of extreme State rights. In 1834–44 he was a member of Congress, from 1858–60 was United States Minister to Russia, and in the latter year was elected governor of South Carolina. He was prominent in the secession movement, demanded the surrender of Fort Sumter and erected the batteries which caused the reduction of that fort. He retired from public life in 1862.

PICKENS, Fort. See Fort Pickens.

PICK'EREL, a small pike (q.v.).

PICKEREL-FROG. See Frog.

PICKERING, pik'ėr-ing, **Charles,** American naturalist and physician, grandson of Timothy Pickering (q.v.): b. Starucca Creek, Pa., 10 Nov. 1805; d. Boston, Mass., 17 March 1878. He was graduated from Harvard in 1823, from its medical department in 1826 and established a practice in Philadelphia. In 1838–42 he was naturalist in the United States Exploring Expedition under Lieut. Charles Wilkes. In 1843–45 he traveled through Egypt, Arabia, East Africa and India, engaged in scientific research. He was a prominent member in the leading scientific societies of America and wrote 'The Races of Man and Their Geographical Distribution' (1848); 'Chronological History of Plants; Man's Record of His Own Existence Illustrated Through Names, Uses and Companionship' (1879); etc.

PICKERING, Edward Charles, American astronomer: b. Boston, Mass., 19 July 1846; d. Cambridge, Mass., 3 Feb. 1919. He was graduated from Harvard in 1865, was instructor in mathematics at the Lawrence Scientific School there in 1865–67, accepted the chair of physics at the Massachusetts Institute of Technology in 1867, where he remained until 1877, after which he was professor of astronomy at Harvard and director of the Harvard Observatory. He established the first physical laboratory in the United States; constructed the first telephone receiver in 1870 and published the 'Elements of Physical Manipulation' (1874–76). In Cambridge he made over 1,400,000 measurements of the light of the stars. Under his direction the endowments of the observatory increased seven-fold; 250,000 photographs of the stars were taken; 70 quarto volumes of annals were published and a station was established in Arequipa, Peru, which supplemented the study for stars in all parts of the sky, and where over 240,000 photographs were taken. He was the recipient of numerous academic honors and was a member of various scientific societies all over the world.

PICKERING, John, American linguist and lexicographer, son of Timothy Pickering (q.v.): b. Salem, Mass., 7 Feb. 1777; d. Boston, Mass., 5 May 1846. He was graduated from Harvard in 1796, studied law, was secretary of the legation at Lisbon in 1797 and in 1799 was private secretary to Rufus King, United States Minister to England. He returned to the United States in 1801 and after admission to the bar practised law in Salem until 1827 and then removed to Boston, where he was city solicitor in 1827–46. He served six terms in the Massachusetts legislature, was president of the American Academy of Science and first president of the American Oriental Society. He possessed a wide knowledge of European, Asian, Egyptian and American Indian languages, and published 'Adoption of a Uniform Orthography for the Indian Languages' (1820); 'Vocabulary of Words and Phrases Peculiar to the United States' (1816); 'A Comprehensive Dictionary of the Greek Language' (1826), etc. Consult Pickering, M. O., 'Life of John Pickering' (1887).

PICKERING, Timothy, American statesman; b. Salem, Mass., 17 July 1745; d. there, 29 Jan. 1829. He was graduated at Harvard in 1763, was admitted to the bar, became register of deeds for Salem County and displayed so great interest in military matters that he was commissioned lieutenant of militia in 1766 and became colonel in 1775. He was a prominent and active patriot, drew up the pamphlet called 'State of the Rights of the Colonists' in 1773, and drafted the Salem protest against the Boston Port Bill. In 1775 he wrote 'An Easy Plan of Discipline for the Militia,' an able manual much used in Massachusetts and for the whole Continental army; and in December 1776 joined the Revolutionary army, meeting Washington in February 1777 and becoming adjutant-general. He fought at Brandywine and Germantown, was quartermaster-general, general 1780–85, and was present at Yorktown. At the close of the war he settled in the Wyoming Valley, where he organized Luzerne County. Pickering concluded a treaty with the Six Nations in 1791, was appointed Postmaster-General in that year and Secretary of War in 1795, founded the United States Military Academy at West Point, and did much for the upbuilding of the navy. He was Secretary of State from December 1795 to May 1800, and after his retirement lived in some destitution on his property in Pennsylvania, whence he returned to Massachusetts. In 1803 he was elected United States senator and in that capacity as in his office of Secretary of State roused popular hatred by his extreme Federalist position. From 1812 to 1814 he was again out of public life, but was elected to Congress in

the latter year and to the Massachusetts Executive Council in 1817. In the second war with England he was a leader of the New England opposition and favored the Hartford Convention (q.v.). Consult the biography by Octavius Pickering, his son, and C. W. Upham (1867–73).

PICKERING, William, English publisher: b. 1796; d. Turnham Green, Middlesex, 27 April 1854. He was apprenticed to a bookseller at 14; was himself bookseller 1820–23; and in 1821 began to publish the famous Diamond Classics in 48mo. Of these there were 24 volumes,, including Shakespeare's Works, Walton's 'Lives' and 'Angler,' Milton's 'Paradise Lost,' the Greek Testament and Homer (in the first diamond Greek type), Horace, Virgil, Catullus, Dante, Tasso and Petrarch, all being printed by Charles Corrall. His other notable reprints were the 'Book of Common Prayer' (1844), Aldine edition of the English poets, etc. He was publisher to Coleridge, Alexander Dyce, Sir Harris Nicolas and others. Pickering introduced the use of cloth covers instead of paper boards, about 1825. He used the Aldine emblem with the motto "Aldi Discip. Anglvs," as well as other emblems. He was financially ruined by standing security for a friend, and died in want.

PICKERING, William Henry, American astronomer: b. Boston, 15 Feb. 1858; d. 17 Jan. 1938. Educated at the Massachusetts Institute of Technology, where he became an instructor. Later he was appointed assistant professor at the Harvard Observatory. He led expeditions to observe the total solar eclipses of 1878 in Colorado, of 1886 in Grenada, British West Indies, of 1889 in California, 1893 in Chile and 1900 in Georgia. In 1890 he established the Southern Station of the Harvard Observatory at Arequipa, Peru, and erected the first telescope and dome for the Lowell Observatory in 1894 at Flagstaff, Ariz. He also established a temporary observatory at Mandeville, Jamaica, British West Indies (1900), and a permanent one there in 1911. While there he devoted his studies to the moon and Mars, indicating that both snow and vegetation are to be found on the former. In 1925 he converted the observatory at Jamaica into a private concern. He published 'Walking Guide to Mount Washington Range' (1882); 'Investigations in Astronomical Photography' (1895); 'Visual Observations of the Moon and Planets' (1900); 'An Atlas of the Moon' (1903); 'The Moon' (1903); 'Lunar and Hawaiian Physical Features Compared' (1906); 'Researches of the Boyden Department' (1908); 'Mars' (1921); four volumes of 'Annals of the Harvard College Observatory'; and many articles, including the 'Reports on Mars' begun in *Popular Astronomy* in 1914 and continuing; No. 43 being issued in 1929.

PICKET, a wooden stake with a sharpened end, or sharpened at both ends, used variously; in the war of 1861–65 often employed to hinder the advance of cavalry. The United States cavalry use a picket-pin, or short iron rod, which is thrust into the ground to hold a picket line or tether, to which the horses are attached for grazing. Also a guard posted in front of an army to give notice of the approach of an enemy; an outlying picket. Also one of a company of striking workmen chosen to watch the place of their late employment and discourage other workmen from accepting employment there.

PICKETING, the practice of placing pickets or strikers on watch over the premises of a factory or other place of employment where there is a strike. See STRIKE.

PICKETT, pĭk'ĕt, **George Edward,** American military officer: b. Richmond, Va., 25 Jan. 1825; d. Norfolk, Va., 30 July 1875. He was graduated from West Point in 1846, served in the Mexican War, especially distinguishing himself at Contreras, Churubusco and Chapultepec, and was promoted to the rank of brevet captain in 1847. He served later on the frontier in Washington Territory, and in 1856 occupied San Juan Island, where he prevented the landing of British troops and received the thanks of Congress for his services. In 1861 he resigned from the Federal army and joined the Confederate forces, becoming major-general in 1862. At Fredericksburg his division held the centre of Lee's line, and at Gettysburg in 1863 he made the gallant assault of Cemetery Ridge, famous as "Pickett's charge." (See GETTYSBURG). He later commanded the department of North Carolina, successfully defended Petersburg in 1864 and performed excellent service at Dinwiddie Court House and Five Forks. He engaged in business in Richmond after the war.

PICKING, Henry Forry, American naval officer: b. Somerset County, Pa., January 1840; d. Charlestown, Mass., 8 Sept. 1899. He was graduated from the United States Naval Academy in 1861 and was assigned to the North Atlantic blockading squadron. He participated in the sinking of the Confederate *Petrel,* was engaged in the *Monitor-Merrimac* engagement, served in the East Gulf and the South Atlantic blockading squadrons, was promoted lieutenant in 1862 and in 1865 placed in command of the *Nahant.* After the war he continued in the service, became rear-admiral in 1898 and died while commandant of the navy yard at Charlestown.

PICKLE WORM, or **PICKLE MOTH,** moth of the Pyralidæ which is numerous in southwestern United States. It bores into cucumbers when they are about half developed and there lives in the larval state. Squash, melon and cantaloupe are also favorite feeding plants for this pest. The sole remedy for its abatement appears to be a thorough spraying with arsenic compounds before the fruit is grown and while the early generation of the pickle worm is feeding on the plant leaves.

PICKLES. Food that has been pickled, especially cucumbers that are preserved in vinegar. They are prepared by first washing in clean water, then soaking for a few days in brine, afterward drying them with a cloth or draining them, and finally putting them into the vessel in which they are intended to be preserved and pouring in boiling vinegar until the vessel is quite full. Before the vinegar is poured in, spices are added. When the vegetables that are to be pickled are naturally soft the vinegar is sometimes poured in cold. To preserve the color of vegetables that are naturally green the best means is to steep vine, cab-

bage, spinach or parsley in the vinegar. In many cases this is effected with much less trouble by boiling the vinegar in copper vessels, and thus forming an acetate of copper, or by directly adding that salt, which is green; but this practice is a very injurious one, as the acetate of copper is poisonous. The vegetables most often pickled are cabbage, cauliflower, gherkins (young cucumbers), French beans, onions, walnuts, mushrooms and nasturtiums. Chile peppers and sweet peppers, olives and capers are the most common kinds of imported pickles, and mangoes are occasionally used. Meats are also sometimes pickled in brine. A diluted acid solution for cleaning metal castings is termed a pickle or pickling solution.

PICKNELL, pĭk'nĕl', **William Lamb,** American painter: b. Hinesburg, Vt., 30 Oct. 1854; d. Marblehead, Mass., 9 Aug. 1897. He went to Europe in 1874, where he studied with George Inness at Rome, and later at the École des Beaux Arts under Gérôme. He settled at Pont Aven, Brittany, where he worked for five years under Robert Wylie and painted 'Route de Concarneau,' a picture that established his position as an artist, won an honorable mention in the Salon of 1880 and now hangs in the Corcoran Art Gallery. His later life was spent in Annisquam, Mass., and France. He was a landscape painter of poetic qualities, with a feeling for atmospheric effects. Subjects found along the coast chiefly attracted him. His pictures are to be found in the galleries of Boston, New York, Brooklyn, Pittsburgh and the Luxembourg, Paris.

PICKWICK PAPERS. "The Posthumous Papers of the Pickwick Club," issued in 20 monthly numbers, began to appear the last of March 1836, and were concluded in November 1837. They were the work of a young man but 25 years old, who had hitherto written nothing more than a group of sketches dealing mainly with London life. A firm of London publishers, Messrs. Chapman and Hall, was then projecting a series of "cockney sporting plates" by Robert Seymour, a rather clever artist. There was to be a club, the members of which were to be sent on hunting and fishing expeditions into the country. Their guns were to go off by accident; fishhooks were to get caught in their hats and trousers; and all these and other misadventures were to be depicted in Seymour's comic plates. At this juncture, Charles Dickens was called in to supply the letterpress — that is, the description necessary to explain the plates and connect them into a sort of picture novel such as was then the fashion. Though protesting that he knew nothing of sport, Dickens nevertheless accepted the commission; he consented to the machinery of a club, and in accordance with the original design sketched Mr. Winkle who aims at a sparrow only to miss it. Seymour dying, other artists took his place; but from the very first Dickens was the master. Only in a few instances did he adjust his narrative to plates that had been prepared for him. He himself led the way with an instalment of his story, and the artist was compelled to illustrate what Dickens had already written. The story thus became the prime source of interest, and the illustrations merely of secondary importance. By this reversal of interest, Dickens transformed, at a stroke, a current type of fiction, consisting mostly of pictures, into a novel of contemporary London life. Simple as the process may appear, others who had tried the plan had all failed. Pierce Egan partially succeeded in his 'Tom and Jerry,' a novel in which the pictures and the letterpress are held in even balance. Dickens, his genius working silently and perhaps unconsciously, won a complete triumph.

To begin with, Dickens had no other aim than to amuse the public month by month. There was in his mind no thought of a novel with a plot to be worked out to a logical conclusion. The first number, of which only 400 copies were bound, awakened only moderate interest. But all was changed with the introduction of Sam Weller in the fifth number; and by the time the fifteenth number was reached, the printer was binding 40,000 copies. People of every class and every age bought or borrowed *Pickwick*. "All the boys and girls," Miss Mitford wrote of Dickens, "talk his fun — the boys in the streets; and yet those who are of the highest taste like it the most." Doctors read the book while riding from patient to patient, and judges read it while juries were deliberating. The fact is, 'Pickwick' was the most amusing burlesque of London life that had ever been written, and it has not since been equalled. Its author was intimately acquainted with all the scenes and persons that he described. He began with the House of Commons, which he turned into the Pickwick Club, with pompous speeches, noisy debates and apologies from gentlemen who wished their abusive remarks to be understood only in "a Pickwickian sense," that is, in a Parliamentary sense. Then he passed on to the law and the courts — pettifoggers who take up civil suits "on spec," to the examination of witnesses, to the judge's charge to the jury and finally to the debtors' prison. All the way along, he drew in careless abandon character after character, running back and forth between the gay and the serious. 'Pickwick' contains more than 150 characters, of whom two stand out conspicuously among Dickens's greatest creations. First there is Pickwick himself, a humorous compound of benevolence and simplicity, shrewdness and common sense, always a gentleman, despite his oddities and follies, with a dash of heroism in the background. And less fantastic, there is Sam Weller — the embodiment of all that is delightful in the London cockney. From the moment he enters the novel until the end, his gaiety pervades the whole up to the climax when he takes the stand for his master in the famous case of Bardell vs. Pickwick, and turns the laughter upon the defendant's counsel Oddly enough, here is a novel which did not set out to be a novel is Dickens's supreme achievement in humor.

WILBUR L. CROSS.

PICO, pē'kō, an island of the Azores (q.v.) group; it is 25 miles long with an area of 175 square miles. It is crossed by a volcanic ridge which terminates in the peak, El Pico, 7,613 feet in height. The island is well wooded and fertile; but earth had to be brought from Fayal to cover or enrich the lava. Now the slopes are covered with vegetation, especially vines,

and the island exports an excellent wine. The chief town is Villa-di-Laguna. Pop. 15,138.

PICO DELLA MIRANDOLA, Giovanni, jō-vän'nē pē'kō dĕl'lä mē-rän'dō-lä, Count of Mirandola, surnamed the "Phœnix," Italian humanist: b. Mirandola, 24 Feb. 1463; d. Florence, 17 Nov. 1494. He undertook the course in canon law at Bologna, but repugnance to the study and an inclination to philosophical and scientific subjects led him to visit the different parts of Italy and France for the purpose of observation and to attend the lectures of the most distinguished professors. In 1484 he went to Florence, where he became a member of the Platonist group known as the "Academy." In 1486 he proposed 900 theses on all subjects, which he declared himself ready to defend, according to the custom of the times, in public. No one ventured to appear against him, and the envious endeavored to implicate him in a charge of heresy. Innocent VIII forbade the reading of the propositions, and Pico withdrew to France. He was absolved, however, from any suspicion of heresy by Alexander VI. Having next applied himself to the study of Biblical literature he published the fruits in 'Heptaplus,' a mystical or cabalistic explanation of the history of the creation, in which he derives Plato's doctrines from Moses. Two years after he publishes a treatise — 'De Ente et Uno' — in which he aimed to unite the opinions of Plato and Aristotle. He was wealthy and gave away most of his property with the intention of becoming an itinerant preacher, but died before carrying out the plan. A collection of his works, almost all in Latin, was published at Venice in 1498. He is introduced as one of the characters in Alfred Austin's drama, 'Savonarola.' Consult Dreydroff, 'Das System des Johannes Pico von Mirandola und Concordia' (1858); Pater, 'Studies in the History of the Renaissance' (1873).

PICO DE TEIDE, pē'kō dā tā'ē-thē. See Teneriffe, Peak of.

PICOLINE, *in chemistry,* a base C_6H_7N, isomeric with aniline and closely related to pyridine, obtained from bone oil, coal-tar, naphtha, etc., the name being derived from Latin, *pix,* pitch, and *oleum,* oil. It is a colorless, mobile, very pungently odorous liquid, with an alkaline reaction and a boiling point of 135° C. One variety is very corrosive, with choking vapors; it quiets the excited nerve centres if used as a hypodermic injection.

PICOT, François, fräṅ-swä pē-kō, French painter: b. Paris, 1786; d. there, 15 March 1868. He was a pupil of Vincent and his early reputation was won by his large picture 'Cupid and Psyche'; which was followed by 'Raphael and La Fornarina'; and an 'Evening Landscape.' His 'Death of Sapphira,' also an early work, is in the church of Saint Severin at Paris. The French government purchased for the Luxembourg Gallery his 'Orestes Sleeping in the Arms of Electra.' He painted a 'Madonna' for the church of Loretto at Paris, and in the Louvre executed two ceiling pictures, 'Egypt and Greece,' and the 'Fall of Pompeii and Herculaneum.' His colossal figure of 'Christ' in the church of Saint Vincent de Paul at Paris is in the Byzantine style. He, however, met with much greater success as a teacher of painting than as a painter.

PICOT, Georges, zhŏrzh pē-kō, French historian and jurist: b. Paris, France, 24 Dec. 1838; d. 1909. He studied law, was appointed a judge in the Seine tribunal in 1865, and in 1877 accepted a post in the Ministry of Justice. He was editor of *Le Parlement* and in 1878 succeeded Thiers at the Academy of Moral and Political Sciences, where he became permanent secretary in 1896. Among his publications are 'Recherches sur la Mise en Liberté sans Caution' (1863); 'Histoire des Etats Généraux' (1872); 'La Réforme Judiciaire' (1881); 'Décentralisation et ses Différents Aspects' (1897); 'L'Institut de France' (1907), etc.

PICPUS, Society or Congregation of, a religious association founded in Paris, 1805, by Pierre Coudrin, priest. The associates were to devote themselves, as a protest against the prevailing unbelief, to the perpetual adoration of the Blessed Sacrament; they were also to prepare candidates for the priesthood and for service in the foreign missions. The mother house was the conventual building of the original congregation of Picpus, a Franciscan fraternity. They had charge of seminaries in various parts of France. In 1825 they sent six of their priests to the mission in the isles of the Pacific, and those islands have ever since been the field of their missionary labors. They have two houses in the United States, at Olema, Cal., and Fairhaven, Mass.

PICQUART, Georges, zhŏrzh pē-kär, French soldier, prominent in "the Dreyfus case"; b. Strassburg, 6 Sept. 1854; d. 19 Jan. 1914. He entered Saint Cyr in 1872, and, after two years there, spent two more in the Ecole d'Etat-major, from which he was graduated in 1876 with the second rank in his class. From the General Staff School he entered the infantry; became captain in 1880 and major in 1888 upon his return to France from three years in Tonkin; in 1890–93 was professor at the Superior Military School; was promoted lieutenant-colonel in 1896; and in the year before became head of the Department of Information. In May 1896 he obtained possession of a telegram card, the famous *petit bleu,* addressed to Esterhazy, which prompted him to inquire into that officer's record and way of life. The result was that he found Esterhazy's writing was clearly that of the famous bordereau; it was identified as such by Bertillon of the Paris police and by Du Paty de Clam. His investigations were soon interfered with by his superiors; he was disgraced and sent to Tunis 16 Nov. 1896, the Department of Intelligence being entrusted to Colonel Henry, who concealed the truth so far as he could and later committed suicide, when his dishonesty had been disclosed. Picquart apparently had been sent to Tunis in the hope that he would be killed in battle. This not happening, in May 1897 he was accused of forging the *petit bleu,* which had roused suspicion against Esterhazy. His bold action in repelling this charge hastened the revision of the case. He was retired from the army February 1898, having been arrested by the military authorities a month before. On 14 July he was again imprisoned in a civil prison; and 20 September was charged with forgery and with tampering with the Esterhazy telegram card. After a long imprisoment in the Cherche-Midi he was released and was the most prominent witness

in the Rennes trial of 1899. At the retrial of the case 19 June–12 July 1906, he was acquitted of all charges, subsequently promoted brigadier-general and in October 1906 became Minister of War in the cabinet of M. Clemenceau, where he remained until 1909. See DREYFUS.

PICQUET. See PIQUET.

PICRATE. See PICRIC ACID.

PICRIC ACID, or **TRINITROPHENOL,** $C_6H_2OH(NO_2)_3(1, 2, 4, 6)$, was discovered by Woulfe in 1771. It is formed by the action of nitric acid on indigo, wood, silk, leather, aloes, resins, and many derivatives of benzene. On a commercial scale picric acid is manufactured from phenol by first treating it with sulphuric acid. The sulphonic acid produced in this way is diluted with water to 30° Bé. and heated with steam. Phenol para-sulphonic acid is produced under these conditions which yields picric acid when it is nitrated with about 3.5 times its weight of nitric acid of 40° Bé. The crystals obtained on cooling the reaction mixture are washed, and further purified by recrystallization from hot water. A product of high purity may be obtained by converting the compound into the sodium salt and reprecipitating it with excess of hydrochloric acid. Very pure picric acid has been obtained directly by the nitration and subsequent hydrolysis of chlorobenzene, the reagents used being crude sodium nitrate and commercial sulphuric acid. Picric acid may also be prepared by the oxidation of trinitrobenzene, or, the nitration of diazobenzene sulphonic acid.

Picric acid is a yellow, crystalline substance with a melting point of 122.5° C. With many metals it forms salts which are highly explosive. It is not very soluble in cold water, but will readily dissolve in alcohol, ether, benzene and other solvents. Solutions of picric acid, especially those of its alkaline salts, show an intense yellow coloration. Picric acid is a violent explosive but does not readily explode on mere heating. Under ordinary conditions the application of heat may either cause rapid combustion, or sublimation with the liberation of yellow, irritating vapors. The acid will explode with violence when dropped upon a red-hot plate. Disastrous explosions in picric acid factories are on record. These have in all probability been caused by metallic picrates present as impurities in the acid, or, by the combustion of picric acid dust produced during the grinding of the dry compound. The acid can be handled with perfect safety, and can even be transported as an ordinary chemical when it contains 20 per cent of water.

Picric acid is extensively employed as a powerful explosive. Melinite, Lyddite, Shimosite, Emmensite, etc., are mixtures of the acid with small quantities of gun-cotton. On account of their great sensitiveness metallic picrates are sometimes mixed with chlorates or nitrates and employed as detonating charges for shells. Picric acid has been used as a dye for silk and wool. In an acid bath it imparts an intense yellow color to these fibres. Although the acid is not used as a dye at the present time, it is sometimes mixed with other dyes for the production of shades of scarlet, green or yellow. In the laboratory picric acid is a valuable reagent since it forms well crystallized and difficultly soluble compounds with a number of organic bases. Picric acid has also been used by brewers for the purpose of imparting bitterness to beer. In large doses the acid behaves as a poison, causing purging, vomiting and collapse, although small quantities have been employed with success in the treatment of eczema, erysipelas and in diseases of the skin and hair. Solutions of varying strengths have also been highly recommended in the treatment of burns.

V. S. BABASINIAN,
Professor of Lehigh University.

PICROLITE, pĭk'rô-līt, a type of serpentine (q.v.) with columnar fibrous structure, originally found at Taberg, Sweden. While its composition and structure classifies it as a type of asbestos, it is of no commercial importance. In color it is dark green, gray, or brown.

PICROMERITE, a monoclinic mineral occurring as crystals and crystalline incrustations, a compound of hydrous sulphate of magnesium and potassium. It is found in the crater of Vesuvius and also in the salt mines of Stassfurt.

PICROTOXIN, a poison, $C_{30}H_{34}O_{13}$ (or possibly $C_{12}H_{14}O_5$), extract from the Indian berry, the fruit of the East Indian *Anamirta cocculus* or *paniculata,* by treating with hot alcohol the powdered seed. The alcohol is distilled, the residue boiled with water to which the acetate of lead has been added and the solution then evaporated. The crystals, white or transparent prisms or rays grouped in star-like forms, are very bitter to the taste, are odorless, inalterable in the air, insoluble in the essential oils, but soluble in cold water (150 times its bulk), boiling water (25 volumes), alcohol (3 volumes), or ether (2½ volumes), and are one of the most violent convulsive poisons known, closely resembling strychnine in their action. The poison brings death by asphyxiation after severe convulsion and is bulbomedullary and not cerebral in its action. Morphine and chloral hydrate are the antidotes, but neither seems to have antidotic force if the original dose is much above the mortal minimum. In therapeutics picrotoxin is practically unused, though it is claimed to be valuable in epilepsy, chorea, chronic constipation, etc.

PICTET, Raoul, Swiss physicist: b. Geneva, June 1842. He was professor in Geneva for a time, but removed to Berlin. In 1877 he liquefied oxygen, nitrogen and hydrogen; published a memoir on that subject in 1878; and also wrote 'Synthèse de la Chaleur' (1879), 'Nouvelles Machines frigorifiques' (1885), 'Le Matérialisme et le Spiritualisme par la Physique expérimentale' (1896), 'L'Acétylène' (1896), and other important monographs, on low temperatures and liquefaction of gases. Deceased.

PICTET'S LIQUID. A liquid used for producing low temperatures. It is stated to be a mixture of liquid carbon dioxide and sulphur dioxide.

PICTON, pĭk'tŏn, SIR **Thomas,** English military officer: b. Poyston, Pembrokeshire, Wales, August 1758; d. Waterloo, Belgium, 18 June 1815. He entered the army at 13, served at Gibraltar, and in 1794 went to the West Indies, where he distinguished himself at Saint Lucia, Saint Vincent, Martinique and Trinidad, and in 1797 was appointed governor-general of the last-named island. In 1801 he became

its civil governor and was promoted brigadier-general. He served in the Peninsular War under Wellington, received rank as lieutenant-general in 1813, was engaged with Ney at Quatre Bras in 1815 and was killed while leading a charge at Waterloo.

PICTON, Canada, county town of Prince Edward County, Ontario, about 36 miles SW. of Kingston; center of large canning industry; annual boat regatta on Picton Bay attracts thousands. Pop., 3,539.

PICTONES, pĭk'tŏn-ēz, or **PICTAVI** (*Pictŏnes, Pictăvi*), the ancient inhabitants of a region in Aquitanian Gaul, the French province of Poitou, which is now for the most part comprised in the Department of Vienne; the chief town of the Pictonēs was Pictava, modern Poitiers, before the Roman conquest of Aquitania its name was, as rendered by the Latins, Limonum.

PICTOR. See Equuleus.

PICTORIAL COMPOSITION. See Art Drawing.

PICTORIAL REPRESENTATION. See Art Drawing.

PICTOU, Canada, a port of entry and capital of a county of the same name, Nova Scotia, 100 miles northeast of Halifax, on a branch of the Canadian National Railways. The town, which occupies the site of an old Indian village, was settled in 1763, but received its first permanent residents from the ship *Hector,* the first of several emigrant vessels taking settlers from Scotland, which arrived in 1773. Pictou Academy, founded in 1818, by Dr. Thomas MacCulloch, became widely known for its many distinguished graduates. The harbor is safe and commodious. An active trade is carried on in coal, lumber, and fish. Pop. 3,172.

PICTS. See Scotland.

PICTURED ROCKS, in Michigan, sandstone cliffs about 300 feet in height, extending along the coast of Alger County, on the south shore of Lake Superior, about 43 miles east of Marquette. They are varied in color and form, quaint designs have been carved upon them by the elements and a number of waterfalls still continue the work of change. The cliffs are about five miles long. Longfellow, in his Indian tale of Hiawatha, locates the wigwam of Nokomis at Munising Harbor, among the Pictured Rocks.

PICTURES OF TRAVEL (Reisebilder), the most famous of the prose works of Heinrich Heine. It was published in four parts, 1826–31, and the appearance of the first book of these sketches marked an epoch in the development of German literature. It was read with avidity by the public and so strong was its influence that it gave the first serious check to a prevailing tendency in the world of letters — the romantic tendency. The power of the Romantic School was broken by the vivid realism of Heine's 'Hartz Journey.' The keen observation of the great lyrist and satirist, his brilliant searching criticisms of men and institutions, his stinging sarcasms poured out on existing conditions, were entirely opposed to the spirit of Romanticism, and its author attained at once to almost as widespread a recognition as he was ever to reach among his countrymen. The brilliancy and bitterness, the sweetness and the mockery, of his strange nature, are all brought into play in this, his first prose work of significance.

PICUDA, a fish. See Barracuda.

PICUL (also pecul and pecal), a Chinese weight equivalent to 133⅓ pounds avoirdupois; the same as the tan. It is divisible into 100 catties; or into 1,600 taels (of 1⅓ ounces each).

PICUS, pī'kŭs (Lat., the woodpecker), in the most ancient mythology of the Sabines, Latins and Etrurians, the sacred bird of the god of the upper atmosphere, of the land and agriculture, sender of rain, giver of fertility. This god was Mars, Mavors or Marspiter (*Mars pater,* father Mars), who afterward was supplanted by the more than half-Grecian god Jupiter (father Jove), while Mars or Mavors was assimilated to the Grecian god of war, Ares. The Latin god Mavors gave oracles by means of the noises made by the woodpecker tapping on the trees. In the confusion of the diverse mythologies, Sabine, Roman, Latin, Etrurian, the woodpecker, Picus became a form of the god himself, or son of the god and a famous hero, king of Latium, and father of Faunus.

PIDAL, pē-däl, **Ramón Menédez,** Spanish philologist, critic and educationalist: b. Coruña, 13 March 1869. Educated at the universities of Madrid and Toulouse he became professor of Roman philology at the former university (1899). His markedly critical mind, his mastery of the French tongue and his extensive writings soon won for him an international reputation and he was invited to lecture in the universities of various foreign countries, principally those of South America. He has also given courses of lectures in Johns Hopkins University (1909), the Turnbull lectures; and in most of the universities of Spain. He also delivered the Hispanic Society lectures at Columbia University in 1909. Thus he came to be recognized as one of the foremost and most progressive educationalists in Spain. Shortly after the formation of the Junta para Ampliación de Estudios (a board created in 1907 for the extension and improvement of university studies throughout Spain), he became a member of the organization and director of its summer session; and in 1913 Counselor of Public Instruction in Spain. His services in these and other educational and literary capacities gained for him membership in practically all the noted literary organizations of his native country, among them being the Royal Academy of History, Madrid, and the Academia Real de la Lengua; and also of the Hispanic Society of America. The Academia Real de la Lengua crowned his 'Gramática y vocabulareo de poema del Cid,' and the same honor was extended to his 'Leyenda de los infantes de Lara' by the Royal Academy of History. In the field of Spanish philology he occupies a distinguished place which may be said to make him a noted specialist in his line of work. Among his published works are 'L'Epopéc castillane à travers la littérature espagnole' (his Turnbull lectures, 1910); 'El Romancero español' (Hispanic Society Lectures at Columbia); 'Gramatica Historica Española'; 'Leyenda de abad Don Juan de Montemayor'; 'Primera crónica general'; 'Cantor de mio Cid' (3 vols., 1908–

11); 'Cancionero de romances impreso en Amberes sin Ano' (1914).

PIDAVRO. See EPIDAURUS.

PIDDIG, pē-dēg', Philippines, pueblo, province of Ilocos Norte, Luzón; on the Guisi River, near its junction with the Pagsán; nine miles east of Laoag, the provincial capital. It is connected with Laoag and other towns by wagon road. Pop. 10,850.

PIDDOCK, the British name for certain edible species of mollusks of the genus *Pholas.* See DATE-SHELL.

PIDGIN, pĭj'in, **Charles Felton,** American novelist: b. Roxbury, Mass., 1 Nov. 1844; d. 3 June 1923. He was in mercantile employment in Boston 1863–73, becoming in the latter year chief clerk of the Massachusetts bureau of statistics of labor. He invented several machines for the mechanical tabulation of statistics, among them the electric adding and multiplying machine, addition register and typewriter tabulator. He published 'Practical Statistics' (1888); 'Quincy Adams Sawyer' and 'Mason's Corner Folks' (1900); 'Blennerhassett' (1901); 'Stephen Holton' (1902); 'The Climax' (1902); 'Little Burr' (1905); 'Theodosia' (1907); 'Labor, or the Money God' (1908); 'Further Adventures of Quincy Adams Sawyer' (1909); 'Chronicles of Quincy Adams Sawyer, Detective' and 'The House of Shame' (1912); 'The Courtin'' (a comic opera, 1913). He also composed several musical works, among them 'Cambyses,' a grand opera, and 'Peck's Bad Boy,' a musical comedy. He was also the author of some 35 songs.

PIDGIN, or **PIGEON, ENGLISH,** a form of "business English"; a conglomeration of English and Portuguese words wrapped in a Chinese idiom, used by English and American residents in China in their intercourse with the natives. It accommodates the Chinese inability to sound the *r,* which is always *l,* and it adds the long *ē* or *ee* (double *e*) after consonants that trouble the Chinese tongue. Thus price becomes "plice," and wash is "washee." Some pidgin English has drifted into American use as "chow-chow," meaning food, or as a verb, to eat; and "savey," which is accepted slang for know.

PIED (pīd) **PIPER OF HAMELIN, The,** according to a legend a magician who promised to rid the town of Hamlin from rats for a stipulated sum of money. He performed his task by playing on his pipe as he walked to the river and the rats, following the music, were consequently drowned. On the citizens then refusing to pay the money the piper took up his pipe once more and led the way out of the town followed by 130 children. On arriving at a hill known as the Koppenberg they all entered the hill and vanished from sight. In the Hamelin Rathaus the event is recorded and it was long supposed to be historical. Browning's poem, 'The Pied Piper of Hamelin' (1842), is based on this tale.

PIEDMONT, pēd'mŏnt (Italian, *Piemonte,* "Country at the Foot of the Mountains"), Italy, a department including the provinces of Alessandria, Aosta, Cuneo, Novara, Torino and Vercelli. Beyond the Alps lie France and Switzerland; the Apennines separate it from the Italian Riviera, and its streams flow into the Po. It was a part of France from 1797 to 1814, and was at one time the chief part of the Kingdom of Sardinia (q.v.). Silk culture is a flourishing industry. Farming is carried on, mainly on the shares, the tenant dividing with the owner of the land. Area, 11,331 square miles; pop. 3,383,646. See ITALY.

PIEDMONT, Battle of. After the battle of New Market (q.v.), 15 May 1864, General Sigel was relieved, and 21 May General Hunter was assigned to the command of the Union forces in the Shenandoah Valley. The command in the field consisted of Gen. J. C. Sullivan's division of infantry, two brigades, under Colonels Moor and Thoburn; Gen. J. Stahel's division of cavalry, two brigades, under Colonels Tibbits and Wynkoop, and five batteries of artillery. With this force of 8,500 men and 21 guns, Hunter broke camp on Cedar Creek on the 26th to move on Staunton and Lynchburg, marched to Woodstock, and thence to Harrisonburg, where, 2 June, he learned that General Imboden was at Mount Crawford, eight miles distant, barring the direct road to Staunton. He avoided Imboden by passing his right by way of Port Republic. From his camp one mile south of Port Republic he advanced early on the morning of the 5th on the Staunton road, met the Confederate cavalry at 6 A.M., and drove them after a sharp skirmish, with a loss of 75 men killed, wounded and missing. At Piedmont, seven miles southwest of Port Republic, Hunter found Gen. W. E. Jones with a Confederate force of 6,000 men and 12 guns, strongly posted, his left resting on Middle River, a tributary of the Shenandoah. Line was formed; Moor's brigade on the right; Thoburn's on the left; Wynkoop's cavalry massed in rear of Moor. Hunter's artillery opened at 9 A.M., and after a fire of less than two hours Moor attacked the Confederate left and drove the first line back on the second, which was on a curving ridge of heavily wooded hills, and on reaching which Moor was checked and fell back with some loss, the Confederates following, but soon checked in turn by Moor, aided by the cross-fire of three batteries. Meanwhile Thoburn had crossed a ravine to gain the Confederate right flank. Securing an advantageous position, he made a charge on the woods and heights; there was a fierce struggle, in which bayonets and clubbed muskets were used on both sides; Moor and Wynkoop co-operated in the attack; and the Confederates abandoned their position in great disorder, leaving General Jones dead on the field, with more than 1,000 prisoners, including 60 officers. In killed and wounded the Confederate loss was about 600. The next day Hunter captured 400 sick and wounded. Three guns, several battle-flags, and a large number of small arms were captured. Hunter's loss was 420 killed and wounded. General Vaughn, who succeeded Jones in command, fled with not over 3,000 effective men to Waynesboro, and abandoned Staunton. Hunter marched to Staunton on the 6th, where he was joined on the 8th by Generals Crook and Averell, who had marched from West Virginia, with 10,000 men, raising his force to 18,000 men, with 30 guns. He destroyed much public property in Staunton, broke the railroad several miles east and west of it, and on the morning of the 10th

marched for Lynchburg. Consult 'Official Records' (Vol. XXXVIII); Pond, 'The Shenandoah Valley in 1864'; The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

PIEDMONT ALLUVIAL PLAINS. See ALLUVIAL CONES AND FANS.

PIEDMONT PLAIN, the name given to that part of the Atlantic coastal plain, in the United States, which lies between the Appalachian highland and the coastal plain proper. This plain is well defined in the Southern States, but not so distinct in New England. It is nearest to the ocean in New York; in North Carolina it is about 300 miles wide. It is crossed by deep river valleys, and is seamed with rugged gorges, and water beds. The rock is harder and older than in the coastal plain proper, belonging chiefly to the Pre-Cambrian. The "fall line," or escarpment over which the Atlantic rivers fall and form cascades and rapids, marks the change from the hard rocks of the Piedmont to the softer rock formations of the Coastal Plain.

PIEDMONTITE, pēd'mŏnt-īt, a manganese-bearing type of epidote occurring at St. Marcel in the Aosta valley of Piedmont, France, whence its name; it is also found in Brittany, England, Japan, and Sweden.

PIEDS PUIDREAUX, pē-a pwē-drō. See PIEPOWDER COURT.

PIEGAN (pē'gan) **INDIANS,** an American tribe of the Algonquin family. Some 2,000 of them reside on the Blackfoot Reservation in northern Montana. They are members of the Siksika confederacy, being associated with the Siksikas, Bloods and other tribes. They are a very peaceable people and crime is almost unknown among them.

PIEHL, pēl, **Karl,** Swedish Egyptologist: b. Stockholm, 30 March 1853; d. 1904. He was educated at Upsala, where he became docent of Egyptian languages in 1888, and in 1893 professor upon a special grant by the Riksdag. He published 'Inscriptions hiéroglyphiques' (1884–99), 'Petites Etudes égyptologiques' (1881), 'Dictionnaire du Papyrus Harris Nr. 1' (1882), and many contributions to archæological periodicals. In 1896 he became editor of *Le Sphinx,* an Egyptological journal.

PIENG-AN. See PING-YANG.

PIENO (Ital., meaning full), a term often used in music as equivalent to *tutti, grande* or *grossi,* to signify employment of all the instruments of an orchestra; sometimes it is used with *coro,* as *pieno coro,* full chorus.

PIEPER, Franz August Otto, American Lutheran theologian: b. Germany, 27 June 1852; d. 3 June 1931. He came to the United States in 1870; was graduated from Northwestern University (Wis.) in 1872; from Concordia Seminary in 1875; and held a pastorate at Manitowoc, Wis., 1875–78. He was professor of theology at Concordia Lutheran Theological Seminary, 1878–87; and president of that institution from 1887 until his death. He published numerous books on religious subjects.

PIEPOWDER (pī'pow-dėr) **COURT,** or **PIERPOUDRE COURT,** a court formerly set up at fairs and markets in England for the summary administration of justice in cases arising there. It is also called the Court of Dusty Foot, which has the same meaning as piepowder (a corruption of the French *pied poudreux*), and probably got its name from the fact of its being chiefly resorted to by peddlers and wayfaring persons, to whom the name of *pieds puidreaux* was given in Old French.

PIER, Arthur Stanwood, American novelist: b. Pittsburgh, 21 April 1874. He was graduated from Harvard in 1895, and was assistant editor of the *Youth's Companion* from 1896 to 1925. His works include 'The Pedagogues' (1899); 'The Triumph' (1903); 'The Ancient Grudge' (1905); 'The New Boy' (1908); 'The Crashaw Brothers' (1910); 'The Jester of Saint Timothy's' (1911); 'The Story of Harvard' (1913); 'The Women We Marry' (1914); 'Jerry' (1917); 'The Son Decides' (1918); 'The Hilltop Troop' (1919); 'David Ives' (1922); 'Confident Morning' (1925); 'Friends and Rivals' (1925); 'The Coach' (1928); 'The Captain' (1929); 'The Rigor of the Game' (1929).

PIER, *in engineering,* a structure built out from the land into water to form a landing for passengers or freight from vessels lying in deep water alongside the pier or wharf; a mole or jetty. Many large and commodious piers have been built at watering places to receive incoming visitors and these are often fitted up with booths, bandrooms, dancing pavilions, etc. They are variously constructed. Some are founded on piles, with cross timbers, braces and sheathing; floor timbers affording a road for the traffic. The wooden structure is sometimes filled up with stone, like a dike; at other times it is of the nature of trestle work. The name is extended to any plain single mass of masonry supporting a large structure, as a bridge pier, foundation pier. A section of a brick or stone wall between windows is also termed a pier, whence comes the term pier-glass, for a long mirror suited to such a position. See FOUNDATIONS; HARBORS; MOLE; WHARVES.

PIERCE, pērs, **Franklin,** 14th President of the United States (1853–57): b. Hillsboro, N. H., 23 Nov. 1804; d. Concord, N. H., 8 Oct. 1869. His father, Benjamin Pierce (1757–1839), served in the Revolutionary War, was member of the State legislature 1789–1801, and from 1803 to 1809. He was a Democrat in politics, an active public-spirited man, and governor of New Hampshire from 1827 to 1829. His son, therefore, was brought up in an atmosphere of public service. Franklin Pierce was educated at various academies, Hancock, Francestown and Phillips Exeter, entered Bowdoin College, Maine, 1820, and had as classmates Longfellow and Hawthorne. He graduated third in his class in 1824 and studied law for the next three years, first with Levi Woodbury at Portsmouth, then at the law school of Judge Howe at Northampton, Mass., and finally with Judge Edmund Parker at Amherst, N. H. He was admitted to the bar in 1827 and entered politics almost immediately as a Democrat. In 1829 he was elected as a representative to the State legislature, and in 1832 was made speaker. In 1833 he entered Congress, became a close friend of Jackson and sustained him in important contests. His career in the House of Representatives during the next four years was uneventful, because most of his work was done in the committee-room. He rarely made a speech,

and then not on the most important questions. He spoke 27 Feb. 1834, against the bill on the subject of Revolutionary claims, on the ground of economy and justice; and on 30 June 1836 against the bill making appropriations for the United States Military Academy, on the ground that it was legislation conferring "exclusive and gratuitous privileges." He approved of Jackson's veto of the Maysville road bill, and in general was a believer in a strict construction of the Constitution. In December 1835 he spoke and voted against the policy of receiving petitions for the abolition of slavery in the District of Columbia. In 1837 Pierce was elected to the Senate, but was overshadowed by such men as Clay, Calhoun, Webster and Benton, Pierce being the youngest of all the senators. He seldom spoke and avoided, as in the House, the big questions of the day. He resigned in 1842 to accept the office of district attorney of New Hampshire.

When the Mexican War broke out in 1846, he enlisted as a private, enrolled in a company of volunteers organized at Concord, and soon received from the President a commission as colonel of the Ninth regiment. On 3 March 1847, he was commissioned as brigadier-general in the volunteer army, though practically without military experience. He was with General Scott in the march on the City of Mexico, but did not play a conspicuous part in the military operations. After his return home he engaged in the practice of law. The Democratic National Convention met at Baltimore 1 June 1852, with Lewis Cass, James Buchanan and Stephen A. Douglas as the leading candidates. On the 35th ballot the Virginia delegation voted for Pierce, and on the 49th he received 282 votes to 6 for all other candidates. This "dark horse" Presidential candidate was a real surprise to most people. The reasons for passing by the three leading candidates mentioned above were varied. Since each had a large following there was bitter personal rivalry, and this made the success of any one a matter of considerable doubt. The chief concern of the leaders was to placate the South and avoid the growth of a purely sectional party. Accordingly, the convention adopted a resolution pledging the party to enforce the compromise of 1850. Pierce was favorable to the institution of slavery, believing that it was guaranteed by the Constitution, and was thus considered a "safe man" by the South. In the election which followed in November, he received 1,601,474 popular votes to 1,386,580 for Gen. Winfield Scott, the Whig candidate, and at the meeting of the electoral college 254 votes to 42 for Scott. All of the States voted for Pierce excepting Vermont, Massachusetts, Tennessee and Kentucky. He was inaugurated 4 March 1853, and on March 7 announced his Cabinet, namely, William L. Marcy of New York, Secretary of State; James Guthrie of Kentucky, Secretary of the Treasury; Jefferson Davis of Mississippi, Secretary of War; Robert McClelland of Michigan, Secretary of the Interior; James C. Dobbin of North Carolina, Secretary of the Navy; James Campbell of Pennsylvania, Postmaster-General, and Caleb Cushing of Massachusetts, Attorney-General.

The election of Pierce may be considered primarily as a verdict in favor of carrying out the terms of the compromise of 1850 and the policy of expansion. In his first inaugural address Pierce said: "The policy of my administration will not be controlled by any timid forebodings of evil from expansion." He also declared that "our position on the globe renders the acquisition of certain possessions not within our jurisdiction eminently important for our protection." This doubtless referred to Cuba, much desired by the southern expansionists for additional slave territory. Pierce appointed Pierre Soulé of Louisiana as Minister to Spain, a man who had previously declared in open senate his desire to annex Cuba to the United States by some other method than by purchase. In August 1854, Secretary of State Marcy suggested that Soulé, James Buchanan, and John Y. Mason, ministers respectively to Spain, England and France, have "a full and free interchange of views" in regard to the acquisition of Cuba. The result was a meeting at Ostend, where on 9 Oct. 1854 they drew up the famous Ostend Manifesto, in which Spain was urged tc sell Cuba to the United States, and in case of refusal the question should be considered whether the interests of the United States were endangered by Cuba remaining in the possession of Spain. If answered in the affirmative, then "by every law, human and divine, we shall be justified in wresting it from Spain if we possess the power." The exact relation of Pierce to this document is not fully known. It was disavowed by Secretary of State Marcy in the name of the President, but Pierce was held as more or less responsible for the incident by his enemies.

Moreover it was during the administration of Pierce that William Walker carried out his notorious filibustering expeditions in Central America, for the purpose of setting up a government under American rule favorable to slavery. In June 1855 he entered Nicaragua with a small force, captured Granada on 13 October, procured his election as President in July 1856, and proclaimed Nicaragua a slave State. His dominion was recognized by the American minister resident, and Pierce received Walker's envoy, though he had previously issued proclamations warning the people against armed expeditions to countries with whom the United States was at peace. Ministers from other Central American republics protested against this violation of neutrality, but to no purpose.

Pierce supported several other policies of importance. He wished to expand American commerce as rapidly as possible, first by federal subsidies to shipping and second by opening up new areas for trade. Commodore Perry was sent to Japan to induce this nation to open her ports to American trade and was successful in his mission. Pierce also supported the plan of linking California more closely with the rest of the country by means of a transcontinental railroad. The best route lay through territory, a portion of which was in the possession of Mexico. Accordingly James Gadsen was sent to Mexico to purchase a strip of territory on the southern border of New Mexico. He secured a tract of some 50,000 square miles for $10,000,000, which was known as the Gadsen purchase. The railroad was planned largely to benefit the economic development of the lower

South, and Congress voted the funds for the survey of routes. Pierce advocated the building of the railroad in his first annual message, and handed over the work of seeing to the survey to Jefferson Davis.

Another policy was the opening up of the Northwest to settlement. The platform of the Democratic party declared that the party "will resist all attempts at renewing, in Congress or out of it, the agitation of the slavery question, under whatever shape or color the attempt may be made." Pierce also, in his inaugural address, advised against the reopening of the slavery question. Nevertheless the conflict over the extension of slavery into the territories was the great event of his administration. The occasion was the plan of Senator Douglas to open up the great Northwest to settlement, remove the Indians to reservations or to the Southwest, connect Chicago with the Pacific Northwest by a railroad, open the territory to slavery and thereby become the next President of the United States. The supremacy of the Northwest was at stake and this was a plan to checkmate the South for a Southern Pacific railroad. Douglas won the support of the Middle West, western Missouri, and powerful interests in the South. This last because of a promise that the Kansas-Nebraska bill should contain a clause giving settlers the right to determine for themselves whether they would have slaves — the doctrine of popular sovereignty. Thus the Missouri Compromise of 1820 prohibiting slavery in the Louisiana territory north of 36° 30′, except Missouri, would be repealed. Pierce gave his support to this plan and signed the bill. Thus he aided the South in its desire for the extension of slavery into the territories, although the most of the Northwest would in the end naturally become free territory. This action of Pierce wrecked his administration. He immediately organized Kansas and Nebraska as territories, and supported the pro-slavery party in Kansas during the remainder of his term of office, in an effort to prevent the admission of Kansas as a free State. Thus he helped make the Democratic party of the North subservient to that of the South, and supported the slave power in its extreme demands for more slave territory. He believed that this would satisfy the South and thus disunion and civil war would be avoided. He was under the influence of Jefferson Davis, his Secretary of War, and this accounts, in part, for his attitude on several important public questions. After his retirement from the presidency he traveled in Europe for three years, returning home early in 1860. He was opposed to the methods of the Abolitionists, but supported the North when war broke out.

Pierce did not measure up to the standard of most of the Presidents. He was not a commanding figure in any field. He was honest in his intentions as a conciliator of the two sections, in his belief that the Constitution guaranteed slavery as an institution, and that the way to avoid civil war and disunion was to support the South in this view. His strong leaning toward the South, however, really had the effect of promoting sectional strife and finally in leading to civil war. He was an amiable, honest, generous, modest, educated gentleman, but lacked intellectual acumen and that idealism necessary for great leadership. His chief stock in trade was attention to legislative details, fidelity to party, winning manners, and a neutral compromising character which was a negative rather than a positive and constructive force. His last years were passed at his home at Concord, N. H., beloved by his personal friends but almost forgotten by his countrymen.

Bibliography.— There is no good life of Pierce. The early biographies were published for campaign purposes and do not cover his term of office. Consult life by Bartlett, D. W. (Auburn N. Y., 1852), and by Hawthorne, Nathaniel (Boston 1852), both eulogistic accounts; Ireland, J. R., 'History of Life and Administration and Times of Franklin Pierce' (Chicago 1888), in Vol. XIV of his Republic. See also Richardson, J. D., 'Messages and Papers of the Presidents' (Washington 1897); Leech, W. L., 'Calendar of the Papers of Franklin Pierce' (Washington 1917). Some of his correspondence is printed in *American Historical Review,* Vol. X, 110–127, 350–370. The best accounts of his administration are in Schouler, James, 'History of the United States' (New York 1894), Vol. V; Rhodes, James Ford, 'History of the United States from the Compromise of 1850' (Vols. I–II, New York 1900); von Holst, Hermann, 'Constitutional History of the United States' (Vols. IV and V, Chicago 1899). See also 'Pierce Genealogy.'

MARCUS W. JERNEGAN,
Former Professor of History, U. of Chicago.

PIERCE, George Foster, American Methodist bishop, son of Lovick Pierce (q.v.): b. Greene County, Ga., 3 Feb. 1811; d. near Sparta, Ga., 3 Sept. 1884. He was graduated from Franklin College, Athens, Ga., in 1829, and entered the ministry in 1831. He attained great popularity as a preacher, was president of the Georgia Female Seminary, Macon, Ga., in 1839–42, of Emory College, Oxford, Ga., in 1849–54 and was elected bishop in the latter year. He was a member of the convention which met at Louisville, Ky., in 1846, and organized the Methodist Episcopal Church, South, and was prominently connected with it until his death. Consult 'Life' by George G. Smith (1888).

PIERCE, Lovick, American Methodist clergyman: b. Halifax County, N. C., 17 March 1785; d. Sparta, Ga., 9 Nov. 1879. He entered the Georgia Conference in 1805, was chaplain in the army in the War of 1812, and afterward studied medicine, which he practised until 1821, when he re-entered the ministry. He was prominently connected with the organization of the Methodist Episcopal Church, South, in 1846, and was famous for pulpit eloquence.

PIERIANS, pī-ē′rĭ-ạnz, or **PIERIDES,** pī-ĕr′ĭ-dēz, a name given the Muses, from their birthplace, Pieria in Thessaly.

PIERIDÆ, a large family of butterflies, of medium or large size, and chiefly white and yellow in their coloration, and represented in all parts of the world. They are distinguished from their nearest relatives, the *Papilionidæ* (q.v.), by the fact that all six legs are fully developed in both sexes; and from the *Hesperidæ* and *Lycænidæ,* by the greater specialization of the neuration of the wings.

The common «cabbage butterfly» is a typical representative. A well-known American genus is the *Euchloë*, the «Orange-tips.»

PIERNÉ, Gabriel, French composer: b. Metz, Germany, 1863; d. Brittany, 17 July 1937. He was graduated from the conservatory at Paris and in 1822 won the Prix de Rome; in 1890 he was appointed organist at Saint Clothilde and thereafter devoted much time to composition. His operas were very successful, particularly 'Izéil' (1894): He brought out the oratories of 'Les Enfants de Bethlehem' (1907), and 'Saint Francois d'Assisi' (1913).

PIERO DI COSIMO, pē-ā-rō dē kō-sē-mō, Italian painter: b. Florence, about 1462; d. there, 1521. He was a pupil of Casimo Roselli and at times was influenced by Signorelli, Filippino and Leonardo da Vinci. He devoted himself to landscape backgrounds, which were always ably executed, if somewhat fantastic in character. This feature is especially notable in his 'Death of Procris' (National Gallery, London). His pictures are somewhat rare, though the galleries of Florence, Rome, Paris and London possess several specimens.

PIERO DELLA FRANCESCA. See FRANCESCA, PIERO DELLA.

PIEROLA, pē-ā-rō'lä, **Nicholas de,** Peruvian politician: b. Camana, Peru, 5 Jan. 1839; d. 1913. He was educated in the college of Santo Toribio in Lima, admitted to the bar in 1860 and was connected with various journalistic enterprises. In 1869–72 he was Minister of Finance under President Balta. Impeached under the administration of Pardo, he came to the United States, though acquitted, and interested himself in revolutionary schemes. At the outbreak of the war between Chile and Peru his services were accepted by President Pardo and he returned to Peru in 1879. Upon the flight of Pardo he headed a revolt against the government, but was defeated. In 1885 he was banished for attempting to seize the presidency, but in 1894 headed a revolt which succeeded in overthrowing President Cáceres. Pierola was thereupon elected President and served until the end of his term in 1899.

PIERPONT, pēr'pŏnt, **Francis Harrison,** American politician: b. Monongalia County, Va. (now West Virginia), 1815; d. Pittsburgh, Pa., 24 March 1899. He was graduated from Allegheny College, Meadville, Pa., in 1839, was admitted to the bar and established a law practice in Fairmount, Va., where he soon became widely known. He was a staunch Whig and Abolitionist and at the outbreak of the Civil War remained loyal to the Union, organized the convention which decided that the western part of Virginia should remain in the Union and was elected governor of the «Restored Government of Virginia.» He was recognized by President Lincoln, authorized to raise troops for home protection and after serving two years of the unexpired term was re-elected for a term of four years. After the organization of West Virginia as a State and her admission into the Union Governor Pierpont removed his capital to Alexandria and after the evacuation of Richmond transferred the government to that city, where he continued as governor of the loyal section of the State until 1868. In 1868–70 he served in the legislature and afterward lived in retirement until appointed internal revenue collector by President Garfield.

PIERPONT, James, American mathematician: b. about 1863. In 1886 he was graduated at the Worcester Polytechnic Institute and in 1894 he received the degree of Ph.D. at the University of Vienna. In 1899 he received the honorary degree of M.A. from Yale University and in 1909 that of LL.D. from Clark University. In 1894–95 Pierpont was lecturer in mathematics, in 1895–96 instructor, in 1896–98 assistant professor; thereafter until he retired, full professor at Yale. His published works are 'Lectures on the Theory of Functions of Real Variables' (1905); 'The History of Mathematics in the Nineteenth Century' (1905); 'Functions of a Complex Variable' (1914). D. New Haven, Conn., 9 Dec. 1938.

PIERPONT, John, American Unitarian clergyman and poet: b. Litchfield, Conn., 6 April 1785; d. Medford, Mass., 27 Aug. 1866. He was graduated from Yale in 1804, studied law at Litchfield and after admission to the bar of Essex County, Mass., practised for a short time at Newburyport. Later he studied theology and in 1819 was ordained pastor of the Hollis Street Church in Boston. His outspoken views on temperance, anti-slavery and other reforms occasioned his dismissal from the parish in 1845, and he was subsequently pastor of Unitarian churches at Troy, N. Y., and Medford, Mass. His 'Airs of Palestine,' first issued in 1816, was republished in a volume entitled 'Airs of Palestine, and Other Poems' (1840). He also published 'Anti-Slavery Poems' (1843). One of his best-known poems is 'Warren's Address at the Battle of Bunker Hill,' and the pathetic lines on the death of his son are still remembered.

PIERPOUDRE COURT. See PIEPOWDER COURT.

PIERRÉ, pē-ār', S. Dak., city, capital of the state, county seat of Hughes County, alt. 1,470 feet, on the east bank of the Missouri River; on the Chicago and North Western Railroad, two federal highways and one state highway, near the central part of the state. It is in a farming and stock-raising region, rich in natural gas. Large shipments of livestock are made from here, and saddlery is manufactured. In the city are the State Historical Library, a government Indian Industrial School, and Saint Mary's Hospital (Benedictine Sisters). The settlement here (1880) was named from Fort Pierre, across the river; it was originally Port Pierre Chouteau, founded by the son of St. Louis's founder. Pierre became a city in 1883 and the capital in 1889. Pop. (1940) 4,322.

PIERREPONT, pēr'pŏnt, **Edwards,** American jurist and diplomat: b. New Haven, Conn., 4 March 1817; d. New York, 6 March 1892. He was graduated from Yale in 1837, admitted to the bar in 1840, established a law practice in Cincinnati, Ohio, where he remained until 1845, when he removed to New York. In 1847 he was elected judge of the Superior Court of New York, resigning in 1860. In 1862 he was appointed by President Lincoln to conduct with John A. Dix the trials of the prisoners of State, and in 1864 actively supported Lincoln in the Presidential campaign. He was prosecutor for the government of John

H. Surratt, indicted for complicity in the assassination of Lincoln, and in 1869–70 was United States district attorney for southern New York. In 1870 he was one of the committee of 70 which fought the Tweed ring, and in 1875 became Attorney-General of the United States, which office he resigned in 1876 to accept the appointment of Minister to England. He resigned this post in 1878, and resumed his law practice.

PIERROT, pē-ā-rō′, in France one of the characters that appear in pantomime. The pierrot is a cunning and shameless poltroon, whose delight is in mischief or roguery. His dress is white, very wide and loose, with huge buttons.

PIERS PLOWMAN. See LANGLANDE, WILLIAM.

PIERSON, pēr′sŏn, **Abraham,** American educator: b. Lynn, Mass., about 1641; d. Killingworth, Conn., 7 March 1707. He was graduated from Harvard in 1668, ordained in the following year, served in charge of various pastorates and in 1700 was one of the founders of Yale College, of which he became the first president in 1701. He remained in that office until his death in 1707.

PIERSON, Arthur Tappan, American Presbyterian clergyman: b. New York, 6 March 1837; d. 1911. Graduated from Hamilton College, Clinton, N. Y., in 1857, and was a Congregational minister until 1863, when he entered the Presbyterian body. He held many important pastorates in the United States, was pastor of the Metropolitan Tabernacle in London in 1891–93, and of Christ Church, there, in 1901–03. He is author of: 'Keys to the World' (1888); 'Heart of the Gospel' (1892); 'New Acts of the Apostles' (1894); 'The Gordian Knot' (1902); 'The Keswick Convention' (1903), etc.

PIERSON, Lewis Eugene, American financier: b. Metuchen, N. J., 12 March 1870. He entered the banking business in 1885, and became chairman of the board of the Irving Bank-Columbia Trust Company and director in many corporations. He also became chairman of the executive committee of the Chamber of Commerce of the United States, and was president of its board of directors, 1927–28. He has received decorations from France and Poland.

PIETER DE HOOCH (or **HOOGH),** pē-tér dè hōh (or hōg), Dutch painter: b. about 1630; d. about 1681. Little is known of his life and no portrait of him remains. Some contemporary Pieter de Hoochs have added confusion to the various printed accounts. His birthplace is unknown, but from documentary evidence he seems to have been living at The Hague from 1653 to 1655, where he was employed as servant to a merchant, Justus de la Grange and painted pictures as he had opportunity. He is recorded, 20 Sept. 1655 as a member of the Painters' Guild of Saint Luke at Delft. Two years later he is lost sight of and remains in obscurity until he is found in Amsterdam in 1668. Here he came under the influence of Rembrandt, an influence of highest importance to his art. No picture of de Hooch is dated later than 1677 and it is assumed that he died shortly afterward. He is a painter of genre subjects, choosing for the most part Dutch interiors, though there exist a number of exterior scenes — scenes of cottage life outdoors, where the landscape features are ably handled. Though several of his pictures exhibit animated groups of people, he for the most part relegates the human element to a subordinate position and paints sunlight as his principal object. His reputation has increased in recent years; the English, who possess many of his best works, being earliest in showing their appreciation. His greatest works are 'The Country House' and 'The Battery' in the Ryks Museum, Amsterdam; the 'Card Party' in the Louvre and the 'Dutch Interior' in the National Gallery. An 'Interior' is in the Metropolitan Museum, New York and other examples in the private collections of C. F. Yerkes of Chicago and H. O. Havemeyer, New York.

PIETERMARITZBURG, pē-tĕr-măr′its-boorg, or simply **MARITZBURG,** South Africa, the capital of Natal, situated on an elevated plain, 2,200 feet above sea-level, 70 miles by rail west-northwest of Durban, on the river Umsindusi, a tributary of the Umgeni. It is a thriving and pleasant town, well laid out, with broad streets, many planted with trees and lighted by gas and electricity. It contains several handsome public buildings including the Legislative Council building, in front of which is a white marble statue of Queen Victoria. Pietermaritzburg is the seat of an Anglican bishopric and among its churches are two cathedrals. Its educational institutions include a library, a small museum, Maritzburg College and several public schools, an Anglican college for girls and a Roman Catholic convent. The town has several reserves for recreation purposes, the chief being Alexandra Park. The Botanic Gardens are situated a short distance from the town. The extensive waterworks cost about $300,000. Fort Napier contains the barracks. The chief industries are the building of carts and wagons, tanning, brickmaking and brewing and there is some trade in hides, etc. Pietermaritzburg was founded by Boers in 1839 and derives its name from two Boer leaders, Pieter Retief and Gert Maritz. It was incorporated in 1854 and the railway was opened in 1880. The assessed valuation of realty is over $35,000,000. Pop. (estimated) 36,023, of whom 17,998 are white, one-fourth Asiatics and Indians and one-fourth blacks.

PIETISM, a religious movement in the Lutheran churches of Germany, which had its rise toward the end of the 17th century. Like Methodism and Methodist, Pietism and Pietist were originally terms of contempt bestowed on religious innovators by their conservative opponents. The author of the Pietist movement was Philip James Spener, a Lutheran pastor at Frankfort on the Main who in 1670 began to hold private conferences in his own house with devoutly inclined people, in which the Scriptures were explained with a view solely to the promotion of inward piety instead of the inculcation of dogmatic beliefs. In a book entitled 'Pia Desideria' (1675) he sought to bring the Lutheran Church back to its original principles. That Church, the foundation principle of which was, for Luther, Christian faith in the heart and acceptance of the Scriptures as the supreme rule of life and belief, had become a creed-bound institution with an inflexible system. In the pulpits the dogmas of the creeds

were continually expounded and defended, while the Bible was made of no account by preachers and pastors, in the theological schools or in the family. The true pastoral work of the Christian ministry, that of forwarding the moral and spiritual welfare of the people, was in desuetude. To remedy these evils Spener proposed in his work: (1) Cultivation of devout study of the Scriptures in private meetings; (2) Recognition of the Christian priesthood of all the faithful by giving to the laity a share in the government of the Church; (3) Insistence, in pulpit discourse, upon the necessity of vital personal piety; (4) Kindly persuasion instead of polemic bitterness in dealing with heretics and unbelievers; (5) Making theological seminaries schools of personal piety no less than of doctrine; (6) Banishing from the pulpit the tricks of rhetoric and substituting heart-to-heart hortation to Christian faith and love. The book made a deep impression throughout Germany among the devout laity and the more earnest clergy. Spener was the same year appointed court chaplain at Dresden and in that station was the means of bringing about a reformation of the system of catechetical instruction throughout Saxony. In the Leipzig University some of the students and docents of the theological school formed themselves into a society for study of the Scriptures both intellectual and devotional and those among them who were the more advanced conducted courses of practical exposition and application of the sacred text, to which students and townspeople resorted eagerly, so that the Church authorities were alarmed and the lectures were suppressed by the government. The young theologians thereupon left the university and the city and entered the new university just founded at Halle by friends of the new movement; thereafter Halle was the chief centre of Pietism. Like most other reformatory movements whether in church or state, its aims were from first to last condemned as impious or as seditious, but one by one they were adopted by their antagonists; Pietism as an organized movement subsisted till the middle of the 18th century; its monument was a state church reformed in nearly every particular in accordance with Spener's program. Consult Schubert, 'Outlines of Church History' (1907).

PIETISTS. See Pietism; Religious Sects.

PIETRA DURA, pē-ā'trä doo'rä, a mosaic executed in Italy and especially at Florence, in hard stones, such as topazes, garnets, carnelians, rubies, etc. Inferior kinds, in which imitation stones are used, are largely made in England.

PIEZOMETER, any of several instruments for measuring the compression of water and other liquids under pressure. They usually include a glass tube containing a compressible liquid, backed by a graduated gauge, like a thermometer. They are used for testing pressure in water-pipes, the compression of gas in a gun-bore, to discover deep-sea pressures, etc.

PIFFARD, Henry Granger, American physician: b. Piffard, N. Y., 1842; d. 1910. He was educated at the University of the City of New York and in 1864 was graduated at the New York College of Physicians and Surgeons. From 1875 to 1910, Dr. Piffard was professor of dermatology at the University of the City of New York, later known as New York University. He was renowned in the different fields of physics, botany, therapeutics and linguistics. He founded the Dermatological Society, translated Dartrous's 'Diathesis' (1868) and published several original articles mostly on professional topics.

PIG-IRON. See Iron and Steel Industry in the United States.

PIGAFETTA, pē-gä-fĕt'tä, **(Francesco) Antonio,** Italian explorer and historian: b. Vicenza, Italy, 1491; d. there, about 1535. He accompanied Magellan on his voyage around the world in 1519–23, and wrote the journal which constitutes the only history of the voyage which remains, as that written by D'Anghiera was destroyed during the storming of Rome in 1527. The first complete edition of this valuable work was published under the title, 'Primo Viaggio intorno al Globo Terracqueo' (1800).

PIGALLE, pē'gäl, **Jean Baptiste,** French sculptor: b. Paris, 1714; d. 1785. He studied under Robert le Lorrain and Lemoyne, and later at Rome. Pigalle was elected to the Academy in 1744; became professor there in 1752 and rector in 1777. His best work is 'Mercury Fastening his Sandal,' of which there is a replica in the Metropolitan Museum, New York. Other works are 'Child with Cage,' 'Love and Friendship,' busts of Guérin and Maurice of Saxony, all in the Louvre; 'Mercury' (Berlin Museum); 'Venus' (Potsdam); Louis XV monument at Rheims; 'Queen of Heaven,' marble group in Saint Sulpice, Paris; tomb in Notre Dame de Paris; statue of Voltaire in the Institut. Consult Tarbé, 'La vie et les œuvres de J. B. Pigalle' (Rheims 1859).

PIGEON, a general name applied to any species of bird of the family *Columbidæ,* or collectively to the entire group, or in an even wider sense to the whole order *Columbæ.* No sharp distinction can be drawn between the usage of the words dove and pigeon for birds of this group; though in a general way the former is applied to the smaller and more delicate, the latter to larger and more robust forms. In the articles Columbæ and Columbidæ will be found some account of the characteristics, distribution and chief groups of the pigeons, and under Dove descriptions of a few representatives of the smaller wild species. This article will be confined to a discussion of the origin, varieties and care of the domestic pigeons, and a brief account of a few of the native wild species to which the name "pigeon" most properly applies. Accepting the conclusions of Darwin, who investigated the subject extensively, ornithologists and fanciers trace the origin of all the numerous varieties of domestic pigeons to the common rock-pigeon (*Columba livia*) of Europe and North Africa. The ease with which many wild species of pigeons hybridize and produce fertile offspring is, however, well known; and there is much reason to believe that the strain of the domestic pigeons is not entirely pure, but has been mixed from time to time with certain Asiatic species, and especially with such true rock-pigeons as *C. leuconota* and *C. intermedia.* However, all of these forms are very closely related, differing in little besides color; and

there is no reason to doubt that *C. livia* is the predominant ancestral species.

Many individuals of the common dovecot pigeon — those of a grayish-blue color with white lower backs and two black wing-bars — very closely resemble the wild rock-pigeon. In the wild state the rock-pigeon inhabits the rocky sea coasts and neighboring islands of Europe and North Africa, but is rare inland; though in many places flocks of domestic pigeons have reverted to the feral state and have reacquired most of the characteristics of their wild ancestors. Indeed several of the so-called species found in various parts of Europe, Asia and Egypt are considered by Darwin to have thus originated. Like their domesticated descendants, wild rock-pigeons are gregarious and live in communities among the caves and fissures of inaccessible cliffs, where they associate with cormorants and other sea-birds. In the early morning they fly in flocks to the cultivated districts for the purpose of feeding upon grains and seeds. They also relish snails, insects and fruits. Except when with young, whose needs force them to return to the nesting site more frequently, they remain in the fields throughout the day. These pigeons are little, if at all, migratory, and during the winter congregate in larger flocks which search the farming districts for food. About April a simple nest of grass and twigs is constructed on a rock-ledge and two eggs are laid. After the young are able to leave the nest a second and perhaps a third pair is raised. They are strictly monogamous, and are said to mate for life. In movements, voice and other ordinary habits they resemble the common domestic pigeon.

Rock-pigeons take very kindly to domestication, and they, and perhaps closely related species, have been confined and bred for an immemorable period, not alone because of the very excellent quality of their flesh as food, but also as carriers of messages, and because of the interest attached to the remarkable and numerous varieties to which they give origin. It is, however, probable that pigeons were first domesticated solely for the purpose of supplying the table; at least the earliest known record, more than 3000 B.C., signifies their use for this purpose by the Egyptians. Several hundred distinctive varieties, of which about 150 are named and recognized by fanciers, have been produced under domestication, some of them differing but little, others to a marvelous degree, from the wild stock; many, indeed, are almost monstrous. Concerning the origin of many of the principal types of domestic pigeons, very little is known historically. Some of them, as the carriers or homing-pigeons, are certainly very ancient, and the Romans, who valued pigeons highly, had many races, the pedigrees of which were carefully recorded. Darwin based his conclusion that all this multitude of divergent forms could be traced back to a common ancestry in the rock-pigeon not only on the well-known facts of the ease with which the rock-pigeon can be domesticated, the resemblance in appearance, habits and voice between the common domestic pigeon and the wild rock-dove, and the geographical distribution of the latter, but also upon a most painstaking anatomical study of many varieties and of the facts of breeding and reversion. He noticed that triple crosses between distinct varieties of no matter what color were very likely to produce in the third generation a color pattern precisely like that of the wild race. The remarkable persistence of the white wings, which breeders find to be one of the most difficult features to breed out of fancy-colored strains, points to *C. livia,* of which this feature is a characteristic. Darwin's views have been generally accepted, as has his classification of the numerous varieties. Four principal groups are recognized: (1) The pouters, forming a very distinct race especially characterized by the enormously enlarged inflatable œsophagus and crop; (2) a group in which the beak is generally long (short in the barbs), the skin about the eyes and the base of the beak is rough, swollen and wattled, and the feet are large; in this group are included the various kinds of carriers, dragons, runts and barbs; (3) a group in which the beak is short and the naked skin about the eyes but little developed; Darwin considers this an artificial group and includes in it the fantails, owls and turbits, tumblers, frill-backs and jacobins, each representing a well-marked sub-group; (4) this group includes a great number of races more or less closely resembling the rock-pigeon, from which they have departed much less widely, and are consequently less highly valued by fanciers than the more strikingly modified races of the preceding groups. Among those which Darwin considers as belonging here are the trumpeters, laughers, nuns, spots, swallows and common dovecot pigeons, of which the latter stands nearest to the ancestral type. Next to the pouter the fantail is the most extreme modification, for its tail contains up to 36 or even 42 quill feathers, in place of the 12 originally present.

Concerning the care of pigeons a few general principles may be stated and the novice will avoid many difficulties by recalling the habits of the wild birds and not running counter to nature. In domestication a dovecote or loft is substituted for the rocky caverns of their native isles, but pigeons should have as much freedom as possible, with plenty of fresh air, light, clean food and water, and a clean and roomy shelter from the extremes of weather. Dirty, crowded quarters engender parasites; sour food and lack of air and light cause various diseases; lack of suitable shelter from the weather proves especially fatal to the young birds and nestlings. If possible, pigeons should be given the utmost freedom to fly and return at will; but, if for any reason this is inexpedient, a large flying-cage in the open air should be provided. The gregarious instinct is so strong in pigeons that birds continually desert a small flock in order to join a large one in the same neighborhood. For housing pigeons the loft is preferable to the cot or small house, for very many reasons. It should be a large, airy, well-lighted room, with suitable means for the ingress and egress of the pigeons, and capable of being divided in order to permit of the separation of the different races and sexes when desired. Easily cleaned nesting and roosting boxes may be arranged in shelves on the walls and during the breeding period should be provided with nesting saucers or pans, some clean, soft hay, and kept scrupulously clean. Pigeons do not dust, but are very fond of bathing, for which ample facilities should always be provided. The food best adapted to the hardier is not always

suitable to the more delicate varieties, which require a more dainty diet; but in general crushed Indian corn, wheat, peas and beans are the staples, the legumes especially for breeding birds. If they have no opportunity to fly in search of insects and snails a few of these or of earthworms should be occasionally added. A little salt, an abundance of ground oyster-shells or other calcareous material, gravel and drinking water are required. For the special requirements of the fancy varieties reference must be made to some of the special works on pigeon breeding.

Besides the fancy varieties raised in the United States, great numbers of the common sorts are bred for use at shooting-matches and for table consumption in the form of squabs. Most of the supply comes from the small lofts owned by numerous farmers and stablemen, but in a few places the business has been entered upon on a more extensive scale.

Besides many species known as doves, four species popularly designated as pigeons occur in the United States. Three of these belong to the typical genus *Columba,* to which the rock-pigeon belongs. These are the band-tailed pigeon (*C. fasciata*) of the Rocky Mountain and Pacific region, with a distinct sub-species in Lower California; the red-billed pigeon (*C. flavirostus*) from Arizona southward, and the white-crowned pigeon (*C. leucocephala*) of Florida and the West Indies. They all differ greatly from the rock-pigeon in habits, being wood-pigeons, which build their nests in trees and bushes, among whose branches they largely live, though they feed upon the ground on acorns, nuts, seeds, etc. They lay two eggs, like most pigeons, and are gregarious, the first especially often collecting in great flocks. Differing from all of these was the once famous passenger pigeon (*Ectopistes migratorius*), now believed to be extinct. It was distinguishable at a glance by its long tail composed of 12 slender tapering feathers. A large bird, from 16 to 18 inches long, its graceful form and beautiful metallic tints gave it an impressive appearance. It had no fixed place of abode, but wandered widely in great flocks (sometimes numbering in the billions) in search of food. It ranged throughout North America east of the Rocky Mountains, and occasionally made its way to the shores of the Pacific, but was most abundant east of the Great Plains and in temperate regions. From time to time passenger pigeons are reported to have been seen in different parts of the country, but the last known specimen died in captivity in the Cincinnati Zoological Park in 1914, and the last one actually identified in wild life was in 1907. See HOMING PIGEON.

PIGEON-BERRY, or **INK-BERRY.** See POKEWEED.

PIGEON ENGLISH. See PIDGIN.

PIGEON HAWK, a small falcon (*Falco columbarius*), distributed throughout the northern hemisphere. There are more than a dozen species scattered over the world, the two most common being the European representatives Hobby and Merlin; they prefer wooded cultivated districts, and usually follow in the train of the small migratory birds on which they prey; the flight is rapid and long sustained; the nest is made on trees or among rocks, and the eggs are from three to five. The American pigeon hawk is 12 to 14 inches long and about 25 in alar extent; the male smaller. The general color is bluish slate, every feather with a longitudinal black line; forehead and throat white; below pale yellowish or reddish white, each feather with a longitudinal line of brownish black; the tibiæ are light ferruginous, with black lines; quills black, with ashy white tips; tail light bluish ash, tipped with white, with a wide subterminal black band and several narrower bands of the same; cere and legs yellow and bill bluish; the variations in plumage, according to age and locality, are considerable. It is found over all temperate North America, Central and the northern part of South America, and breeds in the north. It is the boldest of any hawk of its size, pouncing on thrushes, wild pigeons, woodpeckers, snipe and even teals, but preying chiefly on birds of the size of the red-winged blackbird and sora rail. It rarely attacks poultry, yet has been known to seize cage-birds hung in the porches of houses even in crowded cities. The nest, placed in some thickly foliaged tree, is coarsely constructed of sticks and mosses, resembling that of a crow; the eggs measure about one and three-fourths by one and one-half inches, and are nearly spherical; the color is not a very clear white, and there are a few bold irregular dashes of light yellowish brown, chiefly about the smaller end.

The pigeon hawk, says Stejneger, is very closely allied to, if not identical with, the European merlin (*F. lithofalco*); these two forms, with the East Indian turumti (*F. chiquera*), and its South African race (*F. ruficollis*), are frequently regarded as a separate genus *Æsalon.* Consult Fisher, A. K., 'Hawks and Owls of the United States' (Washington 1893).

PIGEON-PEA, the fruit of the leguminous shrub *Cajanus indicus,* a native of India, but now cultivated in tropical Africa and the West Indies. There are two varieties, distinguished as *bicolor* and *flavus.* The former reaches a height of from three to six feet, and has yellow flowers with crimson markings; the latter is larger, sometimes attaining a height of 10 feet, and its flowers are of a uniform yellow color. In India the pigeon-pea forms a pulse of general use. The former variety is called also Angola pea and Kongo pea.

PIGEONS, Clay. See TRAP-SHOOTING.

PIGLHEIN, pēg'l-hīn, **Bruno,** German painter: b. Hamburg, 19 Feb. 1848; d. Munich, 15 July 1894. He began his study of painting in the studio of Lippelt in Hamburg. Going to Dresden in 1864 he attached himself to Schilling, with the idea of becoming a sculptor, but in 1870 returned to painting, which he studied under Pauwels in Weimar, and in Munich under W. Diez. The series of decorative works and mythological genres which he soon afterward produced show the influence of Böcklin (q.v.) and Makart. He first became widely known by his 'Moritur in Deo' (the dying Christ supported by an angel), now in the Berlin National Gallery. He then executed a series of drawings in pastel,— busts, heads and half-lengths of ladies of fashion, rakes, dandies and children,— which appeared at Munich (1884) under the title 'Douze Pastels.' His genre pictures of child life are well known through the reproductions of his illustrations to the idyll 'Kind mit Hund.' In 1885 he undertook a journey to Palestine with the object of collecting materials for a panorama of 'the Crucifixion,' which he completed with the assistance of several other artists and exhibited in 1886. It was afterward reproduced in wood cuts 1887, but the original was destroyed by fire at Vienna (1892).

PIGMENT (old French), any substance that is used or can be used by painters. The word comes indirectly from the Latin *pigmentum,* and is related to paint and painting. The Picts of Scotland were so called because they painted themselves. Technically a pigment is a dry substance that can be easily pulverized if it be not already in the form of powder. But the term has been extended so as to include mixed paint ready to be applied.

In biology the word pigment is used in the sense of organic coloring matter; that is organized substances in the tissues of animals and plants giving them color. This coloring matter or pigment is very generally distributed throughout the animal and plant kingdoms, the absence of color in any of them or of their parts being very rare. The darker or lighter color of the skin in different races is due to the presence of more or less heavy pigmentation of the choroid. In many plants and animals the pigment color characterizes the genera, or family. This is especially noticeable in the lower forms of animal and plant life.

A highly spiced wine sweetened with honey is also called pigment. See COLOR.

PIGMENTS, Animal. See COLORATION, PROTECTIVE.

PIGMY. See PYGMIES.

PIGNUTS. See HICKORY.

PIGOT, SIR Robert, British soldier: b. Patshull, Staffordshire, 1720; d. there, 2 Aug. 1796. Entering the army as a boy, he served at Fontenoy, was colonel in 1772, accompanied the 38th foot to Massachusetts, fought at Lexington, 19 April 1775, and 17 June commanded the British left at Bunker Hill, becoming colonel of the regiment in December of the same year and major-general in 1777. He was stationed in Rhode Island in the next year, and in 1782 became lieutenant-general. In 1778 he succeeded his brother as baronet and became part owner of the Pigot diamond, brought by his brother from India; it was raffled for in 1800, the receipts being nearly $120,000 and in 1802 was sold for $150,000 to Ali Pasha, who had it ground to powder in 1822, when he was mortally wounded by Reshid Pasha.

PIGRIS, a Greek poet, brother of Artemisia, queen of Caria (352–350 B.C.). Modern critics assign to him the authorship of the famous mock epic, Βατραχομυομαχια, 'The Battle of the Frogs and Mice,' a work formerly accredited to Homer.

PIGWEED. See GOOSEFOOT.

PIKA, a small animal of the higher mountains of the northern hemisphere, representing the family *Lagomyidæ,* and closely allied to the hares, of which it seems a degenerate branch. The pikas differ from the hares in their much smaller size, in the nearly equal length of the fore and hind legs, in the short, rounded ears, the very small size or absence of the tail, and in the possession of nearly complete clavicles or collar-bones. In their most southern distribution they inhabit the mountainous districts and highlands, well-known species being numerous on the mountain tops of the European Alps, in the Himalayas and in the Rocky Mountains. They are never seen below timber-line, but are found far above it, in Ladak to the altitude of 16,000 feet. They dwell in underground burrows, or among the loose fallen rocks of a slide or cliff-talus, where large communities occupy favorable places. To this they owe the name "coney," commonly given to *Lagomus princeps,* the best-known American species, which the Indians called "little chief." The European name, "calling" or "piping" hare, refers to the shrill, piping bark. They feed upon herbage during the summer, and in the early autumn cut and dry a great quantity of this, which they take into their deep burrows as provender for the winter. Their fur is exceedingly warm and close, and was utilized by the American Indians as material for underclothing, infants' garments, etc. About 16 species are known. Consult Blanford, 'Fauna of British India Mammals' (1888); Stone and Cram, 'American Mammals' (1902).

PIKE, Albert, American author and lawyer: b. Boston, Mass., 29 Dec. 1809; d. Washington, D. C., 2 April 1891. He was educated at Harvard, engaged in teaching, in 1831 accompanied an expedition to Santa Fé, afterward exploring the head-waters of the Red and Brazos rivers, and in December 1832 settled at Fort Smith, Ark. He edited the Arkansas *Advocate* in 1833–36, was admitted to the bar and engaged in law practice. In the Mexican War he commanded a squadron, fought at Buena Vista, received the surrender of Mapimi in 1847, and during the Civil War was Indian commissioner of the Confederate government, and later brigadier-general. After the war he practised in Memphis and in Washington, edited the Memphis *Appeal* in 1867–68, and engaged in literary work. His 'Hymns to the Gods,' published in *Blackwood's Magazine* in 1839, gained for him a reputation as a poet, and besides 30 volumes of Masonic works he published 'Prose Sketches and Poems' (1834).

PIKE, Robert, English colonist in America: b. England, 1616; d. Salisbury, Mass., 1706. He came to America in 1625, from 1629 resided on a farm at Salisbury, Mass., and from 1644 until his death held public office in a colony. He is distinguished for his liberal attitude on various questions of colonial interest. Thus, though a believer in witchcraft, he opposed the admission in court of «spectre» testimony; and though a strictly orthodox Puritan, defended the Quakers, and censured the general court for its position in the matter. In these questions he appears as one of the earliest exponents in America of the sentiment toward free speech, criticism, and petition of legislative assemblies, and acquittal in courts of law in default of sufficiently conclusive evidence.

PIKE, Zebulon Montgomery, American soldier and explorer: b. Lamberton, N. J., 5 Feb. 1779; d. York (Toronto), Canada, 27 April 1813. He was the son of an army officer, into whose company he volunteered, serving as a cadet when only 15, and becoming a first lieutenant six years later. In 1805 after the Louisiana Purchase he was ordered to trace the upper course of the Missouri, and with 20 men spent nearly nine months on the dangerous voyage to Red Cedar Lake. Immediately upon his return he was commissioned by General Wilkinson to lead a party through the centre of the Purchase. This expedition was overtaken by winter and the party, while on the banks of what they thought the Red River, was arrested by the Spanish authorities, who later released all members of the expedition. Before his arrest Pike had discovered «Pike's Peak» and had explored the country around Leadville. He arrived at Natchitoches 1 July 1807, was warmly thanked by his superiors, and was rapidly promoted. In 1812 he was stationed on the frontier, and in the next year, having become a brigadier, led the attack on York, Canada. The magazine of the fort exploded during the assault and Pike was killed by a flying stone. The fort surrendered just before he died. Consult Cones, E., 'Expedition of Zebulon M. Pike to the Headwaters of the Mississippi' (3 vols., New York 1895).

PIKE, a weapon much used in the Middle Ages as an arm for infantry or foot-soldiers. It was from 16 to 18 feet long, and consisted of a pole with an iron point. (See LANCE). Men armed with it were called pike-men. After the invention of guns, pikes gradually fell into disuse, the bayonet in the musket or rifle being more suited to hand-to-hand fighting. The Prussian Landsturm was armed with pikes in 1813, to be used in case no better arms were to he had. The Swiss first substituted the halbert for the pike toward the 15th century. For some time every company in the armies of Europe consisted of at least two-thirds pike-men. In the United States during the John Brown (q.v.) insurrection at Harper's Ferry, Va., Brown's followers were armed with pikes as well as muskets.

PIKE, PICKEREL, fresh-water, ravenous fishes of the family *Luciidæ* or *Esocidæ*. They are teleostomous fishes, forming, with the mud-minnows, cyprinodonts and blind fishes, the order *Haplomi*. In the pikes the body is lengthened, flattened on the back, and tapers abruptly toward the tail. One dorsal fin exists, placed far back on the body, and opposite the anal fin. The mouth is very large and lower jaw projects, the biting edge of the upper jaw being formed by the maxillary and premaxillary bones. Teeth are present in plentiful array, and are borne by almost every bone entering into the composition of the mouth as well as small ones upon the tongue. They are very sharp and of various sizes, the larger ones having a hinge-like attachment by means of a ligament, to the bones. The body is clothed with small cycloid scales, or those of a simple rounded variety. There is a single genus (*Lucius*) with five species, four of which are confined to North America, the fifth being found in Europe and Asia also. The common pike (*Lucius lucius*) occurs in the rivers of Europe, northern Asia and North America. Pikes are the tyrants of their sphere, being the most voracious of fresh-water fishes. They feed upon smaller fishes, upon frogs, muskrats, and other animals; and young ducks and other aquatic birds have been known to be dragged below the water and devoured by these fishes. Perches and sunfish are said to escape the pike's attack owing to the presence of their spiny dorsal fins. When fully grown the pike may ordinarily attain a length of four feet, and there are instances on record in which these fishes have exceeded that length.

In America this species ranges from the Ohio River and southern New York to Alaska and Greenland, and is especially abundant in the lakes and rivers of British America. It prefers quiet waters; and remains for long periods suspended perfectly stationary in the water, but, when its prey approaches, darts upon it with the utmost suddenness and the speed of an arrow. Throughout the year, except in the spring when they consort in pairs, the pike leads a solitary life; 100,000 to 500,000 eggs are deposited from April to May, according to the latitude. No nest is made, and the non-adhesive eggs sink to the bottom. The muskellonge or muscalonge is a still larger species, often attaining a length of five to eight feet and a weight of 100 pounds or more. It may be quickly distinguished from the pike, with which it is often confused, by the absence of scales from the lower part of the cheeks and the greater number of rays in the fins. It is found in the Great Lakes and other large bodies of water in that general region and northward. Being a pike on a large scale, its habits closely resemble those just described for that species. It prefers the deeper waters, resting among plants near the bottom and is a most formidable enemy of all living creatures inhabiting the same waters.

The name «pickerel» is the diminutive of pike and is employed to designate all of the small species as well as the young of the larger. The species to which this name is especially applied are the banded pickerel (*L. americanus*), which seldom exceeds 12 inches, and is found in lowland streams of the Atlantic watershed from New England to Florida; the western pickerel (*L. vermiculatus*), a similar species of the Mississippi Valley; and the common pickerel, pike, or jack (*L. reticulatus*) of the entire eastern United States. The last named attains a length of two feet and is common everywhere, being especially abundant in clear lakes, where it reaches the largest size.

All of these are most excellent table fishes. The dash with which they take the hook, and the vigor and determination with which they fight for liberty makes them great favorites with sportsmen, though their destructiveness to other game fishes has gained them many enemies. The larger species, and especially the muskellonge, are usually taken by trolling, a copper wire line being used when they seek the depths of the lakes. The smaller ones may be taken with a light tackle, the chief precaution being to provide against the severance of the line by their sharp teeth. Live minnows or small frogs are tempting baits.

The name pike is also used for several other quite unrelated fishes which present some resemblance to the pikes in their elongated forms. Among these may be mentioned the gar pikes (*Lepidosteus*) and the sea pike or silver gar (*Tylosuras*). Consult Henshall, 'Bass, Pike, Perch and Others' (New York 1903); and Cholmondeley-Pennell, 'Book of the Pike' (New York 1890).

PIKE-PERCH, a fish closely allied to the perch, but showing a resemblance to the pike in the elongated body and head. The American pike-perches belong to the genus *Stizostedion,* which differs from the European *Lucioperca* in the weaker development of the fin spines. From the true perches the pike-perches are easily distinguished by the elongated head and the presence of canine teeth on the jaws. The most important species is *S. vitreum,* which bears a large number of local names, but is best known as the wall-eyed pike (q.v.). The chief European species is *L. sandra,* which attains a length of three or four feet, and weighs 25 or 30 pounds. The *S. canadense* inhabits many of the northern lakes of North America, and is slightly more cylindrical than *S. vitreum,* besides having more spots on the fins and no black spots back of the dorsal fins.

PIKE'S PEAK, in Colorado, a peak of the Rocky Mountains, lat. 39° N., long. 105° W.; the height is 14,109 feet above sea-level. Gen. Z. M. Pike, of the United States army, discovered this mountain in 1806. Colorado Springs, a famous summer resort, is near by. In ascending the mountain the transition is abrupt from pine forests, which cover the sides up to nearly 12,000 feet in height, to bare granite rocks with here and there tufts of sage grass in the crevices and at the summit, fringing the snow fields, plants with pale yellow and delicate purple blossoms. Two gorges extend from the top almost to the base. The summit is nearly level, with an area of about 60 acres. From the top may be seen a view of unsurpassed magnificence and grandeur; for fully 100 miles in all directions is a vast expanse of mountains and valleys, dotted with sparkling lakes and rivers. From 1873 to 1888 the United States Signal Service had here a meteorological station. The weather bureau established a station here in 1892. In 1891 a rack and pinion road was opened from Manitou Springs to the summit. An excellent automobile highway also affords access to the top of the peak.

PILASTER, *in architecture,* a column set in and partially projecting from a wall, as an ornamental support to an arch, etc., and seldom projecting more than one-fourth or one-third of its breadth from the wall. It may be a simple square support, or of any of the common orders of architecture, with capital.

PILATE, pī'lạt, **Pontius** (PONTIUS PILATUS), the Roman governor (procurator) of Judæa, Samaria and Idumea at the time of Christ's crucifixion: he held that station from the year 26 till he was deprived of office in 36: the capital of the district ruled by him was Cæsarea, in earlier times known as Turris Stratonis. Little or nothing is known regarding his history previous to his appointment as procurator. He was a man specially unfitted by temperament for the station to which he was assigned, in view of the keen animosities existing for ages between the Jews, the Samaritans and the ancient inhabitants of Philistia, and the abhorrence of the Jews for their Gentile rulers. Pilate flaunted in the face of the people of the Holy City the standards of the Roman armies with the image of Tiberius and the eagles of the legions, both of which were always saluted with religious veneration as gods; he rifled the sacred treasury (*corban*) of the temple to pay the cost of an aqueduct; he slaughtered a company of Galileans while they were engaged in an act of sacrifice; he set his troops upon a peaceable assemblage of Samaritans on Mount Gerizim, the holy place of that nation; it was this act, not his surrendering Jesus into the hands of his enemies in violation of Roman justice and simple humanity, that led to his being deprived of office. Eusebius adds that he was banished to Vienna (Vienne) in Gaul and that he died by suicide. But legend does not treat his story so prosaically; one legend makes him die at Rome where his body, having been thrown into the Tiber, caused violent tempests and inundations; but the patrons of the Vienne tradition make Vienne and the river Rhone the theatre of these prodigies. Strangely, Tertullian holds Pilate to have been at heart a Christian (*pro sua conscientia christianus*); the Copts reckon him among the martyrs, and he has a place in the Abyssinian Church calendar. Pilate's wife, traditionally named Procla, or Claudia Procula, is venerated in the Greek Church as a saint; her day in the Greek Church calendar is 27 October. Consult the apocryphal 'Acts of Pilate'; Rosadi, G., 'The Trial of Jesus' (London 1905).

PILATUS, pē-lä'toos, **Mount,** in Switzerland, a peak of the Bernese Alps, near Lake Lucerne. The highest crest, Tomlishorn, is 6,998 feet above sea-level. A rack and pinion railroad extends to the summit. The name seems to have come from the word *pila,* a pillar, hence, "pillar mountain." Some authorities claim the name comes from *mons pileatus,* "hatted mountain," from its appearance when the mists or clouds are rising. One of the numerous legends connected with the place is that it is named after Pontius Pilate, who from the top of this mountain threw himself into a lake and was drowned. Allusion is made to this legend in Scott's work, 'Anne of Geierstein.'

PILAU, pĭ-lä', or **PILLAF,** a food preparation common in Turkey, Egypt, Syria and India, consisting generally of rice, thoroughly boiled, drained, and gently stirred with butter, pepper and finely-chopped onions. For the tables of the wealthy, fowls, lamb, mutton, shreds of ham or bacon, variously cooked, but

always well boiled or roasted, are placed on the top of the rice, and served with it.

PILCHARD, a European herring (*Clupea pilchardus*), the full-grown form of the sardine (q.v.), which closely resembles the ordinary herring but is of smaller size and straighter outlines. This species is found in greatest plenty on the southern coasts of England, the Cornwall pilchard fisheries being those best known and most celebrated. The fishery is more or less continuously carried on, but proceeds with the greatest vigor in July. Shoals of pilchards then appear, which are taken in seines in vast amounts. More than 10,000 hogsheads, each holding 3,000 fish, have been filled in a single day's fishing at one port. These fishes are salted and cured, and are then piled into great stacks, from which a valued oil exudes. They remain four weeks in these stacks, and are then washed to free them from the oil, packed in barrels, and afterward exported. The pilchards are chiefly consumed in Spain, Italy and France during Lent and other fasting seasons.

PILCOMAYO, pēl-kō-mī'ō, a South American river, one of the affluents of the Paraguay, rising in the Bolivian plateau east of the Andes from several small streams in the districts of Lipez, Chichas and Poopo. Its general course is southeast, and its length perhaps 1,300 miles. It receives the Potosi and the Cachimayo; crosses the department of Potosi, Sucre and Tarija; joins the Pilaya, which drains southern Bolivia, above San Francisco Solano; and near that mission is joined by the Chaco. Its course so far is narrow, winding, and full of rapids and cascades, and its drop has been from a height above the sea of 6,500 feet to only 1,300 feet. But on coming into the flat country it does not become a navigable river, but like many of the Western rivers of the United States almost disappears in the sands and then spreads out in shallow lagoons, so that the embouchure of its main branch into the Paraguay is a forest swimming in a lake delta. Other branches join the Paraguay farther south than Asuncion, where the main branch empties. The main branch was a subject of dispute between Argentina and Paraguay, as the boundary was defined simply as being the main branch of this river. The Spanish explorers had considered it to be the Araguai Guazu (or Rio del Instituto Argentino); but a board of arbitration of which Rutherford B. Hayes was president decided against this claim in 1878. Fishing in the river is excellent. Exploration was begun by Father Patino in 1721. In 1882 Crevaux, a French explorer, was killed with five of his comrades by the Toba Indians.

PILE, or **SPILE,** in engineering and building, a heavy beam or timber, driven into soft ground, sand, mud, etc., to form part of a solid foundation for a building, wharf, wall, etc. The word comes from Anglo-Saxon *pil,* a sharp stake, which is also represented in modern English by the word *pale,* as a fence-pale. A pile is usually a portion of a straight tree trunk, from six to eight inches diameter at the smaller end, which is sharpened to a point, to drive easily into the ground. Sometimes this point is armed or protected with iron or steel, to prevent the wood from splitting in going down into hard ground. A pile may be of any length that can be conveniently handled, but from 20 to 60 feet is the usual thing. A series of them driven into a muddy bottom on a shore make a very firm support for a building. As wood becomes scarcer, the concrete pile has come into use, being a light shell of steel, filled with concrete. In some instances, as for steadying the tubes of the Pennsylvania railway tubes under the Hudson River, screw piles have been preferred, these having a very broad screw-like flange at the foot, which resists motion in any direction. They are put into position by turning like a screw, whereas the common pile is driven by a pile-driver. See FOUNDATION.

PILE, a primitive form of electric battery, made of plates piled up, as a dry pile, voltaic pile or thermopile. See ELECTRICITY.

PILE-DRIVER, a machine for driving piles or spiles. A tall framework carries a heavy weight sliding between guides and controlled by a rope. The pile being adjusted in position, the weight is dropped on the head of the pile, thus hammering it down, until the desired level is attained. A hoisting engine may be employed to raise the weight, and it may be given added force for its blow by a steam piston, on the principle of a steam hammer.

PILE-DRIVING. See FOUNDATION.

PILE-DWELLINGS, See LAKE-DWELLINGS.

PILES. See HEMORRHOIDS.

PILEWORT, a plant regarded as curative of piles. In Great Britain these virtues and the name belong to the celandines (q.v.), especially *Chelidonium majus.* In the United States several herbs of medicinal repute are called pileworts, such as the Maryland figwort (*Scrophularia marylandica*); the fire-weed (*Erechtites hieracifolia*), a thistle; and a crowfoot, the so-called lesser celandine (*Ficaria ficaria*).

PILGRIM, Charles W., American physician: b. Monroe, Orange County, N. Y., 1860. He received his medical degree from New York University in 1881 and pursued his studies further at the University of Vienna. In 1882 he was assistant physician in the asylum for insane criminals at Auburn, and occupied a similar position later at the Utica State Hospital and at the Women's Hospital at Munich, Germany. In 1890 he was appointed superintendent of the Willard State Hospital, and three years later became head of the Hudson River State Hospital. In 1906 he became president of the State commission in lunacy, which office he resigned in the following year to resume his work at the State hospital. In 1916 he was appointed chairman of the State hospital commission; and after 1921 has directed a private sanitarium.

PILGRIM FATHERS. See MAYFLOWER, THE.

PILGRIMAGE OF GRACE, in English history, an insurrectionary movement in 1536–37, consequent upon the proceedings of Henry VIII in regard to the Church, and led in the first instance by Robert Aske, a Lincolnshire gentleman. The insurgents demanded the fall of Cromwell, redress to the Church, and re-

union with Rome. Mustering to the number of 30,000, they marched upon York, and within a few days were masters of England north of the Humber. Henry temporized, promising a free parliament at York; but when the insurgents returned home all concessions were revoked, and a renewal of the revolt was suppressed with great rigor. Many perished by the block, the gibbet and the stake. See ENGLAND.

PILGRIMAGES, journeys to distant places for devotional purposes. The custom of pilgrimage is ancient and, until modern times, was universal. In ancient Egypt and Syria were privileged temples to which devotees resorted from distant parts. Pilgrimage is an important element in the religions of India. In the period of highest Grecian culture, whether in Greece itself or in Asia Minor or in Magna Græcia, the chief temples of the Hellenic gods were the resort of pilgrims in thousands; the temple of Athenē at her own city, that of Zeus at Olympus, that of Æsculapius at Epidaurus, of Hera at Samos, of Artemis at Ephesus, were for the Greeks what the temple at Jerusalem was for the people of Israel, or what Mohammed's tomb is for the Moslems. "We are only stirred," says Cicero, "by the very places that bear the footprints of those we love or admire." The pilgrimages of the Jews to their holy city at the high festivals were matter of precept; in Christianity, though pilgrimages have never been commanded by the Church, the custom of pilgrimage has had a vast development, beginning probably in the first Christian Age, and certainly attaining considerable proportions in the century which saw the triumph of the new religion over Roman paganism. Among the works of Saint Jerome (340–420) occur letters of his correspondents in Syria, the ladies Paula and Eustochium, in one of which the resort of numerous pilgrims to the holy places in Palestine is recorded in terms which give proof that in that day pilgrimage was a highly esteemed form of devotion, though the historical accuracy of the statement that pilgrims had flocked to the scenes of Christ's life "ever since the ascension" is open to question. "It were irksome," the lady Paula writes, "to count the bishops, the martyrs, the masters of ecclesiastical learning, who from the Lord's ascension till this day have come to Jerusalem, thinking that they would have less devotion, less knowledge; that their virtues would lack their last perfection, unless they should have worshipped Christ at the very spot where first the gospel light beamed forth from the gibbet." We learn from Saint Augustine and some of his contemporaries that the tomb of the protomartyr, Saint Stephen, attracted in his time great throngs of pilgrims. But it was in the Middle Ages that pilgrimage had greatest vogue. For some time after the Saracens had become masters of Palestine the pilgrims from the West had unhindered access to the holy places; but when Jerusalem came under the control of the fanatical sect of the Fatimites, Christian devotees were made the victims of all forms of outrage. After enduring this for about two centuries the Western world poured out its hosts of armed pilgrims, the Crusaders. But Palestine did not comprise all the places of pilgrim resort: near the city of Rome is Loreto, believed to contain the very house in which Jesus and his mother lived; Spain had the shrine of Saint James (Santiago) de Compostella; France that of Saint Martin of Tours. In the year 1428 there sailed from nine different ports of England for Spain on the way to Compostella 866 pilgrims; at the same time there were several famous shrines in England itself, chief among them the shrine of Saint Thomas á Becket, archbishop of Canterbury, one of the most celebrated resorts of pilgrims. In the latter half of the 19th century there was a revival of the custom of pilgrimages, especially in France. The most persistent pilgrimages of modern times are those of Islamites to Mecca (q.v.) and Medina (q.v.). These two Arabian cities live almost wholly off the pilgrims who come in vast numbers. Mecca is the sacred city, but the bones of the Prophet lie in a mosque at Medina, so thousands of the faithful deem it incumbent on them to visit both cities.

PILGRIM'S PROGRESS, The. This is an allegory of the life of man, the journey of the awakened soul to God. Crying "What shall I do?" Christian flees from the City of Destruction, puts aside his jeering or pitying neighbors, struggles through the Slough of Despond, trembles under Sinai, is comforted and instructed at Interpreter's house, and losing his burden at the Cross, is ready for the great journey. He fights against Apollyon, is imprisoned with Faithful in Vanity Fair. Escaping both seducers by the way and the clutches of Giant Despair, he gains those Delectable Mountains whence, though Atheist and Ignorance intervene, the way to the Celestial City is sure, even through the river of Death. Though the conception of human life as a hard journey toward the divine is both old and common, it has nowhere else been imagined so appealingly. This is not critical opinion; it is fact. The 'Pilgrim's Progress,' translated into all languages, has had a circulation beyond the possibility of record. It is one of the few instances, not merely of international fame, but of international popularity. Its characters have become proverbial; and the Slough of Despond and Vanity Fair are used almost as common nouns.

Popularity so wide must have its springs very deep. Surface reasons explain merely the occasion. Bunyan was a Dissenter in the time of the Protestant revolt. Born eight years after the Pilgrims landed at Plymouth Rock, he was a lad during the Civil War (1642–46), a young man under the Commonwealth and in his manhood 12 years a prisoner for insisting on liberty of preaching. He spoke to English Protestants on both sides of the Atlantic in their own religious language. But since his appeal has been limited neither to English nor to Protestants, we must look deeper. The persons of the 'Pilgrim's Progress,' Mr. By-Ends, the brisk lad Ignorance, Faithful and the rest, though they bear abstract names, are not mere personifications. They are more than the types of ordinary allegory, more even than the picturesque figures of the 'Faery Queene.' They are individuals, as truly characters as the persons of plays and novels. They talk as real people. We get from them what we desire of all imaginative literature, vicarious experience of human life.

The life that Bunyan thus creates by force

of imagination he knew by direct contact. It is common life because he was a man of the people. An unschooled tinker, mending pots and pans from door to door, he knew the common hopes and loves and fears by daily hard experience from childhood. That tells why he speaks the common language, a language so common as to be sometimes illiterate; it does not yet tell why he speaks the universal language. Bunyan happened to be a tinker; he was born to be a preacher; he became a great preacher because he developed to an extraordinary degree imaginative vision. Such of his actual sermonizing as has been imperfectly preserved, or is suffered to interrupt the story of the 'Pilgrim's Progress,' shows little beyond the disputatious habit of his sect. It is not characteristic. Bunyan cannot be reduced to sermon heads; for he was not a reasoner. But he was all the more a popular preacher; for his persuasion sprang from imaginative oral realization. He pictured vividly in his own mind both things and thoughts; he had a seeing imagination. And to an equal degree he had the power of oral utterance in words that would make his hearers see and feel too. Thus his diction is habitually concrete because for him to think was to see. He makes doubt, fear, repentance real by making them visible and almost tangible. He makes us live them in the persons of his story, feel them with him because we see them with him.

The other mainspring of his appeal is a style more utterly oral than that of any other English author. He follows with fearless simplicity the ways of common speech. The proverbs that he uses so often — "a saint abroad and a devil at home," "a waterman, looking one way and rowing another" — are no more homely than his own habitual expression. "There is a company of these crazed-headed coxcombs that when they take a fancy by the end are wiser in their own eyes than seven men that can render a reason." "Some cry out against sin even as the mother cries out against the child in her lap, when she calleth it slut and naughty girl and then falls to hugging and kissing it." Knowing few books but the English Bible, he has the cadences not of literature, but of talk. His style is as oral as any that was ever put into a book.

But deeper even than his vivid concreteness and his oral homeliness is the spring of his sincerity. His style is the pure expression of his own intense experience. His power still to stir men's souls wells from the agonies and triumph so vividly described in his 'Grace Abounding,' from his going down, as he says, into the deep, his enlarged spiritual capacity. The crowning merit of the 'Pilgrim's Progress' is that it cannot be long thought of as a work of art, that it makes us forget its style for its summons from the deceptions of things seen to the eternal unseen. Born an artist, Bunyan with single mind devoted his art to the glory of God and the salvation of men. His expression of the spiritual world is most simple and homely because he himself was simpler and homelier than any other Englishman who ever took a pen; but it is most intense because he himself was a fellow citizen with the saints.

CHARLES SEARS BALDWIN,
Late Professor of Rhetoric and English Composition, Columbia University.

PILIDIUM. See LARVA.

PILL, a form of prepared medicine consisting of a small globule convenient in size for swallowing. The ordinary weight of a pill is five grains. Some vegetable substances used as medicines may be made into pills without the addition of any other material, but usually the substances having medicinal properties are not of the proper consistence to be made into pills by themselves and require the addition of some other material, which is called an excipient. The usual excipients are bread-crumbs, hard soap, extract of licorice, syrup, molasses, mucilage, castor-oil, honey and conserve of roses. The last-named of these is especially valuable, as it preserves for a long time the proper consistency of the pills. The materials of which pills are made are mixed together until they are perfectly homogeneous and are afterward separated into pills with instruments or machinery devised for the purpose. To prevent them from adhering to one another, as well as to some extent to conceal the taste, they are covered with some fine powder, such as licorice-powder, wheat-flour, fine sugar and lycopodium. Immense numbers of pills are made by machinery and it is very common to coat them with sugar, gelatin and other substances, which are flavored and colored in various ways. Pills also sometimes receive a thin coating of gold or silver. The pill is a highly suitable form for administering medicines which operate in small doses, or which are intended to act slowly, or not to act at all until they reach the lower intestines and especially convenient in the case of substances which are strongly offensive to taste or smell. So common has the pill become for the administering of a cathartic, that pill is often synonymous for cathartic or physic.

PILLAF. See PILAU.

PILLAR, an upright, free, supporting member used in building, of any shape in section and thus to be distinguished from the column which follows the classical rules, being usually circular with a capital, while a pillar is plain and of any cross-section. The pier is heavier and broader than the pillar and usually of masonry. The term pillar is applied to the supports left for the roof in mining excavations and their rude form perhaps typifies the first step in this architectural usage.

Among the earliest peoples of which we have record the Egyptians used the pillar as an architectural member. In the remains of tombs at Beni-Hasan and elsewhere are found two types of pillars. One called the Proto-Doric is found in front of a tomb having a portico-in-antis of two columns. The resemblance of this pillar to that afterward developed by the Greeks has given it its name. The other type has received the name of lotiform from the fact that it seems to resemble a bundle of four lotus stalks bound together near the top. Above the ligature is carved the conventionalized lotus bud to form a capital. This pillar, no doubt originally constructed of wood, was adopted as the favorite order of later Egyptian builders.

A single column, as a monument, has occasionally been termed a pillar as Pompey's Pillar. See ARCHITECTURE; COLUMN.

PILLAR SAINTS (Greek, *stylitai*), the name of a class of hermits in Syria and Pales-

tine who from the 5th to the 12th century lived on the summit of pillars in the open air. The earliest was Simon Stylites, who in 420 invented this new kind of asceticism, professing a desire to do public penance and make vicarious atonement for others' sins. Accordingly he built a pillar 18 feet high and 3 feet wide at the summit. This he eventually raised to 60 feet high and 6 feet broad. There he lived for 37 years. His example was widely followed by a succession of hermits who, however, died out before the beginning of the 13th century.

PILLARS OF HERCULES, also called **PILLARS OF MELKART,** the latter being the Phœnician name: the peaks on either side of Gibraltar (q.v.), near which was planted the colony of Gades, now Cadiz. The Greeks, identifying the god Melkart with Hercules, their own guardian of travelers, called the place the Pillars of Hercules. See CALPE.

PILLING, James Constantine, American ethnologist: b. Washington, D. C., 1846; d. 1895. He received his education at Gonzaga College, Washington, and in 1872–79 was a member of the Rocky Mountain Geological Survey with Major J. W. Powell. This expedition afforded Pilling an excellent opportunity to study the Indian dialects of the region. He became chief clerk of the Bureau of Ethnology in 1879 and two years later was made chief clerk of the United States Geological Survey. He published bibliographies on several Indian languages and a general work under the title, 'The Languages of the North American Indians' (1885).

PILLNITZ, a palace of the former king of Saxony, on the right bank of the Elbe, seven miles from Dresden. The court remained here for some time each year. Pillnitz is famous for a meeting of the Emperor Leopold II, Frederick William II of Prussia, the Count of Artois, the ex-minister Calonne and several other personages, from 25 to 27 Aug. 1791. A treaty of offensive alliance was not concluded, but preliminaries were agreed on for a defensive alliance between Austria and Prussia, which was settled at Berlin, 7 Feb. 1792. The French were greatly irritated by this convention, which they considered as the basis of the coalition of Europe against France.

PILLORY, an old-time mechanism for punishment, consisting of a frame of wood erected on short posts, with a movable board in which were openings of a size suitable to confine the neck and wrists of the offender, who was thus helplessly exposed to any ill-considered outrage by passers-by, in a manner at variance with later ideas as to punishment. Those who were offensive to the crowd were in no small danger from the missiles by which they were assailed. The culprit was allowed to make speeches, defending himself and attacking his enemies. In England this punishment was first meted out for mean offenses, as using false weights, perjury and forgery, but it was extended to include libelers, and finally any who printed without a license. In 1816 this punishment was abolished in all cases except that of perjury. It was abolished totally in 1837, and in the United States in 1839. The exception was Delaware, which adhered to ancient methods of punishment until 1905.

PILLOW, Gideon Johnson, American soldier: b. Williamson County, Tenn., 8 June 1806; d. Lee County, Ark., 6 Oct. 1878. He was graduated at the University of Nashville, studied law, became prominent in the Democratic party of the State, and in 1844 as delegate to the National Convention did much to secure the nomination of Polk, his intimate friend, for the Presidency. In 1846 he was commissioned brigadier-general, immediately went to the front with his Tennessee volunteers, fought bravely at Vera Cruz, was severely wounded at Cerro Gordo, became second in command to General Scott, was again wounded at Churubusco, and after the war was accused by Scott of insubordination, but acquitted. His difference with Scott as to the Convention of Tacubaya seems to have been the origin of these charges. He opposed secession at first, acquiesced later, was made major-general of Tennessee troops, raised 35,000 men, and advanced to the Confederate government much money, which was never returned. Jefferson Davis disliked him and reduced his rank to brigadier. He fought under Leonidas Polk at Belmont 7 Nov. 1861, opposed the surrender of Fort Donelson February 1862, and thereafter did not figure in any battle save Murfreesboro, in which he had a courtesy command. He was ruined by the war, and tried heroically but vainly to recover his former financial position.

PILLOW, Fort. See FORT PILLOW.

PILLOW-LACE. See LACE.

PILLSBURY, pĭlz'bẽr-ĭ, **Harry N.,** American chess-player: b. Somerville, Mass., 5 Dec. 1872; d. Philadelphia, Pa., 17 June 1906. He won the world's championship at the Hastings International Chess Congress in England, in 1895, the first American to attain that honor since 1858. He tied with Tarrasch in 1898 in the international cable match at Vienna, divided second honors with Janowsky and Maroczy in 1899 and won first prize at the American tournament in Buffalo in 1901, and was an honored competitor in the leading international games. In 1897 he won the American championship by defeating J. W. Showalter. He made a record for blindfold play, conducting 22 games at one time, without sight of the boards or pieces, and winning most of the games. He was also a checker player of the first order.

PILLSBURY, John Sargent, American legislator: b. Sutton, N. H., 29 July 1828; d. Minneapolis, Minn., 18 Oct. 1901. He was engaged in various business ventures until 1872 when he became a member of the noted flour milling firm of Charles A. Pillsbury and Company. At the outbreak of the Civil War he organized three regiments for the Union army and later he assisted in the organization and equipment of other regiments for the suppression of an Indian uprising in Minnesota. In 1863 he was sent to the State senate and served almost continuously until elected governor in 1875, to which office he was twice re-elected. During his administration he prevented the repudiation of the Minnesota State Railway bonds and favored measures to benefit the agricultural portions of the State. He was a generous benefactor of educational institutions, hospitals, libraries, etc.

PILLSBURY, Parker, American reformer: b. Hamilton, Mass., 22 Sept. 1809; d. Concord, N. H., 7 July 1898. He was graduated in 1838 from Gilmanton Theological Seminary, studied also at Andover and became pastor of the Congregational Church at New London, N. H. Under the influence of William Lloyd Garrison's pleas, he joined the anti-slavery forces, withdrew from ministerial duties and became an anti-slavery lecturer in New England and the West. In 1854 he went to England and there lectured in the principal cities. He was one of the more violent of the abolition orators, but in his way effective. At different times he was editor of the *Herald of Freedom* at Concord, N. H., and of the *Anti-Slavery Standard* in New York. In his later years he was a preacher for various Western religious societies. He published his recollections of the anti-slavery struggle and its leaders as 'Acts of the Anti-slavery Apostles' (1883).

PILLSBURY, Walter Bowers, American psychologist: b. Burlington, Iowa, 21 July 1872. In 1888–90 he studied at Penn College, Oskaloosa, Iowa, and in 1892 was graduated at the University of Nebraska and in 1896 received the degree of D.Ph. at Cornell University. In 1895–97 he was assistant in psychology at Cornell; in 1897–1900 instructor, in 1900–05 assistant professor, in 1905–10 junior professor of philosophy and director of the psychological laboratory at the University of Michigan; then, full professor. Since 1929, he has been chairman of the Department of Psychology. His books include: 'Attention' (1908); 'Psychology of Reasoning' (1910); 'Essentials of Psychology' (1911, 1920); 'Fundamentals of Psychology' (1916, 1922); 'Psychology of Nationality' (1919); 'Education as the Psychologist Sees It' (1925); with C. L. Meader, 'Psychology of Language' (1928); 'History of Psychology' (1929). In 1917, he was chairman of the editorial committee on 'Studies in Psychology.'

PILOCARPINE, pī-lō-kär'pēn, an alkaloid, derived from jaborandi, a Brazilian shrub *(Pilocarpus pennatifolius)* of the order *Rutaceae.* Pilocarpine was isolated by Hardy and by Gerrard in 1875, synthesized by Preobrashenski, 1933. It is a colorless liquid of boiling point 260° C. at 5 mm. pressure, crystalline, it melts at 34° C. It is dextrorotatory, soluble in water or alcohol, nearly insoluble in ether. It forms numerous crystalline salts. The formula is $C_{11}H_{16}N_2O_2$, and an imidazole (glyoxaline) nucleus is present. Other alkaloids of *Pilocarpus* spp. are isopilocarpine, pilocarpidine, and pilosine. Pilocarpine causes increased activity of the secretory glands, vasomotor paralysis, and death by its effect on circulation and respiration. It is used as the nitrate, in glaucoma, as a diaphoretic, antidote to atropine, and in hair lotions. See also ALKALOIDS.

PILON, Germain, zhăr-măń pē-lōń, French sculptor: b. Paris, 1535; d. there, 4 Feb. 1590. He was a favorite court sculptor of Catherine de' Medici. Many of the works were destroyed in the Revolution. The earliest extant is a canopy for the tomb of Francis I at Saint Denis. In the chapel of Saint Eustache at Saint Denis is also the famous tomb of Henry II on which Pilon was occupied from 1564 to 1583. His 'Three Graces,' 'Saint Catherine du Val des Ecoliers,' erected by Cardinal Birague, the tomb of the cardinal himself, 'The Four Cardinal Virtues,' and others are now in the Louvre. A statue ordered by Catherine, 'Vièrge de Pitié,' is now in the church of Saint Paul and Saint Louis, Paris. Pilon, in the voluminous folds and tortuous lines in the draperies of his figures, marks the beginning of the decadence from the classic simplicity and strength of his immediate predecessor, Jean Goujon. Consult Gonse, L., 'La sculpture française.'

PILOS. See HATS AND HAT-MAKING.

PILOT, The; a Tale of the Sea, published in January 1824 (the earliest edition is actually dated 1823), was James Fenimore Cooper's fourth novel and his first sea tale. He had undertaken to surpass Scott's 'Pirate' (1821) in seamanship, and. a sailor by profession, not only succeeded in this but produced a book on almost every count better than its model. Indeed, Cooper may be said in 'The Pilot' to have created a new literary type, the tale of adventure on the sea, in which, although he was to have followers and rivals in many modern languages, he still keeps a high place for vigor and variety. Smollett had already discovered the racy humors of seamen, but he had seen little else in their calling; it remained for Cooper to capture for fiction the mystery and beauty, the shock and thrill, of the sea, which in his pages has much of the proud pomp of Byron's ocean. Experts say that Cooper's technical knowledge was sound; what is more important, he wrote a story about sailing vessels which convinces land-dwellers even in days of steam. Although based, with many realistic details, upon his own experience, 'The Pilot' has a large conventional element, chiefly in connection with its hero, John Paul Jones, who appears as always brooding upon a dark past and a darker fate. Yet he is not so morbid but that he can occasionally rouse himself to terrific activities in his raids along the English coast. Cooper credits him with a love affair, conventional in tone, and not important. Of the characters, only one possesses much interest or verisimilitude — Long Tom Coffin, of Nantucket, who takes his place worthily beside Harvey Birch and Natty Bumppo. If he seems hardly so vivid a patriot as the spy it is because he is first of all a sailor, and belongs to the open sea as Leather-Stocking belongs to the forest. Long Tom is as real as an oak; he is also as romantic as storms and tides.

CARL VAN DOREN.

PILOT CHART. See CHART.

PILOT-FISH, any of several fishes reputed to act as guides and sentinels to sharks, or resembling species so acting. The fish traditionally so called (*Naucrates auctor*) is a small mackerel-like member of the family *Carangidæ* (q.v.), which abounds in all warm seas, and was well known in the Mediterranean where the ancient fishermen observed its constant association with sharks, and its habit of following ships for many days together. They said it acted as a guide and protector of the sharks, leading them to prey and warning them of danger; and that when a mariner lost his way on the high seas it appeared and piloted him to port. The association with sharks and other large fishes and the following of ships are still observable, but the modern explanation is that the little fish gain food and some protection

from the big ones, and, therefore, seek to swim near them. They are excellent eating. Another nearly related fish (*Seriola zonata*), one of the amber-fishes, is called "shark's pilot" along the south Atlantic Coast of the United States; in the West Indies several chichlids are called black, or cow, or cockeye pilots; and in Lake Champlain this name is given to a whitefish (*Coregonus quadrilateralis*) called Menominee or round white-fish in the Northwestern lakes. Consult Goode, 'Fishery Industries, Sec. I' (1884); Day, 'Fauna of British India: Fishes' (1889).

PILOT AND HIS WIFE, The ('Lodsen og hans Hustru'), a novel by Jonas Lie, appeared in 1874. Lie is above all the story-teller of maritime life, and he has written many excellent novels dealing especially with sailors and fishermen and with scenes on the Norwegian coast. 'The Pilot and His Wife' portrays the life of the sailor both at home and abroad and gives us many a vivid picture of varied experiences out on the stormy deep as well as in distant ports. The work is noted for its vigor of description. With a background of ocean waves it is a story of married life, full of serious meaning. Salve Kristiansen loved a beautiful woman named Elisabeth and was evidently loved in return. But for a time Elisabeth was attracted to a young officer who wished to marry her. The old love for Salve prevailed, however, and Elisabeth spurned the officer, but Salve had already left his native land in desperation and was sailing toward foreign shores. When he finally, after some years, returned to his old home, he found that Elisabeth, after all, had been true to him. He married her, and it would seem that all was well, but such was not the case. The thought of Elisabeth's momentary hesitation did not leave Salve, and this unfortunate circumstance made life miserable for both. Ten years elapsed before husband and wife finally came to a clear understanding and a genuine appreciation of one another, and now at last they were enabled to lay the foundation for a happy life together. What the novel emphasizes is the need of implicit confidence and trust, if two persons united in wedlock are to live happily together. The author showed that there can be no joy in married life, if misgivings and doubts are allowed to flourish. If there is to be love, there must be no hypocrisy. Consult Henrik Jaeger, 'Illustreret norsk Literaturhistorie' (II: 768–825); Arne Garborg, 'Jonas Lie, en Udviklingshistorie.'

JOSEPH ALEXIS.

PILOT KNOB. (1) A mountain in southwestern Nevada; height, 10,758 feet. (2) A mountain of iron ore in Iron County, southeastern Missouri; height, 1,113 feet.

PILOT MOUNTAIN, in North Carolina, on the border of Stokes and Surrey Counties near Ararat River. See ARARAT.

PILOT PEAK. (1) A mountain in Utah; height, 10,720 feet; (2) A mountain in Plumas County, California; height, 7,508 feet.

PILOT and **PILOTAGE.** A pilot is a helmsman familiar with a particular water to which his official service is restricted by his license. At ports where water traffic is large the pilots maintain a pilot boat in which they go outside of the harbor to meet incoming vessels and guide them safely in. He must know thoroughly the bottom of the harbor, the local currents, and the tides. When he comes aboard of a vessel that has called him, he goes at once to the wheelhouse, and takes charge. In Great Britain and the United States every qualified pilot on his appointment receives a license for a particular district from the pilotage authority of that district. Masters or mates of any ship may, upon giving due notice, be examined and passed by the proper authorities, and receive pilotage certificates. In this case they must be renewed every year. Further, any master or mate of a ship may obtain, after examination, a certificate to the effect that he is authorized to pilot any ship or ships belonging to the same owner of and under a certain draft of water. Any qualified pilot who commits any fraud against the customs or excise, or is guilty of corrupt practices as to ships, cargoes, crews or passengers; who lends his license, acts as pilot while suspended or when drunk, causes unnecessary expense to enhance his own or someone else's gain; declines, without reasonable cause, to go off when signaled for or required; unnecessarily cuts or slips a cable; refuses to conduct a ship into port, except on reasonable ground of danger to the ship; or leaves the ship of which he is in charge, without the master's consent, before the service for which he was hired has been performed — renders himself liable to suspension or dismissal, as well as to a fine in addition to damages to the persons aggrieved. Pilotage fees depend on the draft of water of the ship piloted, and for vessels with a large draft of water are very much higher than for those with a small one. In Great Britain no owner or master of any ship is answerable to any person for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of such ship within any district where the employment of such pilot is compulsory; but the pilot must not be interfered with in the discharge of his duties. Other maritime countries have also passed laws to regulate the pilotage of vessels. In the United States each individual State makes its own regulations as authorized by act of Congress. The most important body of pilots in the United States are those under the pilot commissioners of New York. The master of a vessel with a pilot on board has still the management of the vessel, and sees that she is kept in the course the pilot directs. A master refusing to take a pilot often vitiates the insurance on the vessel.

PILOT-PLANT, the compass-plant (q.v.).

PILOT SNAKE, a common name for the copperhead (q.v.) in some localities, but properly the Mountain Blacksnake (*Coluber obsoletus*), preferably called the Pilot Blacksnake, to distinguish it from the common blacksnake.

PILOT WHALE, a caaing whale (q.v.).

PILOTY, pē-lō'tē, **Ferdinand,** German painter: b. Munich, 8 Oct. 1828; d. there, 21 Dec. 1895. After studying in the academy of his native city, he directed his artistic activity altogether under the influence of his brother Karl von Piloty, especially imitating him in technique and color. A number of his historical frescoes are to be seen in the National Museum at Munich and in the town-hall of Landsberg-on-Lech. He also painted in oils for the Maximilaneum at Munich the picture 'Elizabeth

of England reviewing her Troops in Sight of the Armada.' Of his other works, among the most notable are 'Sir Thomas More in Prison'; 'Raffael on a Sick Bed'; 'Count Eberhardt of Würtemberg by the Dead Body of His Son'; 'The Judgment of Solomon.' He designed many illustrations for Schiller's 'Glocke' and for the Shakespeare Gallery.

PILOTY, Karl von, German painter: b. Munich, 1 Oct. 1826; d. there, 21 July 1886. Beginning as a genre painter in his remarkable canvas 'The Nurse' (1853) he revealed for the first time a most brilliant technique which inaugurated a new style at Munich, and indeed throughout Germany. In 1854 he produced his first historical picture, 'The Institution of the Catholic League'; then followed 'Seni by the Corpse of Wallenstein' (1855); 'Nero Amid the Ruins of Rome' (1861); 'Godfrey de Bouillon with the Pilgrims at the Holy Sepulchre'; 'Assassination of Julius Cæsar' (1865); 'Columbus' (1866); 'Thusnelda in the Triumphal Procession of Germanicus' (1873), a replica of which is in the Metropolitan Museum of Art, New York; 'The Death of Alexander' (1877), unfinished. As the representative of a distinct school in German art he counts among his pupils and followers Makart, Max, Defregger, Lenbach, J. Brandt, etc. Consult Rosenberg, 'Die Münchener Malerschule' (1887).

PILPAY, pĭl'pī, or **PILPAI.** See Bidpai.

PILS, pēlz, **Isidore Alexandre Auguste,** French painter: b. Paris, 1815; d. Douarnenez, Brittany, 3 Sept. 1875. His first success, after trying religious subjects, was in 1848 with 'Rouget de l'Isle chantant pour la première fois la Marseillaise' (Louvre). His greatest successes were with military scenes such as 'Débarquement en Crimée' and 'Bataille de l'Alma,' and water-color studies of soldiers during the siege of Paris. He was professor at the École des Beaux Arts and Membre de l'Institut.

PILSBRY, pĭlz'brĭ, **Henry Augustus,** American conchologist: b. Iowa City, Iowa, 8 Dec. 1862. He was educated at the State University of Iowa, from which he received the degree of D.Sc. in 1899. He has made a lifelong study of mollusks and has been special curator of the department of mollusks at the Philadelphia Academy of Natural Science since 1888. He has published 'The Manual of Conchology' (37 vols. 1888–1927); 'Marine Mollusks of Japan' (1895); 'Guide to the Study of Helices' (1907); 'Barnacles of the United States' (1907); 'Mollusks of the Belgian Congo' (1927); also about 250 articles on conchology, geology, and zoölogy in journals of the scientific societies—American and foreign.

PILSEN (Plzen), since 1939 an important city of the Protectorate of Bohemia, at the confluence of the Radbusa with the Mies (Beraun), 53 miles southwest of Prague. It consists of the town proper and extensive suburbs; is a well-built, handsome place; has a splendid Gothic church of the 13th century; a townhouse, Franciscan monastery, a German and Czech theatre, German and Czech gymnasia, barracks; and important and varied industries, embracing machinery and metal wares, porcelain, glass, liquers, refined spirits, etc., and large breweries which produce a famous variety of beer. Coal, iron and alum mines are in the vicinity, and there is a considerable trade. Pilsen possessed a printing press as early as 1468. It was once a fortified town, and was several times besieged during the Hussite wars. In 1618 it was stormed by Mansfield, and in the Thirty Years' War was for a time the headquarters of Wallenstein. The people are mainly Czechs. It has grown fast in modern times, from 38,883 population in 1880 to 88,416 in 1926.

PILSUDSKI, Josef, marshal of Poland: b. Zulow, near Vilna, Poland, 1867, of Polish-Lithuanian stock; entered University of Cracow in 1885, where he became connected with the Socialist movement. Though he refused to participate in a plot to attempt the life of the Tsar Alexander III, he was nevertheless banished to Siberia in 1887. A general amnesty freed him five years later, and he returned to Vilna, where he engaged in forming the Polish Socialist Party. His activities caused his arrest in 1896, and imprisonment, first in Warsaw and then in Saint Petersburg (now Leningrad). From the latter he escaped, but was arrested again in 1900, and again escaped, this time going to London. The Socialist movement had become popular by 1904 and Pilsudski took charge of its military organization. By 1907, Russia, using drastic measures, had quelled insurrection, but Pilsudski continued his work of organization which became world-wide. At the outbreak of the World War his efforts were turned against Russia. His successes and increasing strength found disfavor with Austria and Germany. In 1917 the Polish Legionnaires were ordered to take the oath of allegiance to these powers, but refused. General Pilsudski was imprisoned at Magdeburg. The Socialist revolution in Germany brought his release, and he immediately set himself to the task of establishing a Polish government, organizing an army and serving as temporary head of the state. He successfully conducted warfare against the Ukraine and Czechoslovakia in 1919 and eventually drove back the Bolsheviks (1920). He retired after the election of the first President in 1922; but the *coup d'état* of May 1926 restored him as virtual dictator, 15 May. He demanded a strong government to meet Poland's pressing problems. He refused the presidency but in October 1926 became Premier and Minister of Military Affairs, holding the latter position until his death, 12 May 1935.

PILTDOWN MAN or **DAWN MAN.** See Anthropology; Man, Prehistoric Races of.

PIM, Bedford Clapperton Trevelyan, English naval officer: b. Biddeford, England, 12 June 1826; d. London, England, 1 Oct. 1886. He was educated at the Royal Naval School and entered the English navy in 1842; took part in the Franklin search expedition in 1852; commanded a gunboat on the Baltic during the Crimean War; served in China in 1857, and was promoted commander in 1858. In 1859 he served in Central America and surveyed the Nicaragua Canal route. He was retired from active service in 1861, but received rank as rear-admiral in 1885. He was admitted to the bar in 1873 and was a member of Parliament, 1874–80. He wrote 'The Gate of the Pacific' (1863); 'Jottings on the Roadside in Panama, Nicaragua and Mosquito' (1869), etc.

PIMAN (pēmạn) **STOCK,** an American family or group residing in Mexico and Ari-

zona. The stock includes among other tribes the Papagos, Pimos, Gatschets, Tarumaris, Yaquis and Huichols. The Piman family is a southern extension of the Shoshone (q.v.) family. They number about 90,000. Consult Russell, F., 'The Pima' (in 26th Annual Report, Bureau of American Ethnology, Washington 1908).

PIMENTA, or **PIMENTO.** See ALLSPICE.

PIMLICO. See FRIAR-BIRD.

PIMO, or PIMA INDIANS, an American tribe of the Piman family, living in Arizona, in the valley of the Gila. They are neighbors of the Maricopas, whom they resemble so much in person and manners that they are not easily distinguished from them. Their number is about 4,000. The men have slender forms, but the women, who do most of the hard labor, are well made. Agriculture is their principal occupation. They are the most civilized of any of the North American Indians; they manufacture cotton fabrics, pottery and other useful articles with considerable skill, and enjoy a reputation for simplicity of character, peacefulness and honesty. The only weapon used by the tribe is the bow and arrow. They possess horses and cattle, but very few mules. About two-thirds of the Pimos live on government reservations. See PIMAN STOCK.

PIMPERNEL, a flowering plant of the primrose family and genus *Anagallis,* with a wheel-shaped corolla. The scarlet or field pimpernel (*A. arvensis*) is wild in Europe, and both cultivated and run-wild all over the world. The small flowers are usually scarlet with a purple spot in the centre, but in one variety blue. This species is commonly known in England as the "poor man's weather-glass," from the fact that its flowers do not open in rainy weather. The bog pimpernel (*A. tenella*) is an extremely delicate and beautiful plant, which naturally grows in the drier parts of marshes; its flowers are red, and it is distinguished from the field pimpernel by the fact that its corolla considerably exceeds the calyx. The blue and lilac varieties of *A. collina,* a native of South Africa, have been introduced into gardens generally, where they have a fine effect. A closely allied plant (*Centunculus minimus*) is called false pimpernel or chaff-weed.

The *Pimpinellas,* especially *P. integerrima,* have also been called (erroneously) by the name 'pimpernel.' They belong to the *Apiaceæ. P. integerrima,* in some localities is familiarly known as the 'wood pimpernel.'

PIMPLES, eruptions of the skin, of which several varieties are distinguished by special names, but various causes may transform one of these into another. The typical pimple is a slight swelling with an inflamed base. The papule is a solid elevation, apparently containing no fluid, and either of the natural skin-color, or bluish, blackish, etc. The vesicle is an elevation of about the same size, containing a clear or milky fluid; by alteration of its contents to yellow pus it becomes a pustule. A bleb or bulla is a larger vesicle or pustule, and may be as large as a hen's egg. A large papule is called a tubercle, and wheal is the term applied when the raised skin is of greater extent than elevation.

PIN, a small piece of brass or steel wire, sharp at one end and furnished with a head at the other, used chiefly for the toilet for temporarily securing portions of the dress, and generally by seamstresses and tailors for fastening their work together. The need of little utensils of this sort has been met from ancient times by various devices. The original pin must have been slit from the shaft of a bird's feather, as the root word, Latin *pinna,* means feather. In the Egyptian tombs they are found much more elaborate and costly than the pins of the present time. They vary in length up to seven or eight inches, and are furnished sometimes with large gold heads, and sometimes with a band of gold around the upper end, those of the latter kind having probably been used for securing the hair. The ancient Mexicans found in the thorns of the agave convenient substitutes for metallic pins; and even the English, up to the middle of the 16th century, made use of rude skewers of wood, though they also made others of gold, silver and brass to serve as pins. To that time they had depended upon the manufacturers on the Continent for their supplies of the better sorts of pins, and this importation appears to have been established previous to 1483, when it was interrupted by a prohibitory statute. In 1543 an act of Parliament provided "that no person shall put to sale any pins but only such as be double-headed and have the head soldered fast to the shank of the pin, well smoothed, the shank well shaven, the point well and roundly filed, canted and sharpened." Within three years from this time the manufacture was so much improved that the statute was of no importance. In Gloucester the business of pin making was introduced in 1626, and soon proved so prosperous that it gave employment to 1,500 persons. It was established in London in 1636, and afterward in Birmingham, which became the chief seat in England of this and other manufacturing operations of similar character.

In the United States pins were first made in Rhode Island during the Revolution by Jeremiah Wilkinson, the heads being made by twisting fine wires firmly at one end. Samuel Slocum at about the same time commenced in Providence in the same line. In 1824 a machine for making solid-headed pins was invented by Lemuel W. Wright, of New Hampshire, which was soon after introduced into England, patents also being granted there. It was, however, crude compared with those of later construction, and did not complete all the operations of pin making. In 1831 the first machine for making perfect solid-headed pins like those now in use was invented by John Ireland Howe, a physician of Bellevue Hospital, New York City, and in the next year a company was started in that city. Six years later the business was removed to Derby, Conn., where it is still carried on. In 1835 another company was formed by Dr. Howe, which continued its operations under his charge till 1865, many improvements being made. Samuel Slocum, an ingenious Connecticut man, invented a pin-sticking machine, which was used in Howe's factory in 1841, and was improved in 1843, he and Slocum becoming joint owners of the two patents.

The manufacture of pins has become such an industry in the United States that the mills of

this country practically supply the world with this article. In 1900 the 75,000,000 people in the United States used 60,000,000 gross of common pins, which is equal to 8,600,000,000 pins, or an average of about 113 pins for every man, woman and child in the country. This is the highest average reached anywhere in the use of pins. In 1890 we used only about 72 pins each. Assuming that the present consumption is 125 per individual, the 118,628,000 people of the United States today use about 14,828,500,000 pins. The census lumps together the makers of pins, needles, hooks and eyes, so exact statistics are no longer available. It appears, however, that more than half the pins are made in the State of Connecticut, where there are eight factories, employing 3,000 people.

The common pin is of brass with a tinned surface. Pins now are turned out by automatic machines in such quantities that the cost of manufacture is slightly greater than the value of the brass wire from which they are made. A single machine does the work. Coils of wire, hung upon reels, are passed into machines which cut them into proper lengths, and they drop off into a receptacle and arrange themselves in the line of a slot formed by two bars. When they reach the lower end of the bars they are seized and pressed between two dies, which form the heads, and pass along into the grip of another steel device, which points them by pressure. They are then dropped into a solution of sour beer, whirling as they go, to be cleaned, and then into a hot solution of tin, which is also kept revolving. They here receive their bright coat of metal, and are pushed along, killing time, until they have had an opportunity to harden, when they are dropped into a revolving barrel of bran and sawdust, which cools and polishes them at the same time. Because of the oscillation of the bran they work gradually down to the bottom of the barrel, which is a metallic plate cut into slits just big enough for the body of the pins, but not big enough for the head to pass through. Thus they are straightened out into rows again, and, like well drilled soldiers, pass along toward the edge of the bottom, and slide down an inclined plane, still hanging by their heads, until they reach strips of paper, to which they are introduced by a curious jerk of the machine. The first they know they are all placed in rows, wrapped up and on their way to the big department stores, where they are sold at a small price. A machine is expected to throw out several thousand gross an hour. Hairpins and safety pins and other kinds of pins are all manufactured by somewhat similar special machinery.

The word pin is applied in mechanics to any relatively small straight piece of metal that serves to join parts. The crank-pin of a great steamship's mainshaft may weigh a ton, whereas a pin in a watch-plate may be difficult to discern. A wooden pin is now more commonly called a peg. Both needles and hairpins are manufactured to a greater extent in Europe than plain pins. Safety pins, however, are decidedly American, and of these we make on an average 1,000,000 gross a year.

PIN-MONEY, the money which a husband hands a wife for minor personal expenses; in law, an annual sum of money, sometimes provided for in a marriage settlement, to be paid by the husband to the wife for her separate use, and to be applied in the purchase of apparel, ornaments for her person or for private expenditure. See HUSBAND AND WIFE.

PINA (pē'nyä) **CLOTH,** an extremely soft and delicate fabric, the manufacture of which is peculiar to the Philippines. It is made from the unspun fibres of the leaves of the cultivated pineapple plant, and the finer qualities are always made in small pieces, since only single fibres are used for them. For the coarser qualities several fibres are often joined together, so as to make warp threads of considerable length. Its color is almost white, but has a slight tinge of yellow in it. Its chief use is for making ladies' pocket handkerchiefs, which are frequently adorned with exquisite embroidery.

PINAFORE, H. M. S., a comic opera in two acts, libretto by W. S. Gilbert, music by Sir Arthur Sullivan; first produced at the Opéra Comique in London, 25 May 1878. First authorized appearance in America, November 1879, at the Boston Museum. Replete with those nonsensical whimsicalities which have given the word "Gilbertian" to the English language, this opera with its dainty music became an immediate success. The captain of H. M. S. *Pinafore* wants his daughter (Josephine) to marry Sir Joseph Porter, First Lord of the Admiralty, but she is in love with Ralph, a sailor. They agree to elope, but their plan is betrayed by Dick Deadeye, the villain. A bumboat woman, Little Buttercup (in love with the captain), informs the First Lord that the captain and Ralph had accidentally been exchanged as infants. To rectify this error, the First Lord reduces the captain to ordinary sailor and makes Ralph captain. Both Josephine and Little Buttercup wed the lovers of their choice under this grotesque arrangement and with the blessing of the First Lord.

PINAKOTHEK, pĭn'ą-kō-thĕk (Ger. pē-nä-kō-tāk') (Greek, "collection of pictures"), anciently, a chamber in which votive pictures of the gods were hung in Greece. Such a chamber was situated in the left wing of the propylæum or gate of the acropolis at Athens. In other states (Samos, Ephesus, etc.) special buildings were raised for the storing of votive tablets. Among the Romans the entrance to the atrium of their houses was adorned with statues, pictures and other objects of art. In Munich at the present day the term is applied to a public art gallery, and there is in that city an old and a new pinakothek.

PINALOBO, pē-nä-lō'bō, a mountain of the Cordillera de Cabusilan, Philippines, in the northwestern part of the province of Pampanga, near the intersection of the boundary of Tárlac and Pampanga with Zambales. It is 6,040 feet in height, and the highest of a series of peaks which ends in the south with the Mariveles summits and forms a landmark for Súbic Bay and for vessels approaching Manila Bay from Hongkong and northern China.

PINAR DEL RIO, pē-när' dĕl rē'ō, Cuba, the most western province of the island, bounded on the east by Habana province, area, 5,206 square miles. The Cordillera de los

Organos traverses the centre of the province from east to west, and from this range the land slopes gradually to the coasts, which are generally low and marshy. The southern slope is the most fertile, and forms the famous Vuelta Abajo, where the finest quality of tobacco in the world is grown. Coffee, sugar cane and pineapples are important crops, and cattle-raising flourishes. The heavily-wooded mountains contain much pine and lumbering and charcoal-burning are carried on. The Matahambre, Cuba's largest copper mine, yields about 25,000,000 pounds annually, and there are immense asphalt deposits at Mariel and Bahia Hondo. Pop. (1933) 347,664. See CUBA.

PINAR DEL RIO, Cuba, city, capital of the province of Pinar del Rio, 95 miles southwest of Havana. It was founded in 1776. It is connected with Havana by rail and with La Coloma by highway, and being situated on the southern slope of the mountains is the commercial centre of the tobacco-growing district, Vuelta Abajo. It has grown very rapidly in recent years. Pop. (1934) 63,213.

PINASTER. See PINE.

PINCHBACK, Pinckney Benton Stewart, American lawyer and politician: b. Macon, Ga., 10 May 1837. He was of negro stock, studied in the public schools of Cincinnati, became a river boatman, and in 1862 enlisted in the Union army. In 1867 he was made inspector of customs at New Orleans. He took a prominent part in politics as a Republican leader; was a delegate to the Reconstruction Convention of the State in 1867; was State senator, 1868–71, lieutenant-governor, 1871–72, and acting governor during Warmoth's impeachment December–January 1872–73. He was elected to the United States Senate in 1873, but was never seated though he received regular pay and mileage; in 1882 was named surveyor of customs of New Orleans; and in 1886 was admitted to the bar, but a few years later retired. Deceased.

PINCHBECK, an alloy formerly in use, four parts copper and one part zinc, with occasional traces of tin, used in the manufacture of cheap jewelry. It has something the appearance of gold, but became notable as a synonym for cheapness. It was named from its discoverer, CHRISTOPHER PINCHBECK, a London jeweler: b. about 1670; d. 18 Nov. 1732. He made clocks, watches, astronomical instruments and various automata, especially musical, which he exhibited at fairs.

PINCHE, a sort of marmoset (q.v.).

PINCHOT, pĭn'shō, **Amos Richard Eno,** American lawyer and publicist: b. Paris, France, 6 Dec. 1873. In 1897 he was graduated at Yale University and subsequently studied law at Columbia University and the New York Law School. Mr. Pinchot served in Porto Rico during the Spanish-American War and in 1900–01 was deputy assistant district attorney of New York County (borough of Manhattan). Mr. Pinchot became an active worker along sociological lines and wrote much on industrial, charity and social organization generally. He supported Theodore Roosevelt in 1912 in organizing the Progressive party, but left the party two years later after a controversy with George W. Perkins, of the Harvester Trust. He is a trustee of the People's Institute and one of the founders of the Pinchot School of Forestry of Yale University.

PINCHOT, Gifford, American public official and forestry expert: b. Simsbury, Conn., 11 Aug. 1865. He was graduated from Yale University in 1889, and thereafter studied forestry in France, Germany, Switzerland and Austria. In January 1892 he began the first systematic forest work in the United States at Biltmore, N. C. This work attracted much attention and in 1893 he established himself in New York City as a consulting forester. He became a member of the National Forest Commission in 1896. From 1898 until 1910 he was forester and chief of the Division of Forestry (afterward the Bureau of Forestry and now the Forest Service of the United States Department of Agriculture). In 1909 Mr. Pinchot engaged in a controversy with Secretary of the Interior Richard A. Ballinger over the latter's policies. The following year the President dismissed Mr. Pinchot for insubordination. Mr. Pinchot is one of the founders of the Pinchot School of Forestry at Yale University, and from 1903–36 was professor of forestry in that institution. He was Pennsylvania's Commissioner of Forestry 1920–1923. In 1912 Mr. Pinchot supported the Progressive Party, led by the late Col. Theodore Roosevelt, and in 1914 was that party's candidate for United States senator from Pennsylvania, but was defeated. In 1922 Mr. Pinchot received the Republican nomination for governor of Pennsylvania defeating the organization's candidate, Attorney-General George E. Alter in the primaries. In the November election Mr. Pinchot defeated his Democratic opponent by a vote of 831,696 to 581,625. In August 1923, Governor Pinchot, as Federal mediator, aided in settling the strike of the anthracite miners, who received a wage increase of 10 per cent. In the 1930 elections Mr. Pinchot was again elected Governor of Pennsylvania for a four-year term (1931–35). Mr. Pinchot's publications include: (with H. S. Graves) 'The White Pine' (1896); 'The Adirondack Spruce' (1898); 'Primer of Forestry' (1899); 'The Fight for Conservation' (1909); with C. O. Gill, 'The Country Church' (1913) and 'Six Thousand Country Churches' (1919).

PINCKNEY, pĭnk'nĭ, **Charles,** American statesman: b. Charleston, S. C., 1758; d. there, 29 Oct. 1824. He was educated for the bar, was elected to the provincial legislature, was held prisoner from the capture of Charleston until the end of the Revolution, then resumed practice, and in 1785 was chosen to the provincial congress. In 1787 he was a delegate to the United States Constitutional Convention, in 1789 was elected governor of South Carolina and in 1791 and 1796 was re-elected. He was elected to the United States Senate as a Republican in 1798, in 1802–03 was Minister to Spain and in 1806 was made for the fourth time governor of South Carolina. In 1819–21 he was in Congress, where he opposed the Missouri Compromise. He wrote well on political topics and his addresses to the people under the pseudonym «Republican» (1800) were of assistance in Jefferson's election to the Presidency.

PINCKNEY, pĭnk'nĭ, **Charles Cotesworth,** American soldier and statesman: b. Charleston,

S. C., 25 Feb. 1746; d. there, 16 Aug. 1825. He was educated at Oxford; read law in the Middle Temple, London; studied military affairs in the Royal Academy at Caen, France, and in 1769 began the practice of law in Charleston. He was a member of the first provincial congress of South Carolina (1775), and during the Revolution served with distinction in the Continental army. During the second attack on Charleston he at first commanded Fort Moultrie, but after the entrance of the enemy's fleet into the harbor withdrew to the city, and was taken prisoner at the capitulation in May 1780. He was held in severe confinement for two years, exchanged in 1782 and made a brigadier in 1783. In 1787 he was a member of the United States Constitutional Convention, and took an active part in the busy debates connected with the framing of the instrument. He favored the slave trade, urged a landed-property qualification for the executive, judiciary and the legislative department; and demanded that blacks be counted equally with whites in the estimate for representation in the national legislature. It was he who secured the insertion in the Constitution of the clause that "no religious test shall ever be required as a qualification to any office or public trust under the authority of the United States." Under the Constitution he was a zealous Federalist. He was a member of the State Constitutional Convention of South Carolina in 1790 and in 1796 became United States Minister Plenipotentiary to France. Ordered by the Directory to quit France within 30 days, he retired to Amsterdam, and on his arrival in America was made (1797) major-general of United States troops by President Washington. It was during the French mission that Pinckney, in response to Talleyrand's insinuation that recognition might be obtained by money, for lack of which war might follow, is said to have replied: "Millions for defense, but not a cent for tribute!" In 1800 he was Federalist candidate for the Vice-Presidency, and in 1804 and 1808 for the Presidency.

PINCKNEY, Thomas, American diplomat and soldier: b. Charleston, S. C., 23 Oct. 1750; d. there, 2 Nov. 1828. He was educated in England with his brother, Charles Cotesworth, was called to the English bar in 1770, returned to Charleston in 1772 and in 1775 entered the Constitutional Congress as a zealous Federalist. He acted as aide to Lincoln, D'Estaing and Gates, distinguished himself in the engagements at Stone Ferry and Savannah in 1779, and at Camden in 1780 was wounded and taken prisoner, not regaining his liberty until the end of the war. In 1787–89 he was governor of South Carolina, Minister to England in 1792–94 and in 1794–96 was engaged in a special mission to Spain, with whom he secured in 1795 a treaty which granted to the United States free navigation of the Mississippi for three years. He was a member of Congress in 1799–1801 and in the War of 1812 was major-general in command of the 6th military district where he utterly routed the Creek Indians at Horse Shoe Bend. He spent the remaining years of his life in retirement. Consult his 'Life' by C. C. Pinckney (Boston 1895).

PINCKNEYVILLE, pĭnk'nĭ-vĭl, Ill., city and county-seat of Perry County, on the Illinois Central and the Wabash, Chester and Western railroads, 60 miles southeast of Saint Louis. It has extensive lumber, flouring and coal-mining interests. In 1915 the commission form of government was adopted. The city owns its water-supply system. Pop. (1920) 2,649; (1930) 3,046.

PINDAR (Gr. Πίνδαρος), Greek lyric poet: b. Cynoscephalæ, near Thebes, 522 B.C.; d. Argos, probably 443 B.C. For the development of his poetical talent he was sent to Athens, where he became the pupil of Lasus of Hermione, the Athenian school of dithyrambic poetry. On his return to Thebes he was especially indebted for the further cultivation of his poetic gifts to Corinna, a distinguished poetess. He was held in great honor by many princes of Greek states, for whom he composed choral songs. Alexander, king of Macedonia, was one of his most ardent patrons. He regularly attended the contests at Olympia, Delphi and elsewhere, and frequently attended the victors home to direct triumphal ceremonies. In 472 he visited Sicily, the courts of King Thero of Agrigentum and King Hiero I of Syracuse. Æschylus made a journey to the island at about the same time; and rival descriptions of the eruption of Ætna appear in the 'Odes' and in Æschylus' 'Prometheus.' Pindar practised all kinds of lyric poetry and excelled equally in all. His works embraced hymns to the gods, pæans, dithyrambs, dancing and drinking songs, dirges, panegyrics on princes and hymns in honor of the victors of the games, but the only poems of his, with one exception, which have come down to us entire belong to the last class, the 'Epinikia.' The one exception referred to is the ode which appears in editions of Pindar as the 11th Nemean, and was intended to celebrate the installation of Aristagoras as prytanis at Tenedos. Forty-five of the epinikion odes of Pindar are still extant (including the one just mentioned). Of all, undoubtedly the fourth Pythian, in honor of the victory in the chariot race of Arcesilas, king of Cyrene, is the finest. His poems celebrated not alone the conquerors and their fellow-citizens, but all assembled Greece, and thus were soon spread wherever the Greek language was spoken. To understand Pindar it is necessary to be intimately acquainted with Greek antiquities. In the judgment of the best critics his poems belong to the most beautiful remains of ancient literature. They are marked by profundity of thought, elevation of diction and majesty of rhythm. Fragments of his other works have also been preserved.

PINDAR, Odes of. Few names were so venerated among the ancient Greeks as the great Theban poet, Pindar. As Homer was their "epic poet" and Sophocles their "tragic poet," so Pindar was their "lyric poet." His chair was preserved at Delphi, and at the periodic theogenia or sacred festival it was the custom of the priest of Apollo to call out, "Let Pindar the poet go into the banquet of the god." At the destruction of Thebes, Alexander the Great

> "bade spare
> The house of Pindarus, when temple and tower
> Went to the ground."

Pindar belonged to the school of Dorian choral poets. His fragments represent nearly

every kind of lyric poem. These were composed as if to be sung on the spot in immediate celebration of the victory; but in the nature of the case this could seldom be, and the ode was generally composed later, to be sung at a commemoration festival at the home-town of the victor. Like all choral lyrics, the epinikion was essentially narrative; it is, however, not the story of the contest that Pindar gives, but some myth of the family or race which at once tells an appropriate tale and points a moral. This digression was the heart of the ode; but its connection with the hero's victory is not always easy to see. The ode, once composed — in strophe and antistrophe, or both these with epode — a band of youths was carefully selected to render it with song and rhythmic movement. The ancient Hellene felt, as no mortal can ever feel again, that "there is no greater glory for a man while yet he lives than that he achieves with hand and foot"; and no pains or expense was spared by the victor's fellow-townsmen to bring out Pindar's ode with proper splendor.

It is not possible for moderns to appreciate the full excellence of the Pindaric ode. It was not merely a spectacle in honor of a man; the celebration was an act of divine worship and the poet was filled with religious fervor. The odes were meant to be sung, not read, and the music is lost; besides the scenic accessories are all gone. No great poetry can be really translated, least of all Pindar. Perhaps there is no great poet in all the world's literature of whom a less adequate conception can be obtained through translations. As Jebb eloquently says, "The glory of his song has passed forever from the world with the sound of the rolling harmonies on which it once was borne, with the splendor of rushing chariots and athletic forms around which it threw its radiance, with the white-pillared cities by the Ægean or Sicilian Sea in which it wrought its spell, with the beliefs or joys which it ennobled; but those who love his poetry and who strive to enter into its high places can still know that they breathe a pure and bracing air and can still feel vibrating through a clear calm sky the strong pulse of the eagle's wings as he soars with steady eyes against the sun." The price of knowing Pindar is high, but those who pay it have no regrets. For the great majority, Pindar is a lost art, but the few know that it is a very great art; and for the sake of our standards in literature it is devoutly to be hoped that such a saving remnant, however small, may always be found. Pindar's standard was so high and his achievements so sure that the modern world cannot afford to lose the tradition of his high excellence. While many especially great qualities might be mentioned, there is space here to emphasize only one — his style. Matthew Arnold coined the word "Pindarism" to express it, saying, "Pindar is a poet on whom, above all other poets, the power of style seems to have exercised an inspiring and intoxicating effect." The chief characteristic of that style was splendor. "To Pindar's soul splendor was as elemental as harmony to Milton's." This quality is best exhibited in some passages from the Epinikia, but these cannot be translated. There is a tenderer beauty perhaps in this picture from the second *Olympian* of the happy dead in the Islands of the Blest:

"Where the soft Ocean breezes float for ever
Around the Islands of the Blest.
There golden bloom to bloom succeeds,
Through springs that never tire.
They fill with light the ground below,
Athwart the shining trees they glow;
Their growth the very water feels,
Hid under flowers of fire."

A similar beautiful picture is this fragment of a threnos:

"For them the night all through,
In that broad realm below,
The splendor of the sun spreads endless light;
'Mid rosy meadows bright,
Their city of the tombs with incense-trees.
And golden chalices
Of flowers, and fruitage fair,
Scenting the breezy air,
Is laden. There with horses and with play,
With games and lyres, they while the hours away.
On every side around
Pure happiness is found,
With all the blooming beauty of the world;
There fragrant smoke, upcurled
From altars where the blazing fire is dense
With perfumed frankincense,
Burned unto gods in heaven,
Through all the land is driven,
Making its pleasant places odorous
With scented gales and sweet airs amorous."

For a discussion of English Pindaric odes, consult Edmund Gosse's Introduction to his 'English Odes.' Gray's two Pindaric odes, the 'Progress of Poesy' and 'The Bard,' are perhaps the most famous in our language; Akenside's series of odes are regarded as coming nearer to the Greek model than any other imitations, but they lack inspiration. Perhaps the best English editions of Pindar are the complete edition of C. A. M. Fennell (1893–99); the 'Olympian and Pythian Odes,' by B. L. Gildersleeve (1885); the 'Nemean and Isthmian Odes,' by J. B. Bury (1890–92). The best translation is the prose rendering by E. Myers (revised 1883). Consult Jebb, 'Lectures on Greek Poetry' (1893); Fraccaroli, 'Le odi di Pindaro' (1894); also Morice, F. A., 'Pindar,' in *Ancient Classics for English Readers.*

CHAS. FORSTER SMITH.

PINDEMONTE, pēn-dā-mōn'tā, CAVALIERE **Ippolito,** Italian poet: b. Verona, 13 Nov. 1753; d. there, 18 Nov. 1828. He was of a rich and cultured family, and early showed signs of poetical taste and ability. He traveled in England, Germany and France, and, like the great English poets of the epoch, greeted with joy the French Revolution, publishing 'La Francia' in 1789, but was soon disillusioned by its excesses and especially by the sufferings of Italy, which followed it. His principal poems were 'Poesie Campestré' (1788), filled with charming descriptions of British scenery; 'Dodici Sermoni Poetici' (1819), in a Horatian manner; and 'Arminio' (1804), a tragedy. These are classic in manner, graceful and tinged with melancholy.

PINDEMONTE, MARCHESE **Giovanni,** Italian dramatist, brother of Ippolito Pindemonte (q.v.): b. Verona, Dec. 1751; d. there, 12 Jan. 1812. His early years were full of political ups-and-downs, now in Italy in high office and again living in exile in France. In 1802 he became a member of the Italian Parliament. He was a brilliant improvisateur, a

translator of note, like his brother, and the author of 10 tragedies, of which the best are 'I Baccanali' and 'Ginevra di Scozia.'

PINDHAREES, pĭn-dăr'ēz, **PINDARees,** or **PINDARIS,** the name given to the hordes of mounted robbers in central India who for several years (after 1812) infested the possessions of the East India Company. These freebooters had existed since 1761, but made themselves particularly formidable in the beginning of the following century. They were descended mostly from the caste of Mohammedan warriors, which formerly received high pay from the Indian princes. But the British East India Company disarmed many of the tributary native princes and maintained under the command of the British residents at the Indian courts large bodies of mercenary troops, which the mediatized nabobs were obliged to pay. The number of the Pindarees was thus increased, and they were secretly excited by the Indian tributaries to attack the company. In the last year of their excesses, 1816, they sacked over 300 villages. In 1817 the British governor-general, the Marquis of Hastings, determined on the destruction of these robbers, whose force was estimated at 40,000 horse and 160,000 infantry. Attacked on all sides, they were conquered and dispersed.

PINDUS, *in ancient geography,* the main range of northern Greece between Thessaly and Epirus, running from the northwest to the southeast, and the source in its northern part of the principal rivers of Greece, the Achelous, Haliacmon and Peneius. The range includes practically all the mountains of Albania. It is well watered and heavily wooded and contains large tracts of original forest. Anciently its inhabitants were the half barbarian Athamanes and Dolopes, and the range, like Parnassus and Helicon, was sacred to the Muses and to Apollo. The inmost recesses of the mountains were the fortress and hiding place of determined brigands in the days of Ali Pasha. Its present inhabitants are peaceable shepherds and farmers, both Greeks and Albanians. The highest peaks reach 8,000 feet in height. Geologically the formation is calcareous.

PINE, a genus (*Pinus*) of trees and a few shrubs of the order *Coniferæ.* The species, of which about 70 well-marked ones have been described, are natives of the Northern hemisphere and more than half are indigenous to North America. Their distribution is from the Arctic zone to near the Equator, where, however, they are found only near the snow-line on the mountains. They are characterized by resiniferous wood, foliage, etc.; usually tall trunks; spreading branches which form a pyramidal or round top; needle-like leaves arranged in clusters of two, three or five, sometimes solitary; yellow or purple staminate flowers, greenish or purplish pistillate ones, the latter developing into usually cylindrical brown cones, which vary in size from less than an inch to 18 inches long and reach maturity generally when two years old; some not until three or more years of age.

Economically the pines are more important than any other timber trees used by man; the nearest rival being the oaks. The main reasons for this eminence are the wide extant of their distribution, the enormous area occupied, their adaptability to human needs and their occurrence largely upon poor land unfit for agricultural purposes. Not only for fuel and for timber are they noted; certain species yield pitch, tar and turpentine, used extensively for naval supplies; the leaves of several are made into "pine wool" and also furnish essential oils; the seeds of other species are used as food and for flavoring; and many are serviceable as windbreaks and shelter-belts or for ornamental planting. They thrive on a wide variety of soils, from beach-sand to alluvial river bottoms or rocky mountain-sides; and usually are found in large numbers together, often to the exclusion of other trees.

Pines are readily propagated by seeds, which in some species may require more than one year to germinate, unless planted as soon as gathered. They do best in a moderately moist soil enriched only to a slight depth so as to encourage the formation to surface roots rather than tap roots. While little they generally need partial shade and care in watering, both extremes of wetness and of dryness being avoided. When two years old or younger they are transplanted to increase the stockiness of the roots and render the trees better able to stand transplanting to final quarters. In general, the species do best in dry, upland soils, sandy rather than clayey, poor rather than rich, though soils of moderate texture and richness suit them well. When removed from the nursery rows the roots should be puddled in loamy mud to prevent the drying of the rootlets. Generally, best results are obtained in transplanting in the spring, before growth starts and selecting youngest specimens or such as have been transplanted in the nursery several times.

A very large number of insects feed upon the pine, nearly 300 being recorded in Europe and 200 in America, although the actual number in this country is probably twice as many. Of these probably the most troublesome are the borers, of which a very large number are known, among which the following may be mentioned: Wood-engraver bark-beetle (*Xyleborus cælatus*), which attacks the Georgia and the white pine; coarse-writing bark-beetle (*Tomicus calligraphus*) also attacks the white pine, but seems to be more partial to the pitch pine; the white pine-weevil (*Pissodes strobi*) works, as a larva, in the leading shoot, which dies and thus forces the tree to develop a second leader, forming a crook in the trunk or branch attacked; the sawyer (*Monohammus confusor*) is a scourge of Southern pine forests; the pine-destroying beetle (*Dendroctonus ponderosa*) has greatly injured the timber of the Black Hills region by boring in the trunks; and there are many other boring beetles. The Nantucket pine-moth (*Retinia frustrana*) burrows, as a larva, in the wood of the twigs and when in sufficient numbers kills the trees. Of other insects than borers perhaps the caterpillars are most frequently troublesome. Among the best known are the larvæ of two hawk-moths (*Lipara combycoides* and *L. pinetum*); of the imperial moth (*Eacles imperialis*); and of two butterflies (*Thecla niphon* and *Pieris manapia*). These all feed upon the foliage. A leaf miner (*Gelechia pinifoliella*) burrows in the leaves. A gall midge (*Diplosis pini-rigidæ*) forms galls at the bases of the leaf-clusters and its relative (*D. resinicola*) lives in the pitch of the pitch

pine. There are also many saw-flies, plant-lice and scale-insects which destroy the foliage. The best known species are the following:

White Pine (*Pinus strobus*).— In every way this is the most useful species of the genus, combining utility in many directions with ornamental qualities superior to other species, adaptability to many soils and climates and rapidity of growth with productivity. It is an American species, ranging from Newfoundland to Manitoba and southward to Illinois and in the mountains, to Georgia. It attains heights often exceeding 100 feet, sometimes 150 feet, and diameters of four or more. The white or cream-colored wood is soft, straight-grained, somewhat resinous and easily worked. It is very popular for house-building especially for making door and window-frames, shingles, blinds and interior finish. But since the forests of the northern United States and adjacent Canada have been considerably depleted other woods are replacing it for certain purposes.

Georgia, Southern, Yellow, or Long-leaf Pine (*P. palustris*).— As a timber tree this species ranks next to the white pine and is the most important and most widely distributed timber tree of the Southern States. It is found upon the coastal plain from Virginia to Mississippi in a belt about 125 miles wide. It often exceeds 100 feet in height, but rarely more than 120 feet, gradually tapering from a base of about 30 inches. Its orange-brown branches form an open head; its leaves are often more than a foot long and its cones larger than those of species in the same range. The yellow, very resinous wood is the heaviest and strongest of the pines. It is extensively used for ship and bridge building, flooring and for interior finish of houses especially when such is to be left unpainted to show the grain. The tree is the most important source of turpentine, resin, etc., the obtaining of which ranks second only to its timber industry. Its leaves are one of the most important sources of a turpentine-like oil and of pine wool, to obtain which they are boiled in alkalis.

Red, or Norway Pine (*P. resinosa*).—Third in importance among American pines, this species is second in the North to the white pine as a lumber tree. It ranges from Labrador to Manitoba and south to Pennsylvania. Though usually about 75 feet tall and two feet in diameter, it sometimes doubles this height. It occurs most frequently upon dry, sandy soils, where it often forms dense forests. Its light, elastic, resinous, hard wood is durable only when in dry places and is used like that of the short-leaf pine of the South.

Short-leaved Pine (*P. echinata or P. mitis*).— This species ranks second in the South to the Georgia pine and comes fourth in the American list as a lumber tree. Its range is from New York to Illinois and southward to the Gulf States, sometimes excluding other species in large tracts. It attains from 75 to 120 feet in height and a diameter of two feet. The heavy, hard, coarse-grained timber is valued for its strength and durability. It is largely used for framework, railway ties, outside finish of buildings, railway cars, etc. It also furnishes resin. As an ornamental specimen it has been found hardy as far north as Rhode Island.

Loblolly, Frankincense, or Old Field Pine (*P. tæda*).—This species yields coarse-grained but valuable timber used particularly for masts and other ship timbers. It is rich in turpentine though rarely tapped, as the spirits thicken quickly on exposure to the air. It reaches a height of 150 feet with a diameter of 5 feet. It has the same range as the short-leaved pine.

Spruce Pine (*P. glabra*).—A tree of the southeastern States, confined to the coast lands from South Carolina to Middle Florida and westward to Louisiana. It reaches a height of about 130 feet, with a trunk diameter of 4 feet. Its wood is very close grained, but soft and brittle, and lacks durability. It is rarely cut for lumber, but supplies fuel.

Sugar Pine (*P. Lambertiana*).—The most important timber tree of the Pacific Coast, ranging from Oregon to Mexico. It reaches 250 feet in height, with a trunk diameter of 10 feet or more. The long lower trunk is branchless. Its timber is heavy, straight-grained, easily worked and is largely used for furniture and interior finish of houses. It bears edible nuts. Its name is derived from the sugar-like odor of its burning resin.

Bull, or Yellow Pine (*P. ponderosa*).— Perhaps second in importance to the preceding species in the West, its range being from British Columbia to Nebraska and southward to Texas and Mexico. Its wood is coarse-grained and hard, but not durable. It is one of the tallest species, reaching 230 feet with a trunk diameter of 10 feet, but averaging about 150 feet, and 6 feet in diameter.

Slash, Swamp, or Bastard Pine (*P. Caribæa*).—A species associated in range with the Spruce pine, but of a fair quality as lumber, taking a second place in this respect to the Georgia, or Long-leaf pine.

Mountain White, or Silver Pine (*P. monticola*).—Another large species of the West, extending from British Columbia and Idaho to California, and attaining heights of 100 to 150 feet. It resembles the Eastern white pine somewhat in appearance.

Species of Inferior Importance.—The piñon, or nut pines (*P. monophylla, P. edulis* and *P. Parryana*) are small trees in comparison with the foregoing, seldom attaining 50 feet. They are natives of the southwestern United States, where their wood is used as fuel and their large edible seeds as food. The Scotch pine (*P. sylvestris*) is the leading species of Europe, where it often forms extensive forests, frequently mixed with spruce fir, extending into northern and western Asia. Though usually less than 100 feet tall and about 30 inches in diameter, it sometimes attains 120 feet and a diameter of four feet. In its economic uses it resembles the Georgia pine, being good for ship-, bridge- and house-building, though there is considerable variation in the quality of the timber produced upon various soils and by various varieties. It also furnishes much turpentine, resin, etc., and its leaves are used for making pine wool and oil. The timber of the best grades is known as red pine or red deal. Corsican or black pine, or black fir (*P. Laricio*), is a large native of southern Europe and western Asia, which is exceedingly rich in turpentine, etc., and supplies also some Burgundy pitch. Its wood is of little value except for fuel. The Aleppo pine (*P. halepensis*) is a native of the Mediterranean region and western Asia, and rarely exceeds 60 feet in height. It is

useful for shore-planting, yields Venice turpentine, a liquid resin and a timber used in its eastern range for ship-building and similar purposes. The cluster pine or pinaster (*P. Pinaster*) grows on the south European seaboard, and like the Corsican pine is used for shore-planting extensively in southern England along the coast. The Japanese red pine (*P. densiflora*) and Japanese black pine (*P. Thunbergi*) are the two principal Japanese and North China species. They are used for many timber purposes and also for ornamental planting, having developed several horticultural varieties. The Cheer pine (*P. longifolia*) is a Himalayan species which often exceeds 100 feet in height and is valued for its timber, which is often substituted for European deal. Its resin is also obtained in commercial quantities. It has been introduced into California, where it is prized as one of the most decorative of pines, on account of its light, green, drooping leaves. Another Himalayan species, the Bhotan pine (*P. excelsa*), furnishes a close-grained durable wood which on account of its abundant resin is often used for torches. It is about the same size as the preceding species, and somewhat resembles the white pine of America.

Numerous other pines are more or less locally important, as the Philippine Island pine (*P. insularis*), which is one of the leading timber trees of the Philippine Islands, upon the high lands of which it forms large forests; the stone pine (*P. pinea*), one of the most picturesque trees of southern Europe and valued for its almond-flavored nuts and beautifully grained wood; Mexican pines (*P. Montezumæ, P. Ayacahuite* and *P. Arizonica*), the first a white pine, the other two yellow; and the Cembra or Swiss pine (*P. cembra*), a species ranging from the Swiss Alps to northern Russia and Siberia, throughout which country it is valued for its nuts and its "Carpathian balsam."

PINE, Running. See LYCOPODIALES, under FERNS AND FERN ALLIES.

PINE BLUFF, Ark., city, county seat of Jefferson County, alt. 232 feet, on the south bank of the Arkansas River; on the St. Louis, Iron Mountain and Southern and St. Louis Southwestern railroads, and three federal and three state highways; 45 miles south by east of Little Rock. It ships cotton, lumber, hides, livestock, and poultry from the rich farming region nearby. The main factories are cotton gins, compressors and oil mills, saw mills, and furniture factories. The St. Louis Southwestern railroad shops are here, and auto trailers and archery equipment are made here. The annual State Fair is held in Pine Bluff. There is an airport at Toney Field. The State Agricultural, Mechanical and Normal College for Negroes is here, and one high school has a fine concrete stadium. Oakland Park and Memorial Park have playgrounds. Pine Bluff became a city in 1885. It has a mayor and council. Pop. (1940) 21,290.

PINE BLUFF (Ark.), **Engagement at.** Pine Bluff was held 25 Oct. 1863 by Col. Powell Clayton with a Union brigade consisting of the 5th Kansas and 1st Indiana Cavalry regiments, a company of State militia and seven field guns, in all about 575 men. Early in the morning of the 25th General Marmaduke with a division of about 2,500 Confederate cavalry and 12 guns approached the place and demanded its surrender. The outpost commander refused to permit the demand to be sent into headquarters and skirmishing began; the Union pickets being slowly driven in. Meanwhile Clayton, whose troops were quartered in the town, had set 300 negroes at work rolling cotton-bales out of the warehouses and barricading the streets leading into the public square. Artillery was put in position to sweep every avenue of approach; sharpshooters were posted in the buildings; and barrels were filled with water from the river to withstand a siege. The skirmishers were driven in about 8 o'clock and Marmaduke made an attack with his 12 guns and sharpshooters, but making no headway set fire to several buildings near the square to burn Clayton out. Failing in this, Marmaduke at 2 P.M. fell back, leaving some of his dead and wounded, and followed a mile by Clayton. He reported a loss of 40 killed and wounded. Clayton's loss was 11 killed and 27 wounded, and in addition several negroes were killed and wounded. The courthouse and several other buildings were burned and the town wrecked by the Confederate artillery fire. Consult 'Official Records' (Vol. XXII).

PINE FINCH, LINNET, or **SISKIN,** a small greenish finch (*Spinus pinus*), related to the goldfinch, whose home is in northern Canada, and which visits the northern United States in cold winters. These birds frequent coniferous trees and depend upon their seeds, buds, etc., for most of their food.

PINE GROSBEAK, a large northern finch (*Pinicola enucleator*), whose summer home is in northern Europe, Canada and the Rocky Mountains. It measures 9 to 10 inches in length. The head, fore-parts, neck and rump are bright red; back blackish brown, the feathers of this region having red edges; lower portion of the body light gray; wings and tail dusky. Like most winter visitors, it is very tame during the time when it is seen within the United States, which is irregularly in midwinter. Its food seems to consist principally of pine seeds, but it is also fond of those of the birch and alder, and occasionally descends to the ground, where it picks up the seeds of various plants, and probably a few insects. During late summer and winter it has a very pleasing song — clear, sweet and flowing, like that of the purple finch. Four or five eggs of a pale green color spotted with brown are produced; the nest, roughly built of sticks and lined with

feathers, being placed on a branch of a tree near the ground. Consult Coues, 'Birds of the Northwest.'

PINE MARTEN, the American sable. See MARTEN; SABLE.

PINE MOUNTAIN, Engagement of. Gen. J. E. Johnston, commanding the Confederate army opposing General Sherman in the Atlanta campaign, abandoned his lines in front of New Hope Church 4 June 1864 and withdrew to a new position prepared by his engineer, running west from Brush Mountain to Pine Mountain and thence southwest to Lost Mountain. Pine Mountain, an isolated hill rising 300 feet above the surrounding country, formed a salient near the centre of this line. Upon Johnston's withdrawal Sherman occupied the railroad at and near Acworth, brought up supplies, was joined by General Blair, with two divisions of the 17th corps, and on the 10th moved his whole line forward and closed up on the Confederate position. By the 14th General Thomas, with a part of his line, had worked his way close to Pine Mountain, and during the day General Johnston, with Generals Hardee and Polk, two of his corps commanders, were on the mountains observing the movement, when some of Thomas' batteries opened upon the group, killing General Polk. During the night Johnston abandoned Pine Mountain, placing Bates' division, which had occupied it, in reserve, and on the morning of the 15th it was occupied by Howard's Fourth corps. Johnston still held the entrenchments connecting his principal line with Pine Mountain and other detached works, and at noon both Howard's and Hooker's corps advanced against these, Howard on the left of the mountain and Hooker on its right, driving the Confederates to their main works after a sharp engagement. Hooker then pushed against the principal line, Geary's division, supported by Williams', on the left, and Butterfield's division on the right. The Confederate resistance was very strong, and Hooker was repulsed with a loss of 639 killed and wounded. The Confederates, well covered by log breastworks, suffered but slightly. There was brisk and incessant skirmishing until the 18th, Sherman pressing closely and persistently at all points, and on the 19th Johnston was back on a new line, Hood's corps with its right on the Marietta and Canton road; Loring's (formerly Polk's) on the Kenesaw Mountain, and Hardee's on the left, extending across the Lost Mountain and Marietta road. (See KENESAW MOUNTAIN, BATTLE OF; KOLB'S FARM, ENGAGEMENT AT). Consult 'Official Records' (Vol. XXXVIII); Cox, 'Atlanta'; Sherman, 'Memoirs' (Vol. II); The Century Company's 'Battles and Leaders of the Civil War' (Vol. IV).

PINE MOUSE. See FIELD MICE.

PINE SISKIN. See PINE FINCH.

PINE SNAKE, or BULL SNAKE, a large colubrine serpent (*Pityophis melanoleucus*), prevalent in the pine-covered coast region from New Jersey southward, and locally called thunder and lightning snake and bull snake, the latter in reference to the loud hissing and bellowing noise it is able to make by reason of its peculiarly constructed glottis. It is pugnacious and malodorous, but harmless, and feeds on insects, mice, ground squirrels, eggs and young birds, etc., and lays its eggs in a shallow burrow in the sand. This serpent reaches a length usually five and up to eight feet and is white blotched with chocolate brown. Consult the writings of Holbrook, Cope, Abbott and Lockwood, and Ditmars, R. L., 'Reptile Book' (New York 1930).

PINE-TREE FLAG, an American colonial flag used in New England as early as 1700. It was at first red or blue with a pine-tree on a white field. Later it was all white with a pine-tree in the centre, and also the motto "An Appeal to Heaven." This flag was carried by the first war vessels used in the Revolution. See FLAG.

PINE-TREE SHILLING. See NUMISMATICS.

PINE-TREE STATE, a popular name applied to Maine, from the extensive pine forests covering a large part of the State.

PINEAL BODY, a small conical reddish body (frequently called pineal gland), ovoid and conical, an organ attached to the posterior cerebral commissure. It projects downward and backward between the anterior pair of the corpora quadrigemina. Its function was long questioned, the most favored theory being that it was a vestigial sense-organ, probably an eye. A hollow found in the parietal bone in many fossil mammals and reptiles was believed to have been the site of such an organ. This theory is now generally discarded, it having been demonstrated that there is a slight secretion by the body which is, therefore, classed as a gland. It appears to be connected with growth, both physical and mental. Consult McCord, C. P., 'The Pineal Gland in Relation to Somatic, Sexual and Mental Development' (Chicago 1914).

PINEAPPLE, a perennial herb (*Ananas sativus*) of the family *Bromeliaceæ*. It is a native of the American tropics, but has been introduced into warm climates throughout the world. It grows about three feet high, bears long, stiff, sword-shaped, brittle leaves in an elongated rosette, from the centre of which arises the fruit, surmounted by a crown of stiff leaves. After fruiting, if the fruit is removed, another fruiting stem arises, this process being repeated usually for 10 years, after which the field is reset with new plants. The fruits vary in height from 5 to 10 inches, and in weight from 5 to, occasionally, 20 pounds. Until present methods of transportation were employed, the pineapple was a warm-country delicacy, occasionally grown as a greenhouse crop. At the present time few are raised under glass, but immense and annually increasing numbers are shipped from tropical and subtropical fields to the markets of cooler countries, and also are used for canning. The principal fields are the West Indies, Florida, northern Africa, Queensland, Hawaii and Azores Islands.

The pineapple thrives best in an equable climate where the temperature averages between 70° and 80°, and where dry and rainy seasons alternate. Whatever the soil it must be thoroughly drained, even dry. Depth is inconsequential; the plants produce well in the Florida Keys, where the soil is often only one or two inches deep above the coralline rock. They

will withstand months of dry weather but quickly succumb to an excess of moisture, either in the air or the soil. Florida pineapple land frequently contains only a trace of the fertilizing elements considered essential; hence these must be supplied. Dried blood, soda nitrate, dissolved bone phosphate (avoiding rock phosphate), potash as sulphate or carbonate (not the chloride—or kainit), are preferred, and used sparingly. New plants are not grown from seed except for the production of new varieties, since 10 years is often required to bring such plants into bearing. Rattoons, crowns, slips and suckers are used instead. Crowns, or the rosettes of leaves upon the fruits, are little used except when varieties are rare. Suckers develop from auxiliary buds near the ground and produce thrifty plants which usually bear before 18 months old; slips, taken from the base of the fruit, require fully a year longer to reach bearing age. Rattoons, which develop from buds underground are often used to set new plantations but as a rule, suckers are the chief reliance for these as well as for reset fields. The land having been prepared, the plants are set in checks 18 to 36 inches apart, with alleys left at intervals of six or eight feet. Cultivation consists in keeping the surface loose with a scuffle hoe. With reasonable care a plantation should bear for 10 years without resetting. The fruits are gathered about a week before full maturity, wrapped individually in brown paper, packed firmly in half-barrel or barrel crates and shipped.

Pineapple sheds are built of slats upon a framework of posts and beams high enough to permit a man to stand upright under them. The slats are about three inches apart, to permit the ingress of light. The sheds protect the plants from excessive heat and from frost, and they improve the quality of the fruit. Only choice varieties are so grown, the cost of erection, about $500 an acre, being prohibitive of inferior sorts.

The principal enemies of the pineapple are red spider (*Stigmæus floridanus*); scale insects (*Diaspis bromeliæ*); and mealy bugs (*Dactylopius citri,* etc.). The first appears upon the tender leaf bases and causes rot. A handful of tobacco-dust placed in the crown of the plant is effective; rains dissolve and carry the solution to the infected parts. Resin wash, whale-oil soap and kerosene emulsion are used for the scale; these and the tobacco are used for the mealy bugs. The scale usually appears on the under surfaces of the leaves, but produces a yellow spot on the upper; the mealy bugs attack the bases of the leaves below ground, the buds and the fruit.

Blight or *wilt* is said to be due to a soil fungus at the roots. Removal and resetting are practised, though plants of valuable varieties are sometimes trimmed and replanted. *Sanding,* which follows the filling of crowns of young plants with sand, may be prevented by filling the crown after planting with cottonseed meal, or other loose material which will not prevent growth but will keep out the sand. *Spike,* non-expansion of the leaves, is due to unfavorable conditions of the soil. Change of fertilizer is recommended. *Heart rot* or *bitter heart,* which often accompanies wet seasons, is of unknown origin. The affected part, the heart, looks watery, and the whole fruit becomes bitter. If not serious in nearly mature fruits the pineapples may be marketed; otherwise destroyed. Consult Bailey, 'Cyclopedia of Standard Horticulture' (1930); Hawaiian Pineapple Company, 'Sixty Pictures and a Few Paragraphs' (San Francisco 1927); 'L'Ananas,' in *Nature* (Paris 1930); 'The Pineapple in the Americas,' in *Pan American Union Bulletin* (1918).

PINEAPPLE FIBRE. See FIBRE.

PINEDA, pē-nā'dä, Philippines, pueblo of Rizal, Luzón. See PASAY.

PINEHURST, pīn'hėrst, N. C., village in Moore County 62 miles southwest of Raleigh and 125 miles from the seacoast, on two federal highways and one state highway. It is 536 feet above sea-level. Railroad connection is made from Pinehurst over the Aberdeen and Asheboro Railroad with the Seaboard Air Line at Aberdeen and the Southern Railroad at High Point. It is a winter resort, founded in 1895 by James W. Tufts of Boston. It embraces a large tract of country. There are three 18-hole golf courses and two polo fields, a shooting preserve of 50,000 acres, a dairy and poultry farm and a large market garden. Pinehurst is the favorite winter training place for harness horses. The location was selected for its scenery and healthfulness. Pinehurst is not incorporated as a town; it is operated as a private business enterprise under the corporate laws of the state. In winter the population is approximately 3,800, out of season, about 550.

PINEL, pē-nĕl, **Philippe,** French alienist: b. Saint André d'Alayrac, 20 April 1745; d. Paris, 26 Oct. 1826. He studied medicine in Toulouse, in Montpellier and in Paris, where he had to teach philosophy and mathematics to keep himself alive; in 1791 became directing physician in the insane asylum at Bicêtre and in 1794 at the Salpétrière; and in both these institutions introduced gentle, kind treatment in place of the barbarities he found. In his book, 'Sur l'Alienation Mentale' (1791), he first suggested moral remedies for the insane, so that this work is the foundation of modern psychiatry. His 'Nosographie Philosophique' (1798) created an epoch in French medicine. He became a member of the Institute in 1803 on Cuvier's death. Suspected of liberal political views he was removed from his post in the medical school in 1823.

PINERO, pĭ-nĕr'ō, SIR **Arthur Wing,** English dramatist: b. London, 24 May 1855. His ancestors, the Pinheiros, Portuguese Jews, settled in England in the 18th century. He was a solicitor's clerk for several years; went on the stage in 1874, appearing first in Edinburgh; became a member of Henry Irving's company soon afterward, playing Claudius in 'Hamlet'; and had written a farce, 'Two Can Play at that Game'; a successful comedietta, '£200 a Year'; the one-act plays, 'Daisy's Escape' and 'Bygones,' which were curtain-raisers for the Irving company at the Lyceum; and in 1881 'The Squire' and 'Imprudence' before turning himself in 1882 entirely to dramatic authorship. His earliest plays after that date show a striving after real characters — none too successful, for example, in 'The Magistrate' (1885). The beginning of his naturalistic power was to be

seen not only in the well-known farces of the next two years, 'The Schoolmistress,' 'The Hobbyhorse' (1886), and 'Dandy Dick' (1887), but in the tragedy called 'The Weaker Sex,' first played in 1888. 'Sweet Lavender,' a pretty, rather unpleasant, very unreal and quite uncharacteristic play, was written in 1888. 'The Profligate,' with its Puritan theme of the impossibility of burying a wicked past, was dramatically powerful but poorly written. It was followed by the weak farces, 'The Cabinet Minister' and 'The Times,' in 1891 by 'Lady Bountiful,' and in 1893 by 'The Second Mrs. Tanqueray,' which showed great gain in literary ability and in dramatic machinery. Between them and 'The Notorious Mrs. Ebbsmith' (1895), no doubt his best play, came again a farce 'The Amazons'; indeed it seems that after every serious effort he returned to the farce. Pinero's later works include 'The Benefit of the Doubt' (1895); 'The Princess and the Butterfly' (1897); 'Trelawney of the Wells' (1898); 'The Gay Lord Quex' (1899); 'Iris' (1901); 'Letty' (1903); 'His House in Order' (1906); 'The Thunderbolt' (1908); 'Mid-Channel' (1909); 'Mind-the-Paint Girl' (1912); 'Widow of Wasdale Head' (1912); 'Playgoers' (1913); 'The Big Drum' (1915); 'Mr. Livermore's Dream' (1917); 'The Freaks' (1918); 'The Enchanted Cottage' (1922); 'A Private Room' (1928); 'Two Plays' ('Dr. Harmer's Holidays' and 'Child Man') (1930). See THUNDERBOLT, THE. He was knighted in 1909. He died, London, 23 Nov. 1934.

PINEVILLE, Ky., city and Bell County seat; alt. 1,025 feet; on the Cumberland River; 11m. N. of Middlesboro; on the Louisville and Nashville Railroad. It is in coal-and-lumber country, and is an important shipping point. Here the Cumberland Valley Music Festival is held each spring. Near by is Pine Mountain State Park, with curious rock formations. Pop. (1930) 3,567; (1940) 3,882.

PINEVILLE, La., town in Rapides Parish; alt. 95 feet; on Red River, opposite Alexandria (q.v.), the parish seat; 186m. NW. of New Orleans; on the Louisiana and Arkansas Railroad, with airport three miles south. In Pineville are Louisiana College (Baptist, coeducational); Central Louisiana State Hospital; Huey P. Long Charity Hospital; and Pineville National Cemetery. Pop. (1930) 3,612; (1940) 4,297.

PING PONG or TABLE TENNIS, originated about 1881 by some English army officers in India, was played with crude, improvised rules and equipment, consisting of a large table with a row of books across for a net, a champagne cork for a ball and cigar box lids for paddles. Popularized after the turn of the century with the advent of the celluloid ball, the fad soon waned, except in Hungary where, from an innocuous parlor pastime, it was developed into a vigorous sport. Revived after the World War, the game's popularity has grown apace. The game itself has been accelerated and changed into a more pleasing spectacle, offering the players vigorous exercise plus entertainment. Much of the progress of this pastime is due to the International Table Tennis Association, founded in 1926, which in conjunction with its affiliated national organizations, controls the rule making and conducts annual world's championship matches for both sexes. In the United States, table tennis was revived in 1925 by the American Ping Pong Association, formed by a commercial concern to promote the sale of their equipment. For this reason the game became widely known as Ping Pong.

The game is played by striking a small celluloid ball of between 4½ to 4¾ inches in circumference, weighing between 37 and 41 grams, with a fan-shaped paddle over a net 6 inches high fixed across the middle of the table width and projecting 6 inches on either side. The table is 9x5 feet, its upper surface being 2½ feet from the floor, and is of such resilience that a standard ball dropped from a height of one foot will rebound to a height of from 8 to 9 inches. The server strikes the ball with the paddle, standing behind the table and an imaginary extension of the side lines, causing it to bounce first in his court and then in his opponent's court. After service the ball is half volleyed back and forth as in Lawn Tennis until either player shall miss. Scoring is by points, the disposition of a point being involved every time the ball is served. Twenty-one points constitutes a game. Service changes every five points until either player shall have made 21 points, except that if the score should reach 20 all, service is alternated with each point, and as at deuce score in Lawn Tennis the winner is the first player to score two points more than his opponent. In service, a ball which after bounding once in server's court strikes the net or net posts and drops in opponent's court is called a «LET,» and does not count. After service and during the half volleys, a ball striking the net or net posts before striking any other object, is good if it drops directly into opponent's court. The ball may be struck with as great or little force as circumstances permit or dictate, provided it is struck with the hand holding the paddle below the wrist. It is not permissible to rub the ball against the paddle while still holding the ball during service.

GEORGE E. EDINSON,
Advisory Committee United States Table Tennis Association.

PING-YANG, or HEIJO, Korea, a city on the Ta-tong River about 40 miles above its mouth and about 120 miles northwest of Seoul. It extends for two and a half miles along the river bank, is surrounded by fortified walls 20 feet high and is considered of great strategic importance, being called the «Key of Korea.» Ping-Yang is said to date from 1122 B.C., when the historic Ki-Tse or Kija, ancestor of Confucius, landed here from China, and laid the foundations of Korean civilization. His tomb is one of the city's sacred shrines. A fine monument has been erected to the Chinese warrior Tso who ruled their forces and perished here. Pop. 127,103, including 25,559 Japanese.

PINGUIN, the West Indian wild pineapple largely grown in the Antilles as a hedge-plant. See BROMELIA.

PINK-EYE, a disease of horses, frequently suffered in the Southern States, but rare in the North. It is allied to influenza and scarlet fever in man. It usually breaks out in wet, cold weather, and its chief symptoms are, besides the redness of the eye to which it owes its name, loss of appetite, feverishness, quickened pulse and perhaps stiffness of the limbs and

constipation. It is likely to be epidemic in limited districts, because spread by the aid of the midges of the genus *Hippelates,* which hover about the eyes of diseased horses and carry pathogenic germs to the next animal they visit. It usually runs its course in 10 days or less, and is generally not fatal. In treating this disease an antiseptic wash for the eyes should be used; cardiac stimulants may be required and strict attention must be given to all sanitary care.

PINKERTON, pĭng'kẽr-tŏn, **Allan,** Scottish-American detective: b. Glasgow, Scotland, 25 Aug. 1819; d. Chicago, Ill., 1 July 1884. In Scotland he had learned the trade of cooper and after his arrival in the United States set up a cooperage at Dundee, near Chicago. In 1842 he came to Chicago, Ill., and was appointed its first detective in 1850. In the same year he established a detective bureau, afterward well known from its use by predatory capitalistic interests to crush trades-unionism. He organized the secret service division of the United States army in 1861, was made its first chief and later formed and directed the secret service department of the Gulf until the end of the war. While employed by the Wilmington and Baltimore Railway he discovered a plot to assassinate Lincoln on the way to Washington (1861). He was very successful in his detective work, being particularly skilful in the detection of bank and express thieves and the recovery of the money taken. He also broke up the "Molly Maguire" band of Pennsylvania. Among his writings were 'The Spy of the Rebellion' (1883); 'Thirty Years a Detective' (1884); 'History and Evidence of the Passage of Abraham Lincoln from Harrisburgh, Pa., to Washington, D. C., on the 22d and 23d of February 1861' (1891); 'Strikers, Communists and Tramps' (1878), in which Pinkerton's lack of sympathy with the toiling masses is evidenced as also his unholy alliance and sympathy with the capitalists of his day. As manager and hirer of "strike-breakers" during the great railroad strikes of 1877 many of his methods were of questionable morality, although always strictly within the law, while many of his operations actually incited others to the crimes which were then "detected." His writings are a sad commentary on the period which tolerated both him and his methods.

PINKERTON, John, Scottish antiquary: b. Edinburgh, 17 Feb. 1758; d. Paris, France, 10 March 1826. In 1781 he settled in London, where in 1783 he published 'Select Scottish Ballads,' a part of the supposedly ancient contents of which was from his own pen. He was for a time editor of the *Critical Review;* and he turned out a large number of volumes, original and compiled, the former showing more of skill in research than literary merit. Among works editorially prepared by him were 'Ancient Scottish Poems' (1786), sometimes declared to have been a forgery, though the manuscripts are in the Pepysian library at Cambridge; and a 'Collection of Voyages and Travels' (1807–14), a voluminous (17 vols.) and, in its day, valuable publication.

PINKERTON, William Allan, American detective: b. Dundee, Ill., 7 April 1846; d. 11 Dec. 1923. He was a son of Allan Pinkerton. During the Civil War he was in the United States Secret Service and afterward entered his father's office. On the death of his father, in 1884, he became head of the agency and extended its operations throughout the world.

PINKNEY, pĭnk'nĭ, **William,** American diplomat: b. Annapolis, Md., 17 March 1764; d. Washington, D. C., 25 Dec. 1822. He was educated at King William's Seminary, studied law under Samuel Chase and was admitted to the bar in 1786. While a member of the Maryland legislature he assisted in the ratification of the Federal Constitution in 1788 and in the same year was elected to the house of delegates. As United States commissioner to England under the Jay Treaty he secured in 1796 a claim of $800,000 for the State of Maryland against the Bank of England for losses and damages to American merchants caused by the English government. Afterward he engaged in law practice in Baltimore and in 1804 became attorney-general of Maryland. In 1806 he was sent as Minister Extraordinary to England, where in conjunction with James Monroe he treated with England in regard to the latter's violation of the rights of neutrals. He was Resident Minister to England in 1807–11 and in the latter year was appointed Attorney-General of the United States. He fought in the War of 1812, served in Congress in 1815–16 and in 1816 was appointed Minister to Russia and Special Envoy to Naples. In 1818 he resigned and resumed his law practice in Baltimore and in 1820 was elected to the United States Senate. Consult Wheaton, 'Life, Writings and Speeches of William Pinkney' (1826).

PINKROOT, the rhizome of a loganaceous medicinal woodland (*Spigelia marilandica*) of the United States, which is bitter, anthelmintic, toxic, dilates the pupil, etc.

PINKS, a genus (*Dianthus*) of mostly perennial herbs of the order *Caryophyllaceæ.* The species, of which about 250 have been described, are natives of the Eastern hemisphere, especially Europe and western Asia. Their jointed stems, which grow in tufts, bear grass-like leaves and terminal, often fragrant, flowers either in clusters or solitary. Their popular name is derived from the prevailing color of the flowers, though white and purple are common in garden varieties. For centuries the pinks have been cultivated, their flowers, hardiness and ease of cultivation rendering them garden favorites. They are easily propagated from seeds or cuttings; thrive in well-drained, rather light loam; and the perennial kinds mulched during the winter with loose litter, straw or brush to prevent the formation of ice around the stems and to hold the snow and keep the frost in the ground until late in the spring. The seeds are usually sown under glass in early spring and the plants set in the garden when the weather has become settled. Cuttings are used for double and other choice varieties. Seeds sown in late summer will produce plants for early spring blossoming if mulched during the winter.

Among the best-known species are the following: Common grass, or garden, Scotch or pheasant's eye pink (*D. plumarius*), a general favorite in old-fashioned gardens; sweet-william (*D. barbatus*), one of the oldest and most popular of garden flowers; clove pink, picotee,

grenadine or carnation (*D. caryophyllus*), popular in various forms either as a garden or a greenhouse plant (see CARNATION); maiden pink (*D. deltoides*), popular as an edging plant; *D. prolifer* and the Deptford pink (*D. armeria*), well-known weeds naturalized in the Eastern States; Chinese or Indian pink (*D. chinensis*) and *D. superbus*, also popular garden species. In rock gardens *D. alpinus*, *D. neglectus* and *D. glacialis* are favorites. The new annual hybrids show improved intensity of color and elegance of form, besides profusion of bloom.

PINNA, or **WING-SHELL**, a genus of bivalve mollusks of the family *Aviculidæ* with wedge-shaped shells of a horny, delicate structure, the hingeless beaks forming a pointed extremity. The foot is long and grooved and secretes a large byssus of strong, silky texture. The genus is represented by the *Pinna nobilis* of the Mediterranean Sea, from whose byssus in past days the Neapolitans, Sicilians and Maltese used to weave quantities of durable silk. Frequent mention is made of the fabric by Latin authors. Pope Benedict XV in 1754 had a pair of stockings made from this "silk." Many other species are known in various parts of the world, including the shores of the Gulf of Mexico.

PINNACE. One of the boats of a man-of-war formerly used to carry the officers to and from the shore. It was smaller than the launch, but larger than the cutter, and was rowed by from 10 to 16 oars. Also, anciently, any small sailing craft.

PINNACLE, *in architecture*, any small, tall, more or less ornate terminating upper point of a building, tower, etc.; the topmost finishing piece of a high point, as on a gable, buttress or spire. The term pinnacle is not very definite, but it is used to describe miniature towers or tops of towers that are too conspicuous to be termed finials.

PINNATED GROUSE. See GROUSE.

PINNIPEDIA, a suborder of *Carnivora*, the seals, especially adapted in the structure of their limbs to an aquatic existence, as the name indicates. Both pairs of limbs, and especially their proximal segments, are very short, and the distal part flattened, webbed and paddle-like. The hind limbs are placed very far back and are very peculiar in that the first and fifth toes are stout and as long or longer, instead of shorter, than the others. The head is usually short and rounded, the neck short, the trunk thick and fusiform and the tail rudimentary. The teeth are simpler in structure than in most carnivora, the molars and premolars being either nearly simple cones or crowned with numerous small-pointed tubercles; the incisors are reduced in size and often in number, but the canines of the males are usually enlarged, and in the walruses become enormous tusks. The brain is large and much convoluted, and the eyes large and possessed of a very human expression. All of the pinnipeds spend the greater part of their lives in the water, swimming with great speed and dexterity; but the peculiar structure of their limbs ill adapts them for terrestrial progression, which is accomplished in an awkward shuffling manner with severe contortions of the back. They are chiefly marine, frequenting the coasts of colder climates, though some species are tropical and others enter fresh water. Some of the species spend much time far out at sea, but land on islands for the purpose of mating and bearing young. Most of them are carnivorous, feeding upon fishes, mollusks and crustaceans, but a few subsist in part upon marine algæ. The pinnipedia have been derived from land animals, probably from the bears, and their adaptation to an aquatic habitat is not nearly so extreme as in the whales. Three families are usually recognized: The *Otariidæ*, or eared seals, which have a small, valvular, external ear and include the sea-lions and sea-bears. The *Phocidæ* have no external ear, and are the most completely aquatic members of the suborder. Here belong the common harbor-seal of the north Atlantic coast, the hooded seal, the sea-elephant and numerous other species. In the *Trichechidæ* is included only the walrus, in many respects the most remarkable of the entire group. Consult Allen, J. A., 'History of North American Pinnipeds' (1880). See SEALS; ELEPHANT-SEAL; WALRUS.

PINOCHLE, pē'nō-kl (corruption of Binocle).

PINOCLE, or **PENUCHLE**, a game of cards very popular among the Germans in America. The object of the game, which may be joined in by either two, three, or four persons, is to secure 1,000 points. The game is played with two full packs of cards, mixed, from which the twos, threes, fours, fives, sixes, sevens and eights have been removed. In 64-card pinocle the sevens and eights are retained. This is the schedule of "points":

Eight aces count	1,000
Eight kings count	800
Eight queens count	600
Eight jacks count	400
Two queens of spades and two jacks of diamonds (double penuchle) count	300
Ace, ten, king, queen and jack of trumps count	150
Four aces of different suits count	100
Four kings of different suits count	80
Four queens of different suits count	60
Four jacks of different suits count	40
Queen of spades and jack of diamonds (penuchle) count	40
King and queen of trumps (royal marriage) count	40
King and queen of a suit not trumps (marriage) count	20
Nine-spot of trumps counts	10

The relative value of the cards is: Ace counts for 11 points, 10-spot counts for 10 points, king for four, queen for three, jack for two and the nine counts nothing. The last trick counts 10 points for the player who takes it. The total points, therefore, of the cards and last trick combined amount to 250. Four-handed pinocle is usually played two against two as partners, sitting opposite one another. The cards are all dealt out, four at a time, each played receiving 12, and the last card is turned up for trump. If two are playing, the 25th card is trump. If a nine is turned up the dealer is credited at once with 10 points; if any other card is turned up either of the other players who holds a nine of trumps may exchange it for the trump card and claim 10 points, the player sitting on the left-hand side of the dealer having the preference. Each player then melds whatever he has in his hand and the partners score together. The eldest hand then leads a card for the first trick. In

every trick each player must follow suit; if he cannot he must trump; if neither is possible, he may play any card he pleases; he must take the trick if he can; the player who takes the trick leads for the next. When either side reaches 1,000 points the scorer calls "game," and the balance of the hands are void. In three-handed pinocle 16 cards go to each player, four at a time; and each player keeps his own score. In auction pinocle no trump is turned, each player in turn from the dealer's left bidding a number of points for the privilege of naming the trump. If all the players pass this privilege the dealer is obliged to bid 20 and name the trump. Consult Foster, R. F., 'The Laws of Pinocle' (New York 1908).

PINOS, pē'nōs, Mexico, town in the state of Zacatecas, 45 miles west of San Luis Potosi, and capital of the administrative district of Pinos. It is about 7,700 feet above the sea-level, lying on the eastern slope of the Cerro de Candelaria; is centre of a rich silver and gold-mining district, and produces an excellent grade of mescal. The population of the district is estimated at 50,000; of the town, 7,500.

PINSUTI, pēn-soo'tē, **Ciro,** Italian composer: b. near Siena, 9 May 1829; d. Florence, 10 March 1888. He was trained as a musician by his father and by Rossini; became a singing teacher in London and Newcastle in 1848 and professor of singing in the English Royal Academy of Music in 1856. He wrote the successful Italian operas 'Il mercante di Venezia' (1873); 'Mattia Corvino' (1877), and 'Margherita' (1882); as well as a 'Te Deum' (1859), on the annexation of Tuscany to Italy, and several fine songs.

PINT, a measure of capacity, the eighth part of a gallon. See Weights and Measures.

PINTAIL, or SPRIGTAIL DUCK. See Duck.

PINTO, pēn'tō, **Alexandre Alberto da Rocha Serpa,** Portuguese explorer in Africa: b. Castle Polchras, 10 April 1846; d. Lisbon, 28 Dec. 1900. He was educated in America, where he lived with his father, 1848–58, and then in the Lisbon Military College, whence he entered the Portuguese army in 1864. He served in Mozambique and in 1877–79 explored the country between Mozambique and Pretoria, in 1885 the region west of Lake Nyanza, and in 1889, having been named governor of Mozambique, the region round the Shire River. His bold attitude toward English expansion in Africa and his efforts to spread Portuguese influence made his recall necessary in 1890 because of a protest from England. His trip across Africa in 1877–79, the fourth crossing from west to east, was his greatest feat and is described in his book 'How I Crossed Africa' (1881).

PINTO, Fernao Mendez. See Mendez Pinto.

PINTSCH (pĭnch) SYSTEM, a system of compressed gas formerly used for lighting railroad cars and automobiles but superseded by electricity. Nearly every railroad system adopted it. The gas was made largely from oil and compressed, 125 pounds of pressure, to the square inch giving one foot of oil gas, equal to the illuminating power of five feet of coal gas. Petroleum oil was "cracked" at a high temperature, yielding an oil gas rich in illuminating power; by washing, the forming of tar is obviated. The lamps used were of special design, each having from four to six burners. The system was also applied to lighting harbor buoys and found advantageous.

PINTURICCHIO, pēn-too-rēk'kē-ō ("the good little painter"), easel name of Bernardino de Betto Bagio, Italian painter: b. Perugia, 1454; d. Siena, 11 Dec. 1513. It is thought that he was a fellow-student of Pietro Perugino under Niccolo da Foligno, and he was assisting Perugino (his senior by only eight years), at Rome (1484) in executing the frescoes of the Sistine Chapel for Innocent VIII. Among his other Roman patrons were Sciarra Colonna and Alexander VI; for the latter he painted a series of scenes from the life of Saint Bernard in the church of Ara Cœli, and five frescoes in the Vatican. He returned to Umbria in 1498 and works of his are extant in Perugia, Orvieto and Spoleto. Cardinal Francesco Piccolomini, afterward Pius III, on completing his cathedral at Siena, invited him to decorate the library of that building (1502). The walls he frescoed with scenes from the life of Pius II, the cardinal's uncle, and the roof with arabesques and mythological compositions. Raphael, then 19, accompanied him to Siena, but whether he took part in the execution of the frescoes is uncertain. These works are brilliant in conception and execution and are considered the finest of his frescoes. Fresco-painting was indeed his strongest point; he understood well the decorative resources of his art, and was master of ornament. He left few easel pictures and these are scattered through the chief public and private galleries of Europe. His 'Return of Ulysses' was sold in 1874 for $10,761.50, and his three scenes from the life of Griselda for $3,620. The last of his known works, painted in 1513, is the 'Procession to Calvary,' now in the Casa Borromeo, at Milan. Sigismodo Tizio, parish priest at Siena, has left a true but tragic account of his death. When confined by sickness to his bedroom his wife locked him in, went off with her lover and left her husband to perish by hunger. In the history of painting he is to be looked upon as the link between Perugino and Raphael and some pictures of his have been attributed to each of these masters. He bore a high character among his fellow-citizens and was elected decemvir of Perugia in 1501.

PINWORM, a small parasitic nematode worm (*Oxyurus vermicularis*), usually less than half an inch in length, which infects the human rectum and large intestine, especially in children. Pinworms travel down the bowel and cause irritation about the anus, which provokes the victim to scratching. The eating of fruit, etc., handled by one suffering from pinworms is a probable means of infecting another.

PINY RESIN, TALLOW, or VARNISH. See Dammar.

PINZON, pēn-thōn', **Martin Alonzo,** Spanish shipbuilder and navigator: b. about 1440; d. 1493. He was a native of Palos, and at the summons of Prior Juan Perez of La Rábida held a conference with Columbus (q.v.) and decided to aid the latter in his first voyage.

In this expedition he sailed in command of the *Pinta,* the second caravel, but deserted Columbus off the coast of Cuba 20 Nov. 1492. The *Pinta* was the fleetest of the three vessels, and the purpose of Pinzon's treachery was evidently that he might first reach Spain and there make exaggerated claims for himself. He was the first to reach Haiti (Hispaniola), where he traded and found gold, and where when he fell in with Columbus, 6 Jan. 1493, he explained that stress of weather had separated him from the other ships. In a fierce storm during the return (12–18 Feb. 1493), the *Niña* and *Pinta* were parted, and the *Pinta* reached Bayonne, a Galician port. Thence Pinzon dispatched to the sovereigns an account of the discovery, claiming much. But this was quite disregarded, and when he reached Palos it was only to find the admiral already there. A letter from the monarchs forbade him to appear at court, and it was said that chagrin hastened his death.

PINZON, Vincente Yañez, Spanish shipbuilder and navigator: b. about 1450; d. about 1525. He was a brother of Martin Alonso Pinzon (q.v.) and a native of Palos, and set sail from there on Columbus' first voyage as commander of the third caravel, the *Niña.* But he is better known for a voyage he undertook in 1500, during the course of which he discovered the Brazilian coast and the mouth of the Amazon. He made with Juan Diaz de Solis two voyages, one probably in 1497 to the bay of Honduras, the other in 1508–09 along the eastern coast of South America as far as the Colorado River, lat. 40° S.

PIOLET, pē'ō-lā, **Jean-Baptiste,** French clergyman and author: b. Courteix, Corrèze, France, 24 June 1855. He was educated at the college of Ussel and the seminaries of Servières and Tulle and various Jesuit scholasticates. In 1876 he became a member of the Society of Jesus and was ordained to the priesthood in 1888. In 1890–91 he was laboring as missionary in Madagascar and in 1898 delivered a course of lectures on Madagascar at the Sorbonne. Subsequently Dr. Piolet was missionary in Wales and at Paray-le-Monial, and for some years has been stationed in Paris. He was awarded three prizes by the French Academy and the Academy of Moral Sciences and has attended various colonial congresses and the sessions of the International Colonial Institute. His publications include 'Le catholicisme en Indo-Chine'; 'La religion catholique en Chine'; 'L'Eglise catholique aux Indes'; 'Madagascar, sa description, ses habitants' (1895); Madagascar et les Hova' (1895); 'Empire colonial de la France: Madagascar'; 'Douze leçons sur Madagascar' (1898); 'De notre emigration'; 'L'Eglise catholique dans le continent noir,' with C. Vadot; 'Nos missions et nos missionaires; 'Questions d'Angleterre' (1906). He organized and directed 'Les missions catholiques Françaises au XIXe siècle' (6 vols.), and contributed to *Etudes, Le Correspondant, La Revue Hebdomadaire,* etc.

PIOMBINO, pē-ŏm-bē'nō, Italy, (1) a former principality of Tuscany, lying between Siena and the Mediterranean, opposite the island of Elba, from which it is separated by the channel of Piombino. Its extent was about 216 square miles, with a population of 25,000 at the time of its incorporation with the kingdom of Italy (1860). It was originally a fief in the possession of the Appiani family, which, after a rule extending over 300 years, sold it to the Buoncampagni family in 1634. In 1804 Napoleon granted it to his sister Eliza, Princess Baciocchi; but she was rejected by the Congress of Vienna, and the old family restored. Piombino now forms part of the province of Pisa. (2) A seaport town of Pisa, 40 miles south-southeast of Leghorn, at the end of Monte Massoncello peninsula. Elba is visible six miles across the channel. Pop. with commune about 8,700.

PIOMBO, pē-ŏm'bō, **Sebastiano del,** Italian painter: b. Venice, 1485; d. Rome, 21 June 1547. His family name was Luciani. Having renounced music, to which he had early devoted himself, for painting, he studied under Giovanni Bellini and Giorgione, the latter of whom he especially imitated. Something of the fine coloring of Giorgione appears in the figure of Saint Chrysostom writing, in the altarpiece of the church of that name at Venice, which is Piombo's earliest fresco. In 1510 he went to Rome and became acquainted with Michelangelo, whose mastery of form he tried to make his own and to combine with his own Venetian skill in coloring. He also vied with Raphael, and the so-called 'Fornarina' in the Uffizi and the 'Saint Dorothea' at Berlin were both for a long time attributed to Raphael. When Raphael had painted his 'Ascension,' Sebastiano was induced by Michelangelo to attempt to surpass it by the 'Raising of Lazarus,' considered his greatest work. His 'Martyrdom of Saint Agatha' also ranks among the masterpieces of the Italian school. His chief merit, however, lay in single figures and portraits. His 'Pietro Aretino' and his 'Clement VII' are admirable likenesses and perfect in coloring. He was high in favor with Clement: who created him one of the keepers of the Papal seals, *Frate del Piombo;* hence his surname, the seals attached to the papal bulls being at that time of lead (*piombo*). This post made it necessary for him to assume the clerical habit, and from that time he painted but little. He invented a peculiar method of painting in oil on walls, in which manner there is a 'Scourging of Christ' to be seen in Saint Pietro in Montorio.

PIONEERS, in old-time warfare, a detachment of soldiers equipped with pickax, spade, etc., in the proportion of 10 to every battalion of infantry, whose duty it was to clear and repair roads, bridges, etc., as far as possible, for troops on the march. They were placed at the head of the battalion of which they form a part and commanded by a pioneer sergeant. They have long been replaced by the engineer corps. However, the engineers are sometimes termed the «pioneer battalion.»

PIOTRKOW, pēy-ŏtr'kŏv, German Poland, (1) city of a district of the same name, 90 miles by rail southwest of Warsaw. Cotton and wool spinning, with the manufacture of agricultural implements, are the chief industries. The town dates from before the 12th century and is one of the oldest in Poland. In its ancient castle, still standing, diets were held in the 15th and 16th centuries and the kings elected. After being captured by the

German army in 1915, the fortifications were strengthened. Pop. (1921) 48,948. (2) The district in the west of Poland, south of the county of Warsaw, has an area of 4,730 square miles. The surface is undulating and diversified by hills from 1,000 to 1,600 feet high, extending southwest to northeast. It is rich in coal deposits and iron; zinc and lignite are also mined. Agriculture and stock-raising are important industries and there are manufactures of textiles and ironware on a moderate scale. The district is now part of Lodz County.

PIOUS FUND OF CALIFORNIA, an endowment fund dating from 1697 and created from voluntary donations and subscriptions received or solicited from various benefactors and religious bodies, chiefly in Mexico, to be applied to the propagation of the Catholic faith in California. The first chief contributors who each gave $1,000 were Don Alonzo Davalos, Condé de Miravalles and Don Mateo Fernandez de la Cruz, Marquez de Buena Vista. By their example others were induced to subscribe and in a short time $15,000 more were made up, $5,000 in cash and $10,000 in promises. On 5 Feb. 1697 the necessary authority was conferred on Fathers Juan Maria Salvatierra and Francisco Eusebio Kino of the Jesuit order, to undertake the invasion of California on the express conditions: 1. That possession of the country was to be taken in the name of the Spanish crown, and 2. That the royal treasury was not to be called on for any of the expenses of the enterprise. Don Pedro Gilde la Sierpe, treasurer of Acapulco, offered the use of a galliot to transport the missionaries to their destination, and the gift of a small boat or launch. Considering the remoteness and isolation of the field, it was determined to establish a separate special fund or capital, the income from which should form a permanent endowment for the missionary church. Toward this latter object the first recorded contribution is from the congregation of Nuestra Señora de los Dolores, of the city of Mexico, which contributed $10,000 and Don Juan Caballero y Ozio who donated $20,000 more, besides giving Father Salvatierra the satisfactory assurance, that in any unforeseen emergency, he might draw on him for whatever money he needed and he would honor his drafts, large or small. This endowment fund, commenced by the pious liberality of the society and the individual just named, was increased by subsequent donations. The capital was invested as securely as possible, and as an income of $500 yearly was deemed necessary for each mission and 5 per cent was the current rate on safe investments, a capital of $10,000 was made the basis of each new mission founded. From 1698 to 1757 13 missions were founded on the peninsula and these sums of money forming a considerable capital, received by common consent the name of "The Pious Fund of the Missions of California," or more briefly, the "Pious Fund of California." In 1767 the Jesuits were expelled from the Spanish dominions; the Pious Fund was seized by the Crown and transferred to the Franciscans under whom from 1769 to 1823 the 21 missions in upper California were founded. On the declaration of Mexican independence, Mexico succeeded the Crown of Spain as trustee of the Pious Fund and it continued to be managed and its income applied as before, down to 19 Sept. 1836, when the Mexican Congress passed a law attaching an endowment of $6,000 per year for the erection of a bishopric and conceded to the incumbent when selected and his successors, the administration and disposal of the "Pious Fund." On 8 Feb. 1842 this law was abrogated by a decree of Santa Ana and the capital of the Pious Fund after about 160 years of separate existence "was engulfed in the maelstrom of the Mexican treasury." Not, however, before Don Pedro Ramirez, the venerable agent and attorney of the fund, had drawn up in duplicate his detailed "instruccion circunstanciada" of the properties, and the Mexican government had stipulated to pay to the Church 6 per cent in perpetuity on the principal. The war of 1847 between the United States and Mexico resulted in the transfer of Upper California, and Mexico ceased paying interest. In 1868 the Roman Catholic Church in California made a claim, based on Don Pedro's data for 21 years' interest — nearly a million dollars — and after seven years a commission at Washington, D. C., gave a decision that the interest of the fund should be equally divided between the Church in Mexico and in California and that Mexico should set aside half of the annual payment. This was the famous Sir Edward Thornton decision. The Mexican government paid the award decreed by Sir Edward, but did not pay anything after. In 1902 the matter was brought before the Hague International Court for arbitration. The decision was given: that the Mexican government shall pay to the government of the United States in the claim on behalf of the archbishop of San Francisco, $1,420,682.67 in money of the legal currency of Mexico, a sum covering the total payment of annuities due from Mexico, namely, the annual payment of $43,059.99, and that the Mexican government shall pay to the United States on 2 Feb. 1903 and every following year of the same date forever, an annual payment of $43,059.99. Consult Doyle, T. T., 'History of the Pious Fund of California' (San Francisco 1887).

PIOZZI, pĭ-ŏz'ĭ (Ital. pē-ŏt'sē), **Hester Lynch Salisbury,** English author: b. Bodvel, Carnarvonshire, Wales, 16 Jan. 1741; d. Clifton, Gloucestershire, 2 May 1821. In 1763 she was married to Henry Thrale, a wealthy brewer of Southwark, which borough he afterward represented in Parliament. In 1764 the Thrales made the acquaintance of Dr. Johnson, who lived much with them for more than 16 years and of whom she published 'Anecdotes' in 1786. Thrale dying in 1781, his widow married in 1784 Gabriel Piozzi, a Florentine music master, then resident in Bath. This alliance annoyed her friends and Johnson gave up her society. She accompanied her husband to Florence and while there contributed several poems to the *Florence Miscellany,* founded by the leaders of the Della Cruscan School, much ridiculed by Gifford. Among her writings are 'British Synonym, or an Attempt at regulating the Choice of Words in Familiar Conversation' (1794); 'Retrospection, or a Review of the most Striking Events and Characters of the last 1,800 Years' (1801). Consult 'Autobiography, Letters and Literary Remains' (1861); Seeley, 'Mrs. Thrale' (1891); Countess Cæsaresco, 'Glimpses of Ital-

ian Society in the 18th Century' (1892); Boswell, 'Life of Samuel Johnson' (1791).

PIP. See POULTRY.

PIPA. See SURINAM TOAD; AGLOSSA.

PIPE, a wine measure, usually containing very nearly 105 imperial or 126 wine gallons. Two pipes or 210 imperial gallons make a tun. In practice, however, the size of the pipe varies according to the kind of wine it contains. Thus, a pipe of port contains 138 wine gallons; of sherry, 130; of Madeira, 100, etc. The pipe of port is seldom accurately 138 gallons and it is customary to charge what the vessel actually contains.

PIPE, Manufacture of. Pipes are hollow cylinders made of various materials and used as conduits for liquids, air or gas. The material of construction varies according to the character of the substance to be conveyed, its availability in any particular locality and its relative cheapness. They may be divided into five general classes characterized by the materials of which they are made—metal, wood, earthenware, cement and rubber. Metal pipes are made of lead, block-tin, zinc, brass, copper, cast iron, wrought iron and steel. Lead pipes have been used from the earliest times. Up to the close of the 15th century, they were made of sheet lead bent around a metal core and welded or soldered along the horizontal joint. About the beginning of the 16th century, a casting method was invented by Robert Brooke, which was extensively employed in England up to the close of the 18th century, when it was superseded by the pressing and drawing methods in use at the present time. They are made in continuous length, by squeezing the molten metal through a die (a steel plate perforated with a hole containing a central core) by hydraulic pressure. Different sizes of pipes are produced by changing the dies, the cores of the dies determining the diameter of the bores. Sizes of pipes are designated according to the measurement of their internal diameters. Lead water-pipes range from three-eighths to five inches, while the waste pipes range from one and one-half to five inches. Lead pipes as small as one-sixteenth of an inch and as large as eight inches are made for various purposes. The high cost of lead and the great thickness of metal required to withstand high pressures practically prohibit the production of the larger sizes. Pipes of ductile metal, such as block-tin, brass and copper, are made by drawing methods. An ingot of metal is cast in cylindrical shape with a conical end and with a hole through its axis corresponding in size to the bore of the desired pipe. A mandrel (long iron rod) is thrust into the hole so that it projects slightly beyond the conical end. This end is then placed in a funnel-shaped hole drilled through a steel post fixed to the drawing table and gripped at the outer end by a pair of pincers at the end of a chain attached to the power machinery. The ingot together with the mandrel is then drawn through the hole, the former being thus extended uniformly over the latter in the form of a complete pipe. Unlike the pressure method, the metal is drawn cold and often requires annealing, as it hardens under the repeated drawings. Block-tin pipes are used in soda fountains and as conveyors of beer and chemicals. Copper pipes are used in distilleries, and when employed in chemical works are tin-plated within to protect them from corrosion. Brass is generally used for pipes exposed to great heat, such as the tubes of steam boilers, etc. Block-tin pipes range from three-eighths to two and one-half inches in diameter.

Varieties.—Spiral-riveted and spiral-welded pipes are made by winding thin iron plates spirally around a mandrel into tubular forms, and the overlapping edges riveted or welded together. They are made in standard lengths of 20 feet and range from 3 to 24 inches in diameter. The metal plates used range from .035 to .109 inch in thickness. They are capable of withstanding bursting pressures up to 1,330 pounds to the square inch.

The locking-bar pipes are made of two semicircular plates of metal joined together longitudinally by a channel bar of soft steel, the flanges of which are pressed into the edges of the plates until a tight joint is effected. The earliest forms of wood pipes were simply bored logs. Their first use as a continuous tube was the six-foot penstock built at Manchester, N. H., in 1874, by J. T. Fanning. The use of metal bands around wood-stave pipes was first suggested in 1880 and were first extensively used in Denver, Colo., in 1883. This particular kind of pipe is built in a trench. The staves are of different lengths, which allows continuous construction. They are bound together by light metal rods or bands provided with screw ends and nuts for tightening.

Clay Pipe.—Earthenware or terra-cotta pipes are represented by the various forms of drain tiles, designedly made porous or vitrified and with or without joint sockets, according to the purposes for which they are used. They were first made in England about the close of the 18th century and were mere cylinders of porous baked clay. In recent years their manufacture has attained the proportions of a great industry. They are produced by forcing prepared plastic clay through a die into the form of a continuous tube, which is subsequently cut up into shorter lengths and the joint sockets molded by a special machine. They are then baked in kilns by a very high temperature. The vitrified variety are glazed by the introduction of salt into the fire holes of the kilns while the pipes are being baked, so that the salt is volatilized and combines with the silica in the clay. They range from 1½ to 36 inches in diameter and from one to three feet in length. Pipes are also made of cement and concrete. They are usually molded in place by the use of a movable mold and core, which is shifted along the work or by stationary built-up molds, which are torn out after the cement has set. Wire nettings and iron rods are often inserted in the cement to give additional strength.

Bibliography.—Special articles may be found in the files of following named publications: *Engineering News,* New York; *Street Railway Review,* Chicago; *Journal Am. Soc. of Naval Engineers,* Washington; *Progressive Age,* New York; *Scientific American Engineering Record,* New York; *Engineer,* London; *Engineering,* London. Consult also Rjorling, P. R., 'Pipes and Tubes' (New York 1908); Sharp, John, 'Some Considerations Regarding Cast-Iron and Steel Pipes' (1914).

PIPE, Tobacco, a bowl and connecting-tube, made of baked clay, wood, stone or other material and used in smoking tobacco. The cheap pipes in common use are made of a fine-grained white plastic clay. Much finer and more expensive pipes are made of meerschaum, a somewhat plastic magnesian stone of a soft greasy feel. (See MEERSCHAUM). This material is found in several parts of Europe (in Moravia, Piedmont and the Crimea), but more abundantly and of finer quality in Asia Minor. Meerschaum pipe making is carried on to the greatest extent by the Germans, and Vienna may be said to be the centre of the manufacture. Sometimes the bowl alone (which is frequently artistically carved) is of meerschaum, the stem being of wood, the best sorts of which are got from the young stems of the Mahaleb cherry, grown near Vienna, the mock orange of Hungary and the jessamine sticks of Turkey. The stem, whether of the same material as the bowl or of wood, is usually provided with a mouth-piece of ivory, silver or amber, the last being preferred. Briar-root pipes, with the bowl and stem of one piece of wood, and provided with amber, ivory or bone mouth-pieces, are now very common; they have little or no advantage over the clay pipe except in being less liable to break. Many Germans prefer pipes with porcelain bowls, which are sometimes beautifully painted in the style of fine chinaware painting. The Eastern hookah, or Turkish pipe, is a pipe of great length, the bowl of which is set upon an air-tight vessel partially filled with water, and has a small tube which passes down into the water; the long flexible smoking-tube is inserted in the side of the vessel. By exhausting the air in the smoking-tube, the smoke is forced down through the water, and entering into the space above it passes into the stem, cooled and freed from some of the most acrid properties of the tobacco.

In the United States, Indian pipes have been in use from very remote periods. They are found in the ancient mounds of the West, together with other relics of an unknown race, elaborately carved in stone into fanciful shapes, often resembling various animals of the country. In northern New York they are frequently discovered in plowing the land. Some are of soapstone and others of baked clay. In the account of the discovery of the Hudson River by Robert Juet, mention is made of «red copper tobacco pipes and other things of copper, which the savages did wear about their necks.» In the Northwest Territory, upon the summit of the dividing range between the Saint Peter's and the Missouri rivers, and in the latitude of Saint Anthony's Falls, the Indians have long procured a peculiar variety of red steatite or soapstone, of which all the red stone pipes of that region are made. The locality is held in great reverence by the Indians, and they have strongly opposed any attempts of the whites to visit it. Catlin, however, succeeded in overcoming their scruples, and was shown the spot at the base of a long vertical wall of quartz, which lay in horizontal strata, the pipestone layers spreading under the adjoining prairie land of the ridge, whence it was obtained by digging a few feet in depth. He judged from the great extent of the excavations, and from the graves and ancient fortifications, that the place must have been frequented by different tribes of Indians for many centuries. The pipes made of this stone are heavy and usually of rather plain form, decorated by bands and ornaments of lead, which appear to have been run into depressions made to receive it and then smoothed down. The stems are long and curiously carved sticks of hardwood, sometimes flat, frequently ornamented with gaily colored feathers of birds and horse hair dyed of scarlet hue.

The manufacture of the more expensive pipes in the United States began about 1860. Previous to that time they were imported; but the ordinary clay pipe has been in use since 1820. The earliest manufacturer whose name is now recorded was Thomas Smith, tobacco-pipe maker, of the city of New York, in 1847. The high tariff during the Civil War stimulated manufacturing. This was commenced on the smallest possible scale by two or three enterprising German workmen, with neither machinery nor experience. The goods could not be compared with the European product, and they were almost as expensive, even with the high tariff paid on the imported articles. Trade itself previous to the Civil War was very small. Edward Hen, who before 1860 was almost the only importer of note, was known as the pipe man of the United States. His pipe business was less than $50,000 per year. William Demuth, a pupil of Edward Hen, began the making of pipes in 1861. The local manufacture has steadily developed and by 1904 the pipe industry in the United States was not only equal to that at the celebrated factories in Vienna, Ruhla and Saint Claude, but surpassed the latter in many respects. Many improvements and inventions have been made in America, which were later introduced into Europe. There are at present about 25 factories in the United States making tobacco pipes; they employ 2,382 work people, paying $2,412,522 in wages; and manufacture a gross product of $7,647,105 annually, of which about $2,500,000 is expended for materials. New York is the leading State in the industry, turning out more than half the entire product.

PIPE-CLAY. See CLAY.

PIPE-FISHES, small teleostomous fishes included in the order *Lophobranchii* (and with the sea-horses (q.v.) constituting the family *Syngnathidæ*. The gills are disposed in tufts on the branchial arches, the gill-cover is a simple plate and the gill-aperture of small size. The body is covered by bony plates arranged transversely, and in the pipe-fishes is very long and attenuated. No ventral fins exist, and the jaws are united to form a pipe or tube, bearing the small, toothless mouth at the tip.

A very curious and remarkable circumstance in connection with the pipe-fishes consists in the males of some species possessing a pouch-like fold, situated on the under side of the abdomen or tail, in which the eggs are contained after being extruded from the body of the females. And after the young fry are hatched they continue to reside within this pouch for a longer or shorter period, when the pouch opens and permits them to escape. No analogous structure is found in the female.

The family *Syngnathidæ* comprises about 15 genera and 150 species, all small fishes of warm seas, and most of them true pipe-fishes, which

differ from the sea-horses in the possession of a caudal fin, while in the latter the fin is absent and the tail prehensile. Several genera of pipefishes occur in American waters, the principal one being *Siphostoma,* with at least 25 North American and West Indian species. The common pipe-fish (*S. fuscum*) is the only species found on the coast of the New England and Middle States and is very common in shallow bays and estuaries, where it lives among the vegetation. In this and related species the egg-pouch is formed of a pair of longitudinal folds which extend along the greater part of the long tail. All of the pipe-fishes are feeble swimmers, the fins being very small and weak; and their manner of moving through the thick vegetation may be described as crawling rather than swimming. They make very interesting tenants of salt-water aquaria. In *Daryrhamphus* the egg-pouch is beneath the abdomen; while the males of the genus *Syngnathus* carry the eggs uncovered on the skin.

The name pipe-fish is also applied to the members of the genus *Fistularia,* or trumpet-fishes, included in the order *Hemibranchii.* The bones of the face are prolonged to form a tubular structure, at the extremity of which the mouth opens. The *Fistularia tabaccaria* of the Antilles, averaging about three feet in length, represents this genus and occurs not infrequently on our Atlantic Coast.

PIPELINES. Pipelines are used for the transportation of various liquids and gases under many circumstances, but their predominating use in the United States is for the cross-country transportation of petroleum, gasolene and natural gas.

A petroleum pipeline system consists of a trunk line or multiple lines from producing fields to refining centres or water terminals, with pumping-stations at suitable intervals to force the petroleum through the lines under pressure and field gathering lines through which the petroleum from individual producing properties is brought together at the initial pump station. Storage tanks for excess oil are also employed at the terminals and one or more of the pump stations, for the purpose of equalizing the movement of oil through the lines. Gasolene pipelines extend from refining centres to marketing centres or water terminals and no gathering lines are necessary. Natural gas pipeline systems are comprised of gathering lines and compressing stations and trunk lines from fields to the markets in cities and villages. Pipelines vary in size from two inches in diameter for the small gathering lines to 12 inches in diameter for the major petroleum trunk lines and to 26 inches in diameter for the principal natural gas pipelines.

The flow of the liquid or natural gas through pipelines is governed by valves and control devices which regulate the pressure and flow so as to draw from different sources of supply and to deliver to different terminals as desired. A load dispatcher, using a telephone or other communication system, which is an essential part of a large pipeline system, directs the manipulation of the control devices and pumping equipment in much the same way that a train dispatcher directs the movement of trains over a railroad.

Pipelines are laid along routes, selected by means of surface and aerial surveys, either along public roads and highways or on private rights-of-way purchased from land owners. The pipelines, with minor exceptions, are buried to a depth which avoids interference with farming or other uses of the surface of the land and which provides protection against accidental breakage, and the mechanical difficulties which would arise from the expansion and contraction under the wide temperature changes to which lines laid on the surface would be subjected.

Pipeline construction is an outstanding example of the mechanization and technologic advance that has affected industry in recent years. Surveys for pipeline routes are now made with the aid of aerial photography. A single truck or tractor hauls more pipe and distributes it more rapidly along the right-of-way than dozens of teams and wagons could do a few years ago. Ditches were formerly dug by men with picks and shovels. Now a ditching machine with two operators can accomplish as much work in the same time as the hundred or more men of the old-time ditching gang. The handling of the pipe in the process of uniting the lengths either by coupling or welding and laying it in the ditch is done by truck-mounted booms and pipe-laying machines with a few men replacing a crew of about 75 men. Tractor-drawn scrapers, instead of men with shovels, «back-fill» the ditch after the pipe is laid. Pipeline operation and maintenance today with the aid of wired communications along the entire right-of-way, radio, trucks, tractors, portable water-pumping units and other mechanized equipment is also in contrast to the early methods of operation when quick communication to all points along the right-of-way was lacking during floods, landslides and other emergencies and transport was by means of draft animals.

Pipelines have been principally constructed with pipes made of cast iron, wrought iron and steel by a variety of processes. Cast iron pipe and butt-welded and lap-welded wrought iron pipe were first available followed by butt-welded and lap-welded steel pipe. The next development was seamless steel pipe and this was followed by the development of electrically welded steel pipe. All of these are still being installed but seamless and electrically welded steel pipe is principally used while the other types are employed under special circumstances.

The pipes used in constructing pipelines have been connected or joined by several different methods. Bell and spigot, flanged and screw coupling joints were among those used in the early pipelines. The use of rubber-packed sleeve type couplers was next introduced in natural gas pipeline construction followed by the now widely used process of welding together of pipes by the oxy-acetylene or electric-arc methods for both petroleum and natural gas pipelines. These various methods of joining pipes are used either singly or in certain combinations in present pipeline construction.

One of the principal problems in pipeline construction and maintenance is to prevent or retard the corrosion of the pipeline material. Chemical and physical tests of soils and studies of drainage, electrolytic, galvanic and other conditions are conducted in order to ascertain the kind and location of protective coating which will be most useful and to determine the necessity and most suitable method of cathodic pro-

tection. Numerous pipe coating materials have been developed for either hot or cold application. Cathodic protection consists of creating an electrical potential in the soil which is higher than that of the pipeline and thus, by making the line electrically negative to the surrounding medium, preventing or minimizing the destructive effect of electrical currents flowing from the pipe into the soil.

Pipeline transportation of petroleum in large volumes can be accomplished at lower costs than by other methods of land transportation. Large quantities of petroleum and its products are moved in railway tank cars, and in tank wagons and tank trucks, but it would be impractical to provide enough of such facilities to take care of the enormous movement of crude petroleum and its products which the relative locations of producing fields and refining and marketing centres make necessary. Where the quantity to be moved between a source of supply and a market is sufficient to justify a pipeline, the cost of carrying is reduced, on the average, to almost one-half of that of transportation in railway tank cars. Shipment by tank steamers and barges can be accomplished at lesser costs than by land transportation and the petroleum pipeline systems have, therefore, been developed with the dual purpose of providing inland refining and marketing centres with crude petroleum and petroleum products and of also carrying these commodities to water terminals so that advantage can be taken of tank ship or barge transportation for the remainder of the haul to refineries and markets. One of the important features of pipeline transportation is that it does not require a movement of empty tanks or vessels from the delivery point to the source as is necessary in other modes of transportation.

The idea of transporting petroleum in pipelines was suggested as early as 1860. In 1863 the first successful oil line was constructed in western Pennsylvania. This was an iron pipeline two inches in diameter and two and one-half miles in length extending from several oil wells to a small refinery. In 1878 a line was laid from the oil fields in northwestern Pennsylvania to the Atlantic seaboard. The expansion of the petroleum-producing area into Indiana and Illinois about 1890 and into Kansas, Oklahoma and Texas in the period from 1900 to 1910 was accompanied by extension of existing pipeline systems and the building of new ones to connect the new fields with the refining centres already established on the northern Atlantic seaboard, and with ports on the Gulf Coast as well as with inland refineries. The development of petroleum fields in California was accompanied by the building of pipelines to the coast where the larger refineries are located. The Wyoming fields are connected to the pipelines in the central and eastern States.

The latest complete survey (United States Bureau of Mines, 1936) of the pipelines of the United States reported a total of 115,038 miles of petroleum pipelines. The petroleum production of the United States has averaged about 1,000,000,000 barrels per year since 1929, nearly all of which has been transported varying distances through oil pipelines. The gasolene trunk lines, the first of which was built in 1929, carried 85,297,000 barrels in 1938, mostly from refineries in Texas and Oklahoma to marketing centres around the Great Lakes.

By far the greatest part of the petroleum pipelines of the world are in the United States. There are many lines between wells and refineries or seaports in the other petroleum producing countries but most of them are comparatively short. The longer lines furnish outlets to marine terminals for the petroleum fields of Russia, Iraq and Colombia.

The early recorded history of the transportion of natural gas begins with the use of bamboo pipes in China where over a thousand years ago gas was transported for evaporating salt brine and domestic purposes. Other instances of the transportation of natural gas in various parts of the world occur in the historical records of the industry; however, the first commercial use of natural gas in the United States was recorded in 1825 at Fredonia, New York where the gas was handled through small lead pipes. The next construction of a natural gas pipeline of historical interest in the United States was the wooden pipeline 12.5 inches outside diameter and eight inches inside diameter and 25 miles in length constructed in 1870 to Rochester, New York. In 1872 the first long iron pipeline was laid, being two inches in diameter and five and one-half miles long in the vicinity of Titusville, Pennsylvania. The industry developed slowly for several years with the use of natural gas restricted largely to industries in the immediate vicinity of producing wells and supplied through pipelines built by the producers or industrial users. Between 1872 and 1890 corporations were organized to transport and sell natural gas to customers in the industrial communities of Pennsylvania, West Virginia, Ohio and New York. These latter lines did not exceed about eight inches in diameter, were constructed of wrought iron pipe joined with screw couplings and operated at about 80 pounds per square inch pressure. The long distance high pressure transportation of natural gas may be considered to have begun with the construction in 1891 of two parallel eight-inch pipelines operating at an initial pressure of 525 pounds per square inch and extending a distance of 120 miles from natural gas fields in northern Indiana to Chicago, Illinois.

Following 1900 there was an expansion of the natural gas pipeline systems in the Appalachian area and by 1910 the greater part of western Pennsylvania, northern West Virginia and Ohio were supplied with pipelines extending from the Pennsylvania, West Virginia and Ohio fields. During this same period and principally after 1912 a number of large natural gas pipeline systems were developed in Oklahoma, Texas, Arkansas, Louisiana, Missouri and Kansas. There grew up in all of these states vast networks of gas gathering and transportation lines handling gas produced within a few hundred miles of the place of consumption.

The discovery and development of the enormous natural gas reserves in such fields as the Monroe field in northern Louisiana, the Amarillo field in the Texas Panhandle and the Hugoton field in southwestern Kansas and the Oklahoma Panhandle made possible in 1926 and the next few years the construction of pipelines of greater size and length than had previously been undertaken. Fourteen major pipelines ranging in size from 18 to 24 inches in diameter

were constructed by 1931 from these fields to distant centres of population such as Chicago, Kansas City, Denver, Memphis, New Orleans, St. Louis, Atlanta, Birmingham, Houston, Dallas, Omaha and Minneapolis and further construction in 1936 extended one of these lines to Detroit. One of the outstanding examples of these long distance pipelines is the 24-inch line from the Amarillo field to the Chicago area built in 1931 in accordance with the most advanced engineering principles across six States and traversing a distance of 1,000 miles between the producing area and the principal cities where the gas is used for all fuel purposes.

The development of natural gas production in California was accompanied by the construction of large networks of gas gathering and major transporation lines in the southern part of the State and in 1929 and 1930 of the construction of major pipelines 20 to 26 inches in diameter from the Kettleman Hills, Buttonwillow and other fields to the San Francisco Bay region.

While the principal known natural gas deposits in this country occur in 20 States this fuel is made available through natural gas pipelines to the important communities of 34 States where at the present time over 1,400 billion cubic feet of natural gas is used annually for all fuel purposes by over 9 million customers and a population in excess of 42 million people in over 5,150 communities. To effect the transportation of this gas from the producing fields to the places of consumption pipeline systems including compressing stations with 900,000 installed horsepower and over 85,000 miles of pipeline are employed exclusive of the over 90,000 miles of local mains used in distributing the gas after its transportation is completed.

President and Director, Cities Service Company; President and Director, Natural Gas Pipe-Line Company of America, etc.

PIPER, The. Josephine Preston Peabody's 'The Piper' won a prize offered in competition by the English actor, F. R. Benson, for the best poetic drama. It had previously been submitted to the New Theatre, New York, but had been rejected. The interest created by its production at the Memorial Theatre, Stratford-upon-Avon, by the Benson Company, on 26 July 1910, warranted a reconsideration of the play by Mr. Winthrop Ames, with the result that it was given a colorful première at the New Theatre, on 30 Jan. 1911, Miss Edith Wynne Matthison in the rôle of The Piper. It was hailed by the American critics as the precursor of a poetic revival on the stage. But thus far (1919) the American theatre has been pledged to the drama of condition, of psychology, rather than of poetry. And Miss Peabody's 'The Piper' stands better known as a reading drama than as a piece of the theatre. Judged as poetry, its story is clothed in a symbolism which makes the old legend of The Pied Piper of Hamelin take on a significant modern application. Judged as drama, its pictorial effectiveness is hampered by the infusion of social and Christian ethics, which are not as fully developed as they should have been. To Miss Peabody, The Piper represents the singing, free side of life, whereas Hamelin and its stodgy population are measure of the selfish, money-grubbing side of daily existence. The old Piper of Browning's poem and of the German folktale was simply a rat exterminator of prodigious merit. Miss Peabody's Piper is the enchanter of childhood, and by his playing he would free them of Hamelin, which is inimical to the child spirit. His is not the compassionate love of Christ for little children, but it has the same lyric charm. The Lonely Man of the Cross who fascinates the crippled Jan, and his mother—the only Mother of Hamelin who goes forth in the right spirit to seek her child whom the Piper has lured away—are the spiritual threads on which the philosophy of the play is strung. This philosophy, slim though it be, has poetic beauty and universal applicableness. In a sensual way Ibsen's the Rat Wife in 'Little Eyolf' is recalled by the Piper legend. And the ethics of the play seem to be this; that in all the Hamelins of this world, there are parents whose worldly vision separates them from a joyful life lived with their children. To preserve this life, the Piper, at the close of the play, goes onward, piping his lure of childhood until Christ's love for little children enters all our hearts.

Miss Peabody (Mrs. Lionel Marks) studied dramaturgy under Prof. G. P. Baker, at Harvard, and was for a time instructor of English at Wellesley College. In addition to 'The Piper,' she has written the following dramas: 'Marlowe' (1901); 'The Wings' (1905); 'The Wolf of Gubbio' (1913). Consult 'The Diary and Letters of Josephine Preston Peabody, edited by Christina H. Baker (1925); 'The Collected Plays of Josephine Preston Peabody, with Foreword by George P. Baker (1927).

Montrose J. Moses.

PIPERAZINE, Diethylene diamine $NH\langle\begin{matrix}CH_2.CH_2\\CH_2.CH_2\end{matrix}\rangle NH$, is obtained, mixed with a number of basic substances, by the interaction of ammonia and ethylene bromide or ethylene chloride. The crude product is purified by treatment with nitrous acid, which forms a nitroso derivative; the latter will readily yield piperazine by the action of a reducing agent.

The manufacture of piperazine on a commercial scale involves the following steps: (1) The formation of diethylene diphenyl diamine by treating ethylene bromide with aniline and anhydrous sodium carbonate; (2) the conversion of this compound into a nitroso derivative by the action of sodium nitrate in the presence of hydrochloric acid; (3) the liberation of piperazine from the nitroso derivative by first treating it with sodium bisulphite and then with sodium hydroxide.

Piperazine is a crystalline hygroscopic compound having a melting point of 104°–107° C. and a boiling point of 140°–145° C. It readily dissolves in water, absorbs carbon dioxide from the air with great avidity and shows strongly basic properties forming crystalline salts with inorganic and organic acids. Of special interest is the salt which it forms with uric acid converting it into a soluble compound. This property of piperazine has made it a popular remedy for diseases caused by the accumulation of uric acid in the body. Piperazine has therefore been recommended as an efficient cure for gout, rheumatism, uric acid gravel and calculi. Piperazine is especially valuable as a remedy for these diseases since it passes through the system without any toxic action. A number of piperazine derivatives have also been recommended as solvents for uric acid; of these, piperazine quinate or Sidonal, dimethyl piperazine tartrate or Lysetol, and dihydroxy piperazine are well-known examples.

V. S. Babasinian.

PIPERINE, PIPERIDINE, PIPERIC ACID and PIPERONAL. Piperine, pĭp′-ẽr-ēn, the chief alkaloid (5–9 per cent) of the fruit of black pepper, *Piper nigrum,* and other *Piper* species, discovered by Oersted in 1819. Chemically it is piperoylpiperidide, $C_{17}H_{19}NO_3$, an amide of piperic acid with piperidine. It crystallizes from alcohol in monoclinic needles melting at 128–129.5° C., optically inactive, slightly soluble in water. It is a weak base, but forms salts with strong acids. It has a sharp taste but is without marked physiological action. When hydrolyzed with alkali it yields piperic acid, $C_{12}H_{10}O_4$, (white crystals, melting point 217° C., insoluble in water), and piperidine (hexahydropyridine), $C_5H_{11}N$, a colorless liquid having an odor of pepper and of ammonia, solidifying at —9° C., boiling at 106° C., strong base readily soluble in water. Piperonal, $C_{12}H_{10}O_3$, is the aldehyde corresponding to piperic acid; colorless crystals with heliotrope odor, melting point 37° C., used in perfume; it occurs in *Robinia pseudoacacia.* See also Alkaloids.

PIPESTONE, Minn., city and Pipestone County seat; alt. 1,725 feet; 197m SW of Minneapolis; on the Milwaukee; Rock Island; Chicago and North Western; and Great Northern railroads. The county is agricultural; the city has creameries. The courthouse and the library building are of red granite quarried near by. There are also deposits of the soft red Indian pipestone. The city has a recreation park, with equipped playgrounds and a swimming pool. South of the city lies the Mound Springs State Park area, and Blue Mound a massive bluff of quartzite, approximately three miles long. Settled in 1878, Pipestone received its city charter in 1901. Pop. (1940) 4,682.

PIPEWORT, an acaulescent, or very short-stemmed bog or aquatic plant, with tufted grass-like basal leaves and very small flowers in terminal solitary heads on long, slender, hollow, ribbed scapes. Many species exist in the family *Eriocaulaceæ.*

PIPING CROW, a bird (*Gymnorhina tibicen*) of New South Wales, remarkable for its musical powers and for its ability in mimicking the voices of other birds and uttering a few parrot-like words. It is black and white in color and is allied to the shrikes.

PIPIRI, pē-pē′rē, a West Indian name for the large tyrant flycatchers known in the United States as kingbirds, especially *Tyrannus dominicensis.*

PIPISTRELLE, one of the smallest and most familiar of European bats (*Vespertilo ripistrella*).

PIPIT. See Titlark.

PIPPA PASSES. This brief but delightful poetic drama by Browning was published as the initial number of 'Bells and Pomegranates' in 1841, and, according to Mr. Gosse, was the first work of its author to win the public. Mrs. Orr says that it was conceived when the poet was once walking in a wood near Dulwich. There came to his mind the image of some one, unimportant in himself and unconscious of his influence upon others, walking alone through life and yet influencing permanently the lives of those whom he met. The image took shape in the person of one of Browning's most charming imaginative creations, Felippa, or «Pippa,» the little Italian girl of Asolo, near Venice, who on her one holiday of the year passes singing through the streets and by her songs changes the lives of the other persons of the play. The time of 'Pippa Passes' is the early 19th century, the «local color» that of Asolo, but the story has no historic foundation. The play consists of prologue and epilogue spoken by Pippa in her room; of four principal scenes, which take place respectively in the morning, noon, evening, and night of Pippa's holiday; and by three interludes on the streets. The form is free lyric verse in Pippa's monologues and songs, blank-verse in the first, second and third scenes, and prose in the fourth scene and the interludes. Pippa, wishing to make the most of her holiday, alone, yet longing to love and be loved, identifies herself with those whom she fancies must be the happiest in Asolo—with Ottima and Sebald, the guilty lovers in the great house on the hill; with Luigi and his loving mother; with Jules the sculptor and Phene his bride; and with Monsignor the Bishop, who loves but God. As Pippa passes in turn by the houses of these persons, her song greets each at a crisis of his life. Ottima and Sebald are spiritually saved; Jules, about to send away the ignorant and base-born Phene, whom he has been tricked into marrying, lifts her instead up to his own level and into his heart; Luigi, about to yield to his mother's plea that he give up his dangerous patriotic mission, chooses death rather than safety; and Monsignor the Bishop, tempted to sin through avarice, turns upon his tempter and saves his soul.

Pippa's songs are not impressive in themselves; their power and significance lie only in the hearer's state of mind, but they change the course of destiny; for "all service ranks the same with God," with whom "there is no last nor first." Each of the four scenes, complete in itself, is essentially and intensely dramatic; the characters are all individualized, though their speech is rather the speech of Browning; the style is always appropriate and at times, with its intensity of feeling and magnificence of imagery, rises to the heights of very great poetry. The scenes are given background and continuity by the interludes in the streets, in which figures artists, village girls, and the Austrian police. Pippa has no personal concern in the action save in the last scene, in which by her singing she unconsciously saves herself from death or worse. The human truth underlying the conception of the play, the dramatic force of the various scenes, the representative characterization and the always forceful and often superb style, combine to render 'Pippa Passes' one of the very few remarkable poetic dramas in recent English literature, almost the only one, in fact, that has gained a large reading public and yet has qualities that fit it for the stage. Although not written for the theatre, it has repeatedly been presented in special performances with all the fine effect to be expected from its essential dramatic quality. Rolfe's 'Select Poems' contains 'Pippa Passes' with introduction and notes, and Miss Burt discusses the character of Pippa in her 'Browning's Women'.

MARION TUCKER.

PIPPAL, an Indian tree. See PEEPUL.

PIPPI, pĭp pē, Giulio. See GIULIO ROMANO.

PIPPIN, the name given to a certain class of desert apples, probably because the trees were raised from the pips or seeds, and bore the apples which gave them celebrity without grafting. They seem to have been introduced into Great Britain from France, and were little known there until about the end of the 16th century. In the time of Shakespeare pippins were delicacies for the dessert: Sir Hugh Evans, in the 'Merry Wives of Windsor,' says: "I will make an end of my dinner — there 's pippins and cheese to come." Justice Shallow, in his invitation to Falstaff, says: "You shall see mine orchard, where, in an arbour, we will eat a last year's pippin of my own grafting." The ribston, golden, Newton, and the small Scoth oslin or arbroath pippin are favorite sorts. See APPLE.

PIPSISSEWA, a plant, prince's pine (q.v.).

PIQUA, pik'wą or -wā, Ohio, city in Miami County, 899 feet above sea level, on the Miami River and the Pennsylvania and Baltimore and Ohio railroads; 73 miles west of Columbus. It is at the intersection of two major federal highways. The chief manufactured products are knit underwear, woolen felts and blankets, walnut veneer and other wood products, motor ambulances, and oil machinery. Settlement was first made here in 1797. Fort Piqua here was the scene of fighting in the French and Indian War and a supply base in the War of 1812. The city is governed by a commission which chooses the mayor and city manager. There is a city planning and zoning committee. Pop. (1940) 16,049.

PIQUÉ (pē-kā') **WORK,** an old form of decoration consisting of a pattern made up of small lozenge-shaped units: made in fabrics with a needle or in hard surfaces by inlaying.

PIQUET, pē-kā', a game of cards played between two persons with 32 cards, all the plain cards below seven being thrown aside. On the cards being shuffled the players cut for deal; the party drawing the lowest card has to deal first. The cards are then dealt two by two until each player has 12 cards, the eight remaining undealt (called the stock) are laid on the table between the players. The first hand (the non-dealer) must then discard five or less of his cards (he must discard at least one), exchanging them for an equal number drawn from the stock; the younger hand (the dealer) may exchange from the stock three or less, but may refuse to exchange altogether. In playing, the cards rank in order as follows: the ace (which counts 11), the king, queen and knave (each of which counts 10) and the playing cards each of which counts according to the number of its pips. The player who first reaches 100 has the game. The score is made up by reckoning in the following manner: Carte blanche, the point, the sequence, the quatorze, the cards and the capot. Carte blanche is a hand of 12 plain cards, and counts 10 for the player who holds it. The point is the suit of highest value, the value being determined by the number it makes up when the cards held are added together; thus, if a player holds ace, king, ten, nine and eight, his point would be 48. The first player having called a point, the younger hand must then say whether his point is superior, equal or inferior in value to his opponent's, by calling in the first place "good," in the second "equal," and in the last "not good." If the elder hand's point is "good" he at once shows it, and counts one for each card in it, except with the points 34, 44, 54 and 64, which count one less than the number of cards. If the points are equal he counts nothing. The sequence is composed of a regular succession of cards in one suit, and the highest sequence. The quatorze is composed of four aces, four kings, four queens, four knaves or four tens, and counts 14. The winner of the greatest number of tricks counts 10 in addition (the "cards"), if he holds all the tricks he counts 40 in addition (the "capot"). For the sake of convenience the scores are generally recorded at the end of the hand; but they are recordable no matter by which hand they are made, according to the following table of precedence: 1, carte blanche; 2, point; 3, sequences; 4, quatorzes and trios; 5, points made in play; and 6, the cards. If one player scores 100 before the other obtains 50 he wins a double. Consult Cady, 'Piquet' (1896).

PIRACICABA, pē-rä-sē-kä'bä, Brazil, a town of the state of São Paulo, on the Piracicaba, headstream of the Tieté affluent of the Parana River, about 122 miles northwest of São Paulo with which and Rio de Janeiro, 270 miles eastward, it is connected by rail. It has an active export trade in the cotton, coffee and sugar of the surrounding region. Pop. 25,374.

PIRACY. See PIRATE.

PIRACY IN STREAMS. See STREAM PIRACY.

PIRÆUS, pī-rē'fs, Greece, the port of the city of Athens, lying five miles southeast of the city and now terminus of railroads to Athens and to the Morea. Three excellent harbors indent the shore deeply, Piræus, Zea and Munychia. Munychia is also the name of the mountainous peninsula separating the harbor from the Saronic Gulf, and on this peninsula is the town, which was built 493 B.C. by Themistocles, whose able policy of Athenian defense soon effected the construction of the famous "long walls." These made Athens independent of the rest of Attica, as was plainly seen in the Peloponnesian War, when, with the additional walls built by Cimon and Pericles, Athens was undisturbed, although all Attica outside of the walls was in the hands of the Peloponnesians. But the destruction of the remains of the Athenian navy at Ægospotami in 404 B.C. left the port defenseless; it was taken and the walls were destroyed to the music of the flute. Conon rebuilt them 10 years later, and Athens temporarily regained some of its importance. But the splendid city, one of the master works of the Periclean age, was finally destroyed by Sulla in 86 B.C., and there was only a wretched village on its site even some years after 1836, when Athens again became the capital of Greece. But in 1835 the old name had been revived, to take the place of Porto Leone, the name given by the Italians. The present city is modern in its construction; has street railways, a gymnasium, exchanges and theatres; is the principal port in Greece, now outranking Syra; manufactures macaroni, cheese, cognac, liquors and various textiles; has a large import and a moderate export trade; and is the main station of the Greek transatlantic line, and of various steamship lines, so that it is in direct connection with Trieste, Corfu, Istanbul, Smyrna, Alexandria and Marseilles. About 3,800 steamships of 2,500,000 tons enter at this port yearly, two-thirds of this tonnage flying the Greek flag. There are several consulates. The population of the city is estimated as about 328,300. Consult Weller, C. H., 'Athens and Its Monuments' (New York 1913).

PIRAI, pĭ-rī, or **PIRAYA**, pĭ-rā'yä (*Serrasalmo piraya*), voracious fresh-water fish of the caribe family of tropical America. It is three or four feet in length and its jaws are armed with sharp lancet-shaped teeth, by which cattle when fording rivers sometimes suffer terribly. So sharp-edged are the teeth that they are mounted and used as knives by the Indians of Guiana, for pointing their blow-pipe arrows, etc. See CARIBE.

PIRANESI, Giovanni Battista, jō-vän'nē bät-tēs'tä pē-rä-nā'zē, Italian architect and engraver; b. Venice, 4 Oct. 1720; d. Rome, 9 Nov. 1778. He passed the greater part of his life at Rome. He published 'Antichita Romane' (1756); 'Antichita d'Albano e di Castel Gandolfo'; 'Trofei d'Ottaviano Augusto'; 'Della Magnificenza ed Architettura de' Romani,' and over 100 views of modern Rome. His architectural designs display much grandeur and fertility; but his representations of real objects are not always faithful. His son and pupil, Francesco, continued the publication of works on similar lines.

PIRATE, one who sails the seas for the purpose of robbery, whether in command of a ship or as one of the crew; a highwayman of the sea; a freebooter, or buccaneer. Piracy is the term applied to the crime of robbery committed upon the high seas. It is an offense against the universal law of society. As the pirate has renounced all the benefits of society and government and has reduced himself to the savage state of nature, by declaring war against all mankind, all mankind must declare war against him; so that every community has a right, by the rule of self-defense, to inflict that punishment upon him which every individual would, in a state of nature, otherwise have been entitled to do for any invasion of his person or personal property. By various statutes in England and the United States other offenses are made piracy. Thus, if a subject of either of these nations commits any act of hostility against a fellow-subject on the high seas, under color of a commission from any foreign power, this is an act of piracy. So, if any captain of any vessel, or mariner, run away with the vessel, or the cargo, or yield them up to a pirate voluntarily, or of any seaman lay violent hands on his commander, to hinder him from fighting in defense of the ship or goods committed to his charge or make a revolt in the ship, these offenses are acts of piracy by the laws of England. By statute of George II the ransoming of any neutral vessel, which has been taken as a prize, by the commander of a private ship of war, is declared to be piracy. By the act of Parliament, passed in 1824, the slave-trade is also declared to be piracy. In the time of Richard I, all infidels were regarded as pirates and their property was liable to seizure wherever found. By the law of nations the taking of goods by piracy does not divest the actual owner of the property. Piracy, with intent to murder, stab or wound, is capital and pirates can gain no rights by conquest. It is of no importance, for the purpose of giving jurisdiction in cases of piracy, on whom or where a piratical offense is committed. A pirate, who is one by the law of nations, may be tried and punished in any country where he may be found; for he is reputed to be out of the protection of all laws. But if the statute of any government declares an offense, committed on board one of its own vessels, to be piracy, such an offense will be punished exclusively by the nation which passes the statute. In England the offense was formerly cognizable only by the admiralty courts, which proceeded without a jury, in a method founded upon the civil law. In the United States piracy is tried in the Federal courts.

Piracy, in the common sense of the word, is distinguished from privateering by the circumstance that the pirate sails without any commission and under no national flag and attacks the subjects of all nations alike; the privateer acts under a commission from a belligerent power, which authorizes him to attack, plunder and destroy the vessels which he may encounter belonging to the hostile state. He is not regarded as a pirate by the laws of nations, but in accordance with these is bound to observe certain rules and restrictions. Thus, he is debarred from attacking the vessels of the enemy while lying in any port or haven under the protection of a friendly or neutral state. It was held by many experts in international

law that the U-boats of Germany, though commissioned by their governments, were engaged in piracy whenever they attacked neutral vessels. See NEUTRALITY.

PIRATE BUG, a predaceous bug of the family *Reduviidæ*. See CONE-NOSE.

PIRATES OF PENZANCE, The, a comic opera by William S. Gilbert and Sir Arthur Sullivan, which was produced 31 Dec. 1879 in New York City and in London on 3 April 1880.

PIRENE, pī-rē′nē, a spring of crystal water at Corinth, which in Greek tradition was sacred to the Muses.

PIRITHOUS, pī-rĭth′ō-ŭs (Gr. *Peirithoos*), in Grecian mythology, a son of Zeus and Dia, the wife of Ixion; he was king of the Lapithæ. At the marriage of Pirithous with Dejanira, Eurythion, one of the Centaurs, attempted to do violence to the bride and thence resulted the famous battle of the Centaurs and Lapithæ. After the death of Dejanira (also named Hippodamia) Pirithous with his trusty friend Theseus carried off Helen from Sparta. At Athens it was decided by lot which was to have her and Theseus won; but under the conditions of the lot the winner must help his comrade to procure a wife and Pirithous' choice of a wife was Proserpine, wife of Pluto. To the infernal kingdom, therefore, the two heroes went down, but suddenly were powerless to stir from the seats they had taken. Afterward Hercules delivered Theseus, but Pirithous remained in Hades for evermore, loaded with 300 chains.

PIROGUE, pĭ-rōg′, or **PERIAGUA,** pĕr-ĭ-ä′gwą, the name given a small canoe used on the Western rivers of the United States and in Central and South America. It is commonly cut from a single log and is popularly known as a dug-out. In the West Indies a larger boat deckless, but with two masts, bears the name.

PIRON, pē-rôń, **Alexis,** French wit, poet, and dramatist: b. Dijon, 9 July 1689; d. Paris, 21 Jan. 1773. He studied law at Besançon and later went to Paris, where he produced in 1738 his *chef d'œuvre,* 'Metromanie,' a comedy which Laharpe characterizes as excelling in plot, style, humor and vivacity almost every other composition of the kind. In the latter part of his life he made repeated attempts to gain admission into the French Academy, but without success. He revenged himself for his disappointment by calling the Academy *Les invalides du bel esprit,* and composing the humorous epitaph:

> "Ci-gît Piron, qui ne fut rien,
> Pas même académicien."
>
> "Here lies Piron, who was nothing —
> Not even an Academician."

There is a collective edition of his works by Juvigny (1776). Troubat published 'Œuvres Choisies de Piron' in 1890.

PISA, pē′zä or -sä, Italy, a province of Tuscany and its capital city. (1) The province of Pisa, bounded on the north by Lucca, on the east by Florence and Siena, on the south by Grosseto, and on the west by Livorno and the Ligurian Sea, has hills in the south and east, notably the Monti Pisani and the Monti di Volterra, and at the west a fertile plain, watered by the Arno and Serchio, and rich in vines and olive orchards. Its mineral wealth is marble, alabaster and mineral waters; and its industries cotton and silk spinning. Its area is 942 square miles and its population at present is about 375,000, of which 334,224 are in the district of Pisa, the others living in the second district of the province, Volterra. (2) The capital of the province, situated on both banks of the Arno, about seven miles from its mouth, is on the railroads between Genoa and Rome and between Florence and Livorno, and is the terminus of a line running from Pistoja through Lucca. The streets are old and crooked, but well paved and broad, and lined with substantial dwellings, many built of marble. The modern city is on the south side of the Arno and contains one old building of importance, the Gothic church of Santa Maria della Spina, on the Lungarno, that is, the street "along the Arno," which is peculiarly picturesque on either side of the river. In the old city to the north are the cathedral, built of dazzling white marble in 1063 to commemorate a naval victory near Palermo, with a façade formed of four galleries of pillars, bronze doors designed by John of Bologna, and within five naves separated by Greek and Roman columns, the spoil of various Pisan victories, and 12 lateral altars attributed to Michelangelo, but probably the work of Stagi di Pietra Santa; the Baptistery, begun in 1153 and finished in 1278, a great dome-crowned rotunda 190 feet high, in which are a fountain executed by Guido Bigarelli in 1246, and a chair supported by seven columns and decorated in fine bas-relief by Nicolas Pisano (1260); the Campanile or Bell Tower, better known as the leaning tower of Pisa, begun in 1174 by Bonanno, and finished in 1350, with its eight stories of pillars, a total height of 179 feet and a deviation from the perpendicular of over 16½ feet in 1910; and the Campo Santo, originally a cemetery filled in with earth from the Holy Land at the close of the 12th century, and between 1278 and 1283 surrounded by Giovanni Pisano with a rectangular portico more than 400 feet long and 170 feet wide, decorated on the outside with frescoes by Florentine and Siennese artists of the 14th and 15th century, notably the 23 scenes from the Old Testament by Benozzo Gozzoli and the 'Triumph of Death' and 'Last Judgment' by the two Lorenzetti; on the inside are funereal monuments of different periods. There are many other buildings of beauty in the city, mostly churches; mention should be made of the Palazzo Medici on the Lungarno, built in 1027 and enlarged three centuries later, of the University with an early Renaissance court, and of the Palazzo Lanfreducci, built (1590) of Carrara marble.

The industry and commerce of the city are slight, but it has cotton factories, machine shops, glass and hat factories, and also produces alabaster. The city is a favorite winter resort because of its mild and delightful climate. It has rail connections as noted above and steamboat lines to Marina and Pontedera. It is the seat of an archbishop, of a civil and a military governor, and of a court of the first resort. Its educational equipment includes the University, founded in 1338, closed in 1359, revived in 1364 only to die out again in 1406, and newly established in 1473 by Lorenzo, and in 1542 by Cosimo de Medici, and again in 1838 by Leopold II of Tuscany, and at present made up of facul-

ties of law, philosophy, medicine and surgery and mathematics and natural science, with 1,200 students at present; related to the University are normal, engineering, pharmaceutical, veterinarian and agricultural schools, a museum of natural history, founded in 1596, and particularly rich in Tuscan ornithology and geology, and a botanical garden, as well as a library of over 200,000 volumes, excluding pamphlets; and there are also secondary schools, technical and industrial schools, a valuable library in the archiepiscopal seminary, a Museo Civico, and archives with documents dating back to the city's relations with Frederick Barbarossa and Richard I of England.

Pisa was one of the 12 cities of the Etruscan confederation, became a Roman colony 180 B.C., and in the 9th and 10th centuries took a prominent place in Italy. In the 11th century its power was extended to Sardinia and Corsica (1050), it defeated the Saracens (1063) off Palermo, and took part in the first crusade. About 1100 its population was estimated at 150,000. The city sided with the Ghibellines and suffered severely when the Guelfs were victorious. The long feud with Genoa, came to an end with the Pisan defeat in 1283 at Leghorn, and in 1300 Sardinia, Corsica and the Belearic Islands were evacuated. Twenty-five years later Aragon got control of Pisa, which changed owners several times in the next three quarters of a century, and in 1406 was sold to Florence. In 1409 the Council of Pisa (q.v.) met (25 March). Pisa rebelled against Florence in 1494, fought bravely for 15 years, and were finally reduced by starvation. As an appanage of Florence it became a part of the grand-duchy of Tuscany, and thus entered the Italian kingdom in 1860. Consult Rohault de Fleury, 'Les Monuments de Pise au Moyen Age' (1866, with atlas); Schubring, 'Pisa' (1902); Valtancoli-Montazio, 'Annali di Pisa' (1845); Langer, 'Politische Geschichte Genuas und Pisas im 12 Jahrhundert' (1882). Pop. of commune (1928) 77,105.

PISA, Council of, an assembly of bishops and theologians generally but not universally accounted by Catholic divines to be œcumenical. It was called by leading cardinals belonging to the two "obediences" into which the Church was at the time divided, the "obedience" of Gregory XII, canonically elected in 1406, and that of Benedict XIII (Peter de Luna), anti-pope since 1395; and its purpose was to end the schism. The two rivals promised to withdraw their claims and to abdicate, so that then a pope might be elected with undisputed title. But the promises were not kept. The council met 25 March 1409, and was dissolved 7 August. The number of bishops who attended in person or by deputy was 200, of cardinals 20, of abbots near 300. When the rival popes refused to submit their claims to the council's judgment, the cause of each was weighed, and both of them were declared deposed, and the election of a new pope demanded of the college of cardinals. The cardinals elected Cardinal Philargi, who took the name of Alexander V. But as Benedict and Gregory persisted in their claims the situation was only made worse, and the schism, which already had for 30 years divided the Church, continued eight years longer, till it was ended by the action of the Council of Constance. Previously, in 1133, there was a council at Pisa, which condemned Peter de Bruys. Again in 1511 a council was called then to condemn Pope Julius II, but the cardinals refused.

PISACAS, pē-shä'käs, in Hindu mythology, certain base and cruel demons, who devour human flesh; they are practically ghouls, embodying the spirit of lying, adultery and lunacy. Agni, the pure spirit of fire, is implored to drive them away, and by certain incantations these malignant spirits can be induced to cure diseases and perform other beneficent offices. According to early tradition they were produced by creative power from the drops of water which were scattered, in superfluous profusion at the creation of beneficent beings — gods, men, etc., or as the children of Prajapati, or of one of the Prajapatis.

PISAGUA, pē-sä'gwä, Chile, a port of the province of Tarapaca, on the Pacific Coast, 40 miles by rail north of Iquique. On 18 April 1879 the city was bombarded and destroyed by the Chileans; and near the town, 19 Nov. 1879, occurred a battle in which the combined forces of Peru and Bolivia, numbering about 11,000, were defeated by a Chilean force of 6,000. Pisagua ships large quantities of nitre brought from the interior. It has a foreign commerce totaling about $8,000,000 annually. Pop. about 2,800.

PISANITE, a mineral consisting of sulphate of iron and copper (Fe Cu) $So_4.7H_2O$. Common in old drifts at Butte, Montana, and in Old Jordan mine, Bingham, Utah.

PISANO, pē-zä'nō, a surname or appellation of several artists of Pisa, distinguished in the early history of Italian art; among them are: (1) Giunta Pisano, or G. di Pisa, also styled Giunta di Giustino: the earliest known Pisan painter (about 1190–1250). He is supposed to have been a pupil of the Byzantine painters who came to Pisa after the capture of Constantinople by the Venetians, and to him belongs the credit of reviving the art of painting in Italy. (2) Niccola Pisano (about 1200–1275), eminent alike in sculpture and architecture, the greatest artist of the 13th century, and one of the restorers of the ancient classic sculpture, getting his inspiration from the sculpture of an ancient sarcophagus brought from Greece. Three works typical of his style are extant, namely, the pulpit in the baptistery of Pisa, the shrine of Saint Dominic at Bologna and the pulpit of the Siena Cathedral. (3) Giovanni Pisano (about 1235–1320), son of Niccola, an artist hardly inferior to his father as sculptor or architect. His most celebrated works are the Campo Santo of Pisa, the magnificent high altar and reredos in the cathedral of Arezzo, the splendid façade of the cathedral of Siena, and the church of Saint Dominic at Perguia, the north transept of which contains his beautiful tomb of Benedict XI. The little chapel of Santa Maria della Spina at Pisa was the most beautiful of his architectural works; but it has been spoiled by "restoration."

PISANO, Vittore, commonly known as PISANELLO, Italian painter and medalist: b. San Virgilio, on Lake Garda, 1380; d. 1456. He exercised his art in Verona, Venice, Pavia, Rome, Ferrara, Rimini, Milan, Mantua, and Naples.

Several of his paintings are still to be seen in Verona and among them an 'Annunciation' in the church of San Fermo and a 'Saint George' in that of Santa Anastasia. These pictures are in fresco. His principal fame, however, comes from the fact that he was one of the first artists to model portraits and cast them in metal medals. His works are prized as among the most excellent historical memorials of his time.

PISANUS, pĭ-sā'nŭs, **Leonardus** (Leonardo di Pisa), Italian mathematician of the 13th century: b. Pisa, about 1160. His father, called Bonaccio (probably a nickname), was in the employ of the merchants of Pisa, who had establishments for trade on the southern and eastern coasts of the Mediterranean, and Leonardo, whose nickname in his boyhood was Bigollone (dunce), was destined by his father to be a clerk or accountant in one of the factories. To fit him for this station he was sent to the town of Bugia in Algeria, a noted emporium at that time, resorted to by the European and Arab merchants. Later, in his travels round the Mediterranean, he so improved his opportunities as to acquire an extraordinary fund of erudition. Returning to Italy in 1202 he published his 'Liber Abaci,' in which are set forth the most perfect methods of arithmetical calculation. It is a voluminous treatise, occupying 459 pages in the printed edition of the author's works; and deals arithmetically and algebraically with the most difficult and complex problems. He had mastered the geometry of Euclid and the algebra of Mohammed ibn Musa. Besides the 'Liber Abaci,' he wrote 'Practica Geometriæ'; 'Liber Quadratorum'; and some minor works which discuss advanced mathematical problems.

PISCATAQUA, pĭs-kăt'ą-kwą, a river on the boundary between Maine and New Hampshire. It has its rise in East Pond, between the towns of Newfield, Maine and Wakefield, N. H. The upper part of its course is called Salmon Falls River. After passing Dover, N. H., it is connected with a tidal lake, and then flows past Portsmouth to the Atlantic. From Portsmouth to the sea — three miles — there is but little obstruction by ice — the strong tide preventing. The harbor is one of the best in the United States. The entire river is about 82 miles long.

PISCES, pĭs'ēz, that group of animals called fishes; the term has been variously limited with varying views of affinity and classification. See Fish; Ichthyology.

PISCES, *in astronomy,* a sign of the zodiac, which is entered by the sun about 19 February. The constellation which occupies the zodiacal region corresponding to the sign has the same name; it contains some interesting double stars.

PISCICULTURE. See Fish Culture.

PISCINA, pĭ-sī'ną, in Roman antiquities, a large water basin or pool, often one in which fish were kept. In ecclesiastical architecture, the stone basin used to receive the water after it has been used for washing the chalice, subsequent to the eucharistic celebration. The piscina is supplied with a drain-pipe to carry the water out of the church, and is usually constructed in the southern wall of the sanctuary. It sometimes takes the form of a canopied niche decorated with carving.

PISCO, pēs'kō, Peru, a city and port of the department of Ica, on the bay of Pisco, where the Chunchanga River empties into it. A railroad connects it with the inland cities of the department. It exports cotton, sugar, silver, wine, salt, and spirits; and has ginning and oil factories. Pop. about 5,000.

PISEMSKI, pē'sĕm-skē, **Alexei Feofilaktovitch,** Russian novelist: b. Ramene, Kostroma, Russia, 20 March 1820; d. Moscow, January 1881. He was educated in the University of Moscow and was for some years engaged in government service, resigning in order to devote himself wholly to literary pursuits. His work, which belongs to the realistic school, is of a most sombre and cynical type, betraying an entire lack of high ideals and a failure to recognize anything noble or good in humanity. His most successful novel, 'A Thousand Souls,' was published in 1858, and much of his work has been translated into German and French. Among his books are 'Boyarshchina' (1847); 'A Bitter Lot' (1853); 'The Stormy Sea' (1863); 'In the Whirlpool' (1871). His complete works were issued in 24 volumes in 1895.

PISGAH, a mountain in Transjordania, in the Abarim Range, east of the Dead Sea. The name seems at times to have been applied to the whole range, and again limited to one of the summits. It is supposed to be identical with Mount Nebo (q.v.) 2,643 feet. It is not the highest peak of the range, but the one nearest to the place were the Israelites were encamped. From the summit may be seen (to the west) Samaria, Lower Galilee, as far as Tabor, and the chain of Gilboa. To the southwest may be seen the north half of the Dead Sea, the precipices of Engedi, and beyond, the desert of Judea.

PISISTRATUS, pĭ-sĭs'trą-tus, a notable Greek "tyrant" of Athens: d. about 527 B.C. He first appears as an educated well-to-do citizen of Athens, of most engaging manners and strong ambitions. He held a minor office at the time there were three parties in Greece: the party of the Plain, comprising the landed proprietors, then headed by Lycurgus; that of the Coast, or wealthy trading class, headed by Megacles; and that of the Highlands, mainly made up of the laboring population. The latter being the party that seemed most likely to further his designs, Pisistratus threw in his lot with it, and secured its allegiance by coming forward as patron and benefactor of the poor. In all his public speeches he was the advocate of civil equality and a democratic constitution. On one occasion he appeared in the marketplace with several slight self-inflicted wounds, and called upon his fellow-citizens to protect him against certain alleged enemies, who had, as he said, attacked his life on account of his adherence to the democracy. A bodyguard of 50 men was voted him; this force he soon greatly increased, and made himself popular with his guard and bound them to serve him, and in 560 B.C. seized upon the acropolis. He was now master, or, as the Greeks termed it, "tyrant" of the city. The term was equivalent to the modern political "boss." Solon had long recognized him as a dangerous man and a hypo-

crite, but his charges had been unheeded, and Solon departed from his enslaved country. But though a tyrant in the Greek sense, his use of power was by no means tyrannical. He was twice in exile, once for five years, once for 11, but regained his power. He forced many of the idle inhabitants to leave the city and cultivate the country around, which by these means was covered with corn-fields and olive plantations. Those who had no resources of their own he supplied with cattle and seed. He extracted from everyone the tenth part of his income and earnings, and thus increased the revenue of the state, which he expended in splendid public buildings. He established a public library, and collected and arranged the poems of Homer. Twice was he deposed and driven away, and twice he returned and assumed authority. The last time he came back with an army of Greek mercenaries whom he had attached to himself by developing some gold mines at Mount Pangæus, and spending the sums gained with great liberality. When he returned, about the year 540, thousands of his old supporters rallied about him, and he ruled from that date until his death, with great wisdom, and care to maintain his popularity. He kept the people at work, reduced the taxes of the agriculturists, improved the courts of law, and increased the prosperity of the state. He carried out many of the reforms proposed by Solon, whom he had virtually thrust out of office. As he well knew how tyranny was hated he carefully concealed his power under the exterior of a private citizen. He submitted like others to the jurisdiction of the Areopagus, before which he was accused of murder, and conducted himself with as much prudence as clemency. Consult the works by Flach (1885) and Töpffer (1886).

PISO, pī'sō, **Gaius Calpurnius,** Roman politician of the 1st century B.C. Cicero speaks very favorably of him as an orator. He became consul with Manius Acilius Glabrio in 67 B.C., and in 66–65 B.C. was proconsular administrator of Narbonese Gaul. Accused of extortion by Cæsar, he was defended by Cicero, whom he urged, to accomplish his own revenge, to bring charges against Cæsar as one of the Catilinarian conspirators.

PISO, Gnæus Calpurnius, Roman politician of the late 1st century B.C. and early 1st century A.D. He was consul with Tiberius (q.v.) in 7 B.C. and when the latter became emperor was employed to thwart Germanicus (q.v.) in all ways possible, to which end he received the command of Syria. It was thought at the time that he caused the death of Germanicus by poison. Tiberius was forced to sanction an investigation by the Senate; but before its termination Piso was found dead, whether by suicide or sacrificed by Tiberius to arrest popular indignation is uncertain.

PISO, Lucius Calpurnius, with agnomen **Frugi,** Roman statesman and historian of the 2d century B.C. He was tribune of the plebes in 149 B.C. and consul (with Publius Mucius Scævola) in 133 B.C. He opposed the corn laws, especially the *lex frumentaria,* of Gaius Gracchus. He wrote several orations and the 'Annales,' a history of Rome from the earliest period to his own time, none of which has survived

PISO, Lucius Calpurnius, Roman politician of the 1st century B.C. and father-in-law of Julius Cæsar. The most of our information regarding him is obtained through Cicero, who depicts him in the darkest of colors. Inasmuch as the great orator was both a personal and a political enemy, some reasonable modifications of his estimate must be made. As consul in 58 B.C. (with Aulus Gabinius), he obtained Cicero's banishment (see CICERO) and in 57–55 B.C. as governor of Macedonia he certainly plundered the province most rapaciously. On returning from exile Cicero spoke his mind about him in the speeches 'De Provinciis Consularibus' and 'In Pisonem.' See CÆSAR.

PISO, Marcus Pupius, Roman orator and politician of the 1st century B.C. He held the prætorship at an uncertain date, was proconsular administrator of Spain and on his return thence in 69 B.C. received a triumph. In 61 B.C. he was consul (with Marcus Valerius Messalla Niger). In his earlier period an excellent forensic speaker and better versed than his predecessors in Greek literature, he was an instructor of Cicero.

PISOLITE, or **PEASTONE,** aggregated concretions, usually calcareous, about the size of peas. Upon being split open these globules show a concentric structure. They are sometimes made up of considerable beds of pisolitic limestone, which is particularly characteristic of certain parts of the Jurassic system.

PISSARO, pē-sä-rō, **Camille,** French artist: b. Saint Thomas, West Indies, 10 July 1830; d. Eragny, 12 Nov. 1903. He studied art under Melbye and Corot and his early work showed the influence of the latter. In choice of subject he is allied with Millet, though he does not invest his scenes of rustic life with the same pathos. In the luminous quality of light he surpassed Millet. This predilection for effects of light predisposed him to favor the departure of the so-called "impressionists" and about 1870 he allied himself with the group composed of Manet, Degas, Renoir, Claude Monet and a few others. After much ridicule the new departure won the day as a recognized method of technique. Though popular in France Pissaro's pictures are not so well known outside that country. Seven of his works hang in the Luxembourg. Special exhibitions were held at intervals in Paris after 1890. Views of Rouen, Paris and the country about Eragny besides studies made in London during a visit with Monet form his later subjects.

PISTACIA, a genus of trees of the family *Anacardiaceæ.* The 10 or a dozen species are natives of western Asia and the Mediterranean region, with one in Mexico. They have alternate, evergreen or deciduous leaves; small, apetalous, dicœcious flowers in axillary racemes or panicles; and dry, drupaceous fruits with bony stones which split in two and expose the oily kernels. The pistacia — or pistachio — nut or tree (*P. vera*) is a native of western Asia but is cultivated in the Mediterranean region and other warm climates, including California. It grows about 20 feet tall, bears pinnate leaves and fruits about as large as olives. The kernels, known also as green almonds, are widely used for flavoring and coloring confectionery, ices, cakes, etc. The turpentine tree (*P. terebinthus*) yields Cyprian or Scio turpentine, a greenish-

yellow, fragrant product which has been used by druggists and physicians since the days of Hippocrates. It is a native of the Mediterranean region, attains heights of about 30 feet and has pleasant oily fruits. It is cultivated to a small extent in the southern and southwestern United States. The batoum tree (*P. atalantica*), a native of northern Africa, grows about 40 feet tall, bears an edible fruit popularly used by the Arabs and an aromatic gum resin which is chewed as a dentifrice and breath perfume. The lentisk or mastic tree (*P. lentiscus*) yields mastic (q.v.), a gum resin, and the kernels of *P. oleosa* yield a fragrant oil used by the Orientals for perfuming ointments and other druggists' compounds. The tree is indigenous to eastern Asia.

PISTIL, *in botany,* the female organ of a phanerogamous flower, occupying almost invariably the centre of the flower. See FLOWER.

PISTOIA, pĭs-tō'yä, or **PISTOJA** (ancient PISTORIA), Italy, city in the province of Florence, about 20 miles northwest of the city of Florence. The city is noted for its fine specimens of early art and architecture. Verrocchio's first work in marble is said to be the monument to Cardinal Forteguerra, in the cathedral. The cathedral was built in the 12th century. A pulpit by Pisano is in the church of Saint Andrea. Other remarkable art productions are here; the ancient churches and palaces are well preserved and of great historic and artistic interest. In 62 B.C. Catiline was defeated here, and the name of the place occurs frequently in the history of the contentions between the Guelfs and Ghibellines. It is said to have received its name on account of firearms having been first made here. It has considerable manufactures of silk goods, firearms, glass, paper, iron and steel wares, linen and woolen goods. Pop. of commune about 63,000; town, 14,000.

PISTOL. See SMALL-ARMS.

PISTOLE, pĭs-tōl', a gold coin formerly in use in Spain, Italy, Switzerland and some parts of Germany. It was originally a Spanish coin and was equivalent to $3.65. One of the Italian pistoles is quoted as worth $5.55.

PISTON, in engines and motors, a device for reciprocating in a cylinder or tube, and receiving pressure from a fluid or gas, or delivering pressure. It is usually cylindrical or drum-shaped, so fitted as to fill the sectional area of a tube, such as a pump barrel, or the cylinder of a motor, and capable of being driven alternately in opposite directions, by the pressure of a motive fluid, or of being reciprocated by a crank and connecting rod, and thus compressing any gas confined in the cylinder. A piston requires to fit snugly in its tube or cylinder, and the usual device for fitting it tightly is called "packing," but consists of a series of spring spiral rings that by their expansive tension fill the cylinder bore very accurately. A piston and cylinder with connecting rod and crank constitutes a mechanical motion fundamental in the building of reciprocating engines and motors. See CYLINDER; STEAM AND STEAM ENGINES; MOTOR; LOCOMOTIVE, THE.

The piston of a rotary pump takes a radically different form from the standard piston. It is really a swinging sector, called a piston, because it performs the work of a piston. It is usually a rectangular plate, arranged to rock on a centre, and fill the cross section of a sector, in which it moves and forces the containing fluid.

PIT AND GALLOWS, a term now obsolete, formerly, in feudal times, a privilege granted to barons by the Crown, in virtue of which they were empowered to hang on a gallows men convicted of theft or other crimes, and to drown in a pit or well women guilty of those crimes.

PIT-RIVER INDIANS, the name given several small American tribes of the Palaihnihan family residing along the Pit River in northeastern California. The river received its name from the tribal custom of digging deep pits or windfalls for capturing deer and other animals. These Indians are of a very inferior type, mentally and physically, and were formerly very warlike and hostile. About 1,000 of them roam about the Pit River region refusing to reside on the Indian reservations.

PIT VILLAGES, collections of earth caves, dug in the ground and covered with stones, wood, clay or sods of turf. They were used by prehistoric races or by races of the lowest stages of barbarism. A good example was unearthed during the latter half of the 19th century near Andover, in Hampshire, England. The pits are reached by entrance shafts, sloping downward. The pits themselves are oval or pear-shaped, varying between 22 and 42 feet in length, and are about 12 or 13 feet wide and five feet high, with the fire-place in the centre. Flint and bone implements and rude pottery have been found in them.

PIT-VIPER, a venomous viperine snake of the family *Crotalidæ* or subfamily *Crotalinæ,* prominently represented by the rattlesnakes, and characterized by a deep pit between the eye and the nostril, the function of which, if it has any, is not known. See VIPERS; RATTLESNAKE.

PITA. See FIBRE.

PITAKA, pĭt'ą-ką, in the sacred literature of the Buddhists, any one of *tripit'aka* meaning the three great divisions of canonical works, which, and collectively, constitute the whole Buddhistic code. The *Sutta-Pittaka* embodies the philosophy and traditions of the Buddhists. There are five books and 15 parts. The *Vinaya-Pitaka* deals with discipline and includes five books; the *Abhidhamma-Pitaka,* of seven books, discourses of metaphysics, the elements, manifestation, and enumerates personal duties.

PITAVAL, John Baptist, American R. C. archbishop: b. France, 10 Feb. 1858; d. 23 May 1928. His preliminary studies for the priesthood were made in the archdiocese of Lyons, France. In June 1881 he came to the United States and entered Saint Mary's Seminary, Baltimore, being ordained a priest by Rt. Rev. Joseph P. Marchebeuf in Denver, Colo., 24 Dec. 1881. For 21 years he devoted himself to missionary work in Colorado and on 25 July 1902 was consecrated titular bishop of Sora and auxiliary bishop of Santa Fé. When this see became vacant on the death of Archbishop Bourgade in May 1908, Bishop Pitaval was named administrator of the archdiocese of Santa Fé, which office he filled with eminent success, being

made archbishop, 3 Jan. 1909. He resigned in 1918, becoming titular archbishop of Amida.

PITCAIRN, pit'kārn, **John,** Scotch soldier: b. Fifeshire, about 1740; d. Boston, Mass., 17 June 1775. He seems to have been a soldier from his youth; was promoted to be captain of marines in 1765 and to be major in 1771; was stationed in Boston about 1772; and was popular there because of his just treatment of complaining colonists. He led the advance guard of the force sent from Boston to Concord 19 April 1775, met the minute men at Lexington, ordered them to disperse, and took part in the resulting battle, which is commonly believed to have been begun by his orders to fire, though his own story was that the minute men fired first. Pitcairn played a prominent part in the battle of Bunker Hill, was the first to mount the breastworks and was mortally wounded by a negro as he was crying "Now for the glory of the marines."

PITCAIRN, Pa., borough in Allegheny County; alt. 1,020 feet; 15m. SE. of Pittsburgh; on the Pennsylvania Railroad. In a coal mining region, Pitcairn has railroad shops; other industries are the making of brick and manufacture of electrical goods. Laid out in 1890, incorporated in 1894, the borough has government by mayor and council. Pop. (1930) 6,317; (1940) 6,310.

PITCAIRN ISLAND, a British possession in the Polynesian Islands, belonging to the Low Archipelago, in lat. 25° 5′ S.; long. 130° 5′ W., about two miles long and one mile wide. Its coast is almost perpendicular and is fringed with rocks and reefs, making it impossible to land except at a few points. The island was discovered by Carteret in the year 1767 but remained uninhabited until 1790 when nine British sailors, mutineers of the ship *Bounty*—then under the command of William Bligh—landed on the island, together with a group of 18 natives, 6 men and 12 women, brought from Tahiti. Following their arrival came a number of murders and various crimes. After 10 years John Adams (q.v.) and a few survivors were left. His reform and his manner of teaching and supervising the little colony led to a complete change. They became peaceable, moral and industrious. He had saved a Bible from the ship and ruled his little kingdom with wisdom and justice. An American sealing ship visited Pitcairn in 1808 and H. M. S. *Britain* in 1815. The British Crown took formal possession in 1839. In 1856 the community (194 in number) was removed to Norfolk Island, Pitcairn having become too small for their comfortable subsistence. Some of the number, about 40, returned to Pitcairn. In 1936 (latest figures) there were on the island 209 persons, including adult males, adult females, and children. In religion the islanders are Seventh Day Adventists. A recent colonial office report describes the people as having degenerated from their former manner of living. The products of the island are sweet potatoes, beans, sugarcane, yams, taro, melons, oranges, bananas, pineapples and arrowroot. Excellent coffee also grows. There are on the island about 200 wild goats and a small stock of chickens. The local government is administered by a council of five members, with a president, who acts also as chief magistrate, and a vice-president, who is also government secretary, subject to the control of the high commissioner for the western Pacific. See BLIGH, WILLIAM.

PITCH, a thick, sticky, dark, resinous substance with brilliant lustre, obtained from the various kinds of tar produced in the destructive distillation of wood, coal, etc. Pitch is extensively used in ship-building, etc., for closing up seams, also for keeping wood from speedy decay, or iron railings from rusting when exposed to the weather. Natural pitch, as that found in the noted pitch lake in Trinidad, is formed of the dried flow of petroleum. The residue of petroleum in refining also yields tar, and in gas making tar is formed as a by-product. Pitch and tar are chemically the same, but the term pitch is used mainly for the product from the southern pines and natural deposits in pitch lakes. See TAR.

PITCH, *in mechanics,* inclination, slope; *in architecture,* the rise, or versed sine of an arch; *in carpentry,* the inclination of a roof.

The point or degree of elevation is also termed pitch. Musical sounds give to the mind a feeling of acuteness or gravity according to the rapidity or slowness of the vibrations producing them; hence, the former are called acute or high, the latter grave or low. See MUSIC.

PITCH AND HITCH, a game for ten players, five on a side, usually played indoors. Disks of galvanized metal are pitched from a distance of ten yards into a receiver, a round rubber dish, having an opening at the top five inches in diameter. The game is similar to that of quoits (q.v.), the courts being the same.

PITCH LAKE. See TRINIDAD.

PITCH AND TOSS, a game played by throwing up a coin and calling heads or tails; hence, to play pitch and toss with anything is to be careless or wasteful about it; to play ducks and drakes.

PITCHBLENDE. See URANINITE.

PITCHER, Moll, American heroine. She was the wife of a soldier in the Continental army and at the battle of Monmouth, 28 June 1778, saw her husband killed in the act of firing a cannon. She at once took his place, fired the already loaded cannon, and fought throughout the day. She was praised by Washington who commissioned her a sergeant in the army.

PITCHER, Thomas Gamble, American soldier: b. Rockport, Ind., 23 Oct. 1824; d. Fort Bayard, N. Mex., 21 Oct. 1895. He was graduated from West Point in 1845, served in the Mexican War and for gallantry at Contreras and Churubusco was in 1847 brevetted 1st lieutenant. He served on the frontier until the outbreak of the Civil War, defended Harper's Ferry in 1862 and later served in the Virginia campaign. From 1863–65 he was provost-general-marshal, and in the latter year brevetted brigadier-general in the regular army for services throughout the war. He was mustered out of the volunteer service in 1866 and commissioned colonel of the 44th Infantry. In 1866–71 he was superintendent at West Point, governor of the Soldiers' Home near Washington in 1871–77, and in 1880–87 superin-

tended the New York Soldiers and Sailors' Home.

PITCHER, Zina, American physician: b. Washington County, N. Y., 1797; d. 1872. In 1822 he was graduated at Middlebury College and soon afterward was appointed assistant surgeon in the army. In 1835 he was president of the Army Medical Board. After 15 years, connection with the army medical service, he resigned and established a medical practice in Detroit. He was thrice mayor of Detroit; was president of the Michigan Medical Society in 1855–56 and of the American Medical Association in 1856. He also served as regent of the University of Detroit. He was also for three years editor of the *Peninsular Medical Journal.*

PITCHER-PLANTS, plants whose leaves resemble pitchers. These pitchers, which are more or less filled with water, are thought to act as plant-food gatherers, especially of nitrogenous food, which they are believed to digest from the bodies of entrapped insects. Generally they have lids whose office is to keep out rain; honey-secreting glands, which attract insects; downward pointing hairs or bristles which permit the visitors to crawl down in the pitchers but prevent their return; digestive and even pepsin or enzyme-containing secretions which act upon the soft parts of the insects' bodies. After the nectar-hunting insects have finally begun to decompose, the odor of decay frequently attracts carrion-feeding insects so the plants may be said to have two harvests.

Mosquitoes have been known to breed in the water contained in the pitchers.

The best-known kinds are the species *Nepenthes* (family *Nepenthaceæ,* of which about 50 tropical species, mostly Malayan, have been described. These are the pitcher-plants seen in greenhouses, the pitcher pendant upon the ends of rather narrow leaves. Two genera of these plants are American. The pitcher-plants or "side-saddle flowers" of the swamps east of the Rocky Mountains, especially well-known east of the Mississippi River, belong to the genus *Sarracencia.* The other genus has only one species (*Darlingtonia californica*), which is found only at high elevations of the Pacific Coast. *Heliamphora nutans* is a unique species found in northern South America. These three genera constitute the family *Sarraceniaceæ. Cephalotus follicularis* is an Australian plant with pitchers resembling those of *Nepenthes,* but it belongs to a different family.

PITCHSTONE, a glassy volcanic rock, assumed to resemble hardened pitch, but of any color. It is translucent on thin edges and breaks with a conchoidal or splintery fracture. It occurs in the form of dikes and as lava-flows and may be considered as a natural glass formed by the rapid cooling of those lavas of which common feldspar (orthoclase) forms a considerable part. Sometimes it is spherulitic, the spherules, which are occasionally of large size, showing a fibro-radial structure. It is found chiefly in Mexico, South America and southern Europe.

PITH, the cylindrical or angular column of cellular tissue at or near the centre of the stem of a plant, also called the medulla, of which a good example is afforded by studying Chinese rice paper, made from the pith of the *Aralia papyrifera.* The pith is at first succulent and of a greenish color, afterward it becomes dry, and in many plants its cells are broken up, leaving large cavities. In its primary state it appears to be a reservoir of nourishment for the embryo plant. See PLANTS, STRUCTURE OF.

PITHECANTHROPUS ERECTUS, (erect ape-man), the name given by Dr. Eugene Dubois to the fossilized remains found by him in Java in 1891–92. These consist of the upper part of a cranium, a left femur and two molar teeth, and indicate a high order of ape, closer to man than any previously noted of Pleistocene ages. Much doubt and discussion was aroused at first in regard to it but the weight of scientific opinion is now that it was either an ape or a man, or that the bones became mixed, hence that there is no "missing link". The animal when erect must have stood 5½ feet high, "and the contents of the cranium," says Beddard, "must have been 1,000 cm., that is to say 400 cm. more than the cranial capacity of any anthropoid ape, and quite as great or a trifle greater than the cranial capacity of some female Australians and Veddahs; but as these latter are not five feet in height, the ape-like man had really a less capacious cerebral cavity." The skull in form and capacity stands roughly midway between that of a young chimpanzee (with no crest), and that of the lowest human example known — the man of Neanderthal. Consult the discoverer's monograph, 'Pithecanthropus erectus' (Batavia 1894, in German); reprinted in English in 'Smithsonian Report' for 1898; Haeckel and Gadow, 'The Last Link' (1898); and Beddard, 'Mammalia' (1901).

PITHOM, pī'thŏm, a town of northern Egypt, in the land of Goshen, built for Rameses II by the children of Israel (Exod. i, 11), as a storage city to supply his Asiatic armies. The town was discovered at Tell el Maschulah, between Ismailia and Tell el Kebir in 1882, and its ruins explored by Dr. Naville (1882–83). A statue of Rameses II was unearthed as well as of other monarchs of up to the 22d dynasty to the time of the Ptolemies. Consult Naville, 'The Store-city of Egypt and the Route of the Exodus' (1888).

PITKIN, Timothy, American lawyer and historian: b. Farmington, Conn., 21 Jan. 1766; d. New Haven, Conn., 18 Dec. 1847. He was graduated at Yale in 1785; became a lawyer and a leader of the Connecticut Federalists, who elected him to Congress in 1805; served there for 14 years; and was one of the earliest political historians of the United States. He wrote 'Statistical View of Commerce of the United States of America' (1816), and 'Political and Civil History of the United States of America from the Year 1763 to the Close of Washington's Administration' (1828).

PITMAN, Benn, American phonographer: b. Trowbridge, Wiltshire, 24 July 1822; d. Cincinnati, Ohio, 28 Dec. 1910. He was educated in the academy of his brother, Sir Isaac Pitman (q.v.), and for 10 years engaged in lecturing on and teaching phonography in England. In 1853 he came to this country and established the Phonographic Institute at Cincinnati, Ohio, of which he was long president. His latter teaching differed in several particulars from

that of his brother. He was military recorder of State trials during the Civil War, invented the electro-process of relief engraving, and in 1873–92 was lecturer on art and teacher of artistic wood-engraving in the Cincinnati Art Academy. He published 'Manual of Phonography' (1854); 'History of Shorthand' (1858); 'A Plea for American Decorative Art' (1895); 'Phonographic Dictionary' (1899).

PITMAN, Sir **Isaac,** English phonographer: b. Trowbridge, Wiltshire, 4 Jan. 1813; d. 22 Jan. 1897. He was educated in London at the Normal College of the British and Foreign School Society, and in 1832 was appointed master of the British school at Barton-on-Humber. In 1837 he published 'Stenographic Sound-Hand' which under the present title of phonography or stenography has become so widely used as to practically extinguish the earlier systems. It is claimed that he first suggested the postage stamp as a convenient way of paying postage. The *Phonographic Journal,* afterward named the *Phonetic Journal,* was established by Pitman in 1842, and he edited it for over 50 years. His 'Shorthand Instructor' found extensive use in commercial and high schools. He published numerous 'manuals,' and over 200 works in shorthand, ranging from the Bible to the 'Vicar of Wakefield,' etc. He was knighted by Queen Victoria for his «eminent services to stenography.» Consult his «Life,» by Benn Pitman. See also Shorthand.

PITMAN, N. J., borough in Gloucester County; alt. 130 feet; 16m. S. of Camden; on the Pennsylvania-Reading Seashore Lines. Located in farm and orchard country near large cities, Pitman is nonindustrial, a residential borough. Here a summer campmeeting is held annually. Pitman has government by mayor and council. Pop. (1930) 5,411; (1940) 5,507.

PITNEY, Mahlon, American jurist: b. Morristown, N. J., 5 Feb. 1858; d. Washington, D. C., 9 Dec. 1924. In 1879 he was graduated at Princeton University and in 1882 was admitted to the bar. From 1895 to 1899 Mr. Pitney was a member of Congress and in 1899–1901 was a member of the senate of New Jersey. In 1901–08 he was associate justice of the Supreme Court; in 1908–12 he was chancellor. In the latter year Justice Pitney was elevated to the Supreme Court of the United States in succession to Justice Harlan. He allied himself with the conservative group of the Supreme Court.

PITRI, in Hindu mythology, one of several orders of divine or spiritual beings. According to one of the Vedic accounts the older manes or deceased ancestors of mankind were pitris, and a great deal is written about the Lunar pitris. The tar prajapatis are also alluded to as pitris; they were creators of the human race, and included ancestors of demons. For a full understanding of the term consult Besant, A., 'Ancient Wisdom' (1892); Sinnett, 'Esoteric Buddhism' (1883).

PITT, William, English Parliamentary orator and statesman: b. Hayes, near Bromley, Kent, 28 May 1759; d. Putney, 23 Jan. 1806. He was the son of the Earl of Chatham (q.v.). In 1773 he entered Pembroke Hall, Cambridge, where his knowledge of mathematics and the classics seems to have astonished ripe scholars. His acquaintance with modern literature was slight. Of living languages besides his own he was almost entirely ignorant; an imperfect knowledge of French was all he possessed. His whole education was directed to the end of making him a great Parliamentary orator. In 1778 he entered Lincoln's Inn, and in 1780 was called to the bar. He attended the western circuit once and was introduced into Parliament by Sir James Lowther, as representative for his borough of Appleby. His maiden speech was delivered in support of Burke's financial reform bill. On the failure of Fox's India bill, which produced his dismissal of the North and Fox coalition ministry, Pitt, although at that time only in his 24th year, assumed the station of Prime Minister by accepting the posts of First Lord of the Treasury and Chancellor of the Exchequer. Although strongly supported by the sovereign, he stood opposed to a large majority of the House of Commons, and with the exception of Henry Dundas (q.v.), every other prominent debater in the House was against him. In spite of many defeats in the Commons he refused to dissolve Parliament or resign, until, having at last obtained a majority, he fixed the day (24 March 1784) on which the king dissolved Parliament.

At the general election which followed the voice of the nation appeared decidedly in his favor, and some of the strongest interests in the country were defeated, Pitt himself being returned by the University of Cambridge. His first measure was the passing of his India bill, establishing the board of control, followed by much of that fiscal and financial regulation that gave so much *éclat* to the early period of his administration. The establishment of the delusive scheme of a sinking fund followed in 1786. In 1788 Pitt resisted the doctrine of the opposition that the regency, during the king's indisposition, devolved upon the Prince of Wales by right. The minister maintained that it lay in the two remaining branches of the legislature to fill up the office, but that the prince could not be passed over in nominating to this post. By the adoption of this principle he was enabled to pass a bill restricting the regent's power, which the king's recovery rendered unnecessary. The French Revolution now broke out, and in 1793 war arose between Great Britain and France. Great Britain was successful by sea, but during the life of Pitt the conflict on the Continent was in favor of France. In 1800 the Irish union was accomplished. In 1801 the opposition of the king to all further concessions to the Irish Catholics caused Pitt to resign his post. The Peace of Amiens succeeded; and the Addington administration, which concluded it, Pitt supported for a time, and then joined the opposition. The new minister, who had renewed the war, unable to maintain his ground, resigned; and in 1804 Pitt resumed his post at the Treasury. Returning to power as a war minister, he exerted all his energy to render the contest successful, and found means to engage the two great military powers of Russia and Austria as well as Sweden in a new coalition, which was dissolved by the battle of Austerlitz. Pitt, whose state of health was previously declining, was sensibly affected by this event, as he was also by the Parliamentary attack upon his old associate, Lord Melville (see Dundas), not wholly parried either by minis-

terial influence or the merits of the case. As War Minister, he foresaw that the war on England's part must be naval, and he formed expensive coalitions with Continental powers that were to act on land. The failure of these coalitions must be traced largely to the selfishness of his allies, rather than to his own policies. In peacetime he sought Parliamentary reform, a stronger national credit, and an improved financial system. On his death, a public funeral was decreed by Parliament, as well as a grant of £40,000 to pay his debts.

K., 'England's Greatest Statesman' (1930); Petrie, C. A., 'William Pitt' (1935); Rose, J. H., 'Life of William Pitt' (2 vols., 1934); Barnes, D. G., 'George III and William Pitt, 1783–1806' (1939).

PITT, William (1708–1778), 1st Earl of Chatham, British statesman known as «The Great Commoner,» attempted to destroy French influence in America. See Chatham, Earl of.

PITT, Diamond. See Diamonds.

PITT, Fort. See Pittsburgh.

PITTACUS, one of the seven Grecian sages: b. about 650 B.C., d. 569. He assisted in the overthrow of the tyrant Melanchrus, led the Mytilene forces against the Athenians in a contest for Troad coast territory, slaying Phryno in single combat. He was raised to the dictatorship, and ruled successfully for 10 years. He wrote poems and originated the truism, «It is hard to be good.»

PITTI (pĭt'tē) **PALACE,** a celebrated Florentine palace, the second in size in the world. See Florence.

PITTMAN, Key, United States Senator: b. Vicksburg, Miss., 19 Sept. 1872; d. Reno, Nev., 10 Nov. 1940. Educated by private tutors and at Southwestern Presbyterian University, Clarksville, Tenn., he began the practice of law in Seattle, Wash., in 1892. In 1897 he went to Alaska in the Klondike gold rush; and at Nome he helped organize the «consent» government in 1899, became first district attorney there, and represented the local miners in their fight against a conspiracy to rob them of their mining claims in 1901. Returning to the United States, he settled in Tonopah, Nev., where he became president of the First National Bank. In 1912 he was elected United States Senator by popular vote, later confirmed by the Nevada legislature, to fill the unexpired term of George S. Nixon who had died in office; since that time he was re-elected to the Senate in every election up to and including that of 1940. Known as the «Silver Senator,» he put through the eight-power silver agreement for the stabilization of the world silver market at the London Monetary and Economic Conference of 1933. He was chairman of the Senate Committee on Foreign Relations after 1933, led the Senate fight for the first Neutrality Act, and sponsored the amendment to that act permitting trade with belligerents on a cash-and-carry basis.

PITTS, Hiram Avery, American inventor: b. about 1800; d. 19 Sept. 1860. He was the son of Abiah Pitts, for several years a village blacksmith in Winthrop, Me. After attending the district school, he learned the art of making wrought-iron implements from his father and, on the death of the latter, carried on the family trade for a short while until he decided to devote all his time to his inventions. His earliest work concerned the development of a chain-type hand pump and a treadmill operated by horsepower, for which he obtained patents. Thereafter he joined his brother John in a partnership and began producing treadmill machines for use throughout New England. These were first used to supply power for the so-called «Ground Hog» threshing machines. The threshers next attracted Pitts' attention, and in 1834 he constructed a combined threshing and portable fanning mill, the principles of which guided the development of similar machines for more than 50 years. In 1847 he moved his equipment to Alton, Ill., where he continued to experiment and improve upon his invention. By 1852, when he had again moved to Chicago, the improved «Chicago-Pitts» threshing machines were in extensive use in the major grain-raising areas of the United States. Additional inventions for the separation of hemp fibres and corn milling are also attributed to him.

PITTSBURG, Calif., manufacturing city of Contra Costa County, alt. 21 feet, on the Southern Pacific and Santa Fe railroads and the San Joaquin and Sacramento rivers; 45 miles southwest of Sacramento. There are many large factories here for steel and chemical products; rubber goods; lumber and building supplies; and canned fish. Coal was discovered here in 1863. Until 1911, when the town was chartered as a city, the name was Black Diamond. It has a mayor and council as well as a city manager. Pop. (1940) 9,520.

PITTSBURG, Kans., city in Crawford County; alt. 932 feet; 128m. S. of Kansas City; on the Atchison, Topeka and Santa Fe; St. Louis-San Francisco; Kansas City Southern; and Missouri Pacific railroads. It was first settled as a mining camp, and has always been an important coal center, situated at the heart of one of the largest bituminous fields in the United States. Lead and zinc are also mined in this region, and after the first zinc smelter was set up, in 1878, Pittsburg for some years held a leading place as a zinc-smelting center. There are also oil and gas fields near by. Railroad shops are located here. Pittsburg is the seat of a state teachers' college. Incorporated in 1880, it became a city of the first class in 1906. Pop. (1930) 18,145; (1940) 17,571.

PITTSBURGH, Pa. (sometimes incorrectly spelled Pittsburg), metropolis of the Ohio Valley and county seat of Allegheny County, located at the junction of the Allegheny and Monongahela rivers, which here unite to form the Ohio in lat. 40° 27′ N., long. 79° 57′ W. (Greenwich). Its location is picturesque and has been much admired. The business center, called the «Golden Triangle,» occupies the angle formed by the confluence of the two rivers. Its elevation is 740 feet above sea level. Extending for miles in every direction from this center, vast industrial plants and great residential sections have been built. The topography is markedly uneven, for the rivers have cut deep gorges by their flow.

The North Side of Pittsburgh, formerly the

city of Allegheny, occupies a relatively level tract along the Allegheny and Ohio rivers. This low-level area is flanked to the west of the Allegheny and to the north of the Ohio by lofty heights, up the sides and over the tops of which the city has crawled. On the south side of the Monongahela rises Mt. Washington, from which a fine panoramic view of the older portions of the city may be obtained. The wall of the canyon of the Monongahela recedes sufficiently to permit location upon level ground of that part of the city which once was the borough of Birmingham but which today is commonly known as the South Side. Behind this level ground rise a number of flat-topped hills, collectively called the South Hills district. This territory is the site of many of the newer residences. It is reached by vehicular tunnels and electric railways, which wind up many devious turns through the ravines to the level summits. The downtown section of Pittsburgh is connected with its populous East End districts by two wide boulevards (Bigelow Boulevard and Boulevard of the Allies) and a number of thoroughfares with street railway lines. Principal of these are Penn, Liberty, Fifth and Second avenues and Forbes Street. On the triangle itself, the main business streets, such as Wood, Smithfield and Grant, running north and south, and Fifth and Sixth avenues, running east and west, converge upon Liberty Avenue, which parallels the Allegheny river.

The climate of Pittsburgh is temperate, but sudden, sharp changes in temperature are not unusual. The average rainfall amounts to 36 inches a year. The average temperature is 75° in July, the hottest month, and 31° in January, the coldest. Because of its many industrial furnaces all burning soft coal, Pittsburgh used to be widely known as the «Smoky City.» Smoke abatement measures taken in recent years have made the nickname virtually obsolete, but the glowing furnaces, which led James Parton, the historian, to apply the striking appellation «Hell with the lid off,» still flare against the night sky. The city today is generally called the «Iron City» or «Steel City,» on account of the long predominance of those industries. Occasionally it is referred to as «The Workshop of the World.»

Area and Population.—The area of Pittsburgh is 51.37 square miles (54.5 including rivers). The population (returned by United States Census Bureau in 1940) was 671,659.

At the time of its first incorporation in 1794 the city was confined to the small triangle at the junction of the Allegheny and Monongahela rivers, bounded on the east by Grant's Hill. The area of this site was 320 acres, only half of a square mile. The greatest territorial addition occurred on 30 June 1868, when six adjacent townships, with a total area of 21.2 square miles were annexed. The largest single addition to the population, however, was made when, on 7 Dec. 1907, the city of Allegheny, having more than 150,000 inhabitants, was merged into the city of Pittsburgh.

The present official population does not adequately reflect the real size of the city, since many large nearby communities are unincorporated. Thus Pittsburgh, in 1930, ranked tenth in population among American cities, but seventh as a metropolitan district.

As in all of the larger industrial centres of North America, the population of Pittsburgh contains a large percentage of foreign-born and those of foreign parentage.

The 1930 census showed 68,592 from Germany (in both classes), 50,068 from Great Britain and Northern Ireland, 47,940 from Italy, 43,833 from Poland, 31,110 from Eire, and 21,704 from Russia. Since 1914 there has been a large influx of Negroes from the Southern States. The Negro population totaled 37,725 in 1920 and 54,983 in 1930.

Transportation Facilities.—The three rivers which traverse the city are important waterways and provide within the limits of the city proper a water-frontage of more than 40 miles. The Monongahela, by the construction of dams and locks, has been made navigable for a distance of more than 100 miles to the south and access is thus gained to the immense coal-fields of the northern part of West Virginia. The Allegheny is being canalized in the same way and thus the oil and coal-fields of the upper counties of western Pennsylvania are being reached. By the Ohio, the door is opened to thousands of miles of navigable water in the west and the south and access is had to the Gulf of Mexico and the oceans of the world. Water-borne commerce in the Pittsburgh district totalled 30,816,945 tons in 1937, exceeding the tonnage of any other American port except New York and Duluth-Superior.

The facilities for transportation by water have been enormously supplemented during the past century by the construction of steam railways. At present, Pittsburgh is served by the Pennsylvania, Baltimore & Ohio, Pittsburgh & Lake Erie (New York Central System), and Pittsburgh & West Virginia railroads, altogether nine main lines, besides branches, having no less than thirty main line tracks radiating from the city. In 1939 freight shipments originating in the Pittsburgh district totalled about 2,200,000 carloads for the principal railroads serving this area.

Travel within the city and its adjacent suburbs is facilitated by 30 bus routes and 565 miles (single-track) of electric railways. These street railways utilize streamlined cars of the most modern construction.

Pittsburgh is located on United States highways 8, 9, 22 (William Penn), 30 (Lincoln) and 40 (National), and state highways, 8, 26, 51, 80, 88, 519, 837 and 885. It is served by 10 inter-city bus lines. There are four airports in the district, including the huge Allegheny County Airport, with its 168-acre paved landing field, which is used by T.W.A. and Pennsylvania-Central Airlines.

One of the interesting means of communication between certain parts of the city that excites the curiosity of visitors are the inclined planes, which enable a quick ascent to be made from lower to higher levels. Some of these have been superseded by tunnels and boulevards, but one of the best known, the Mount Washington Incline, opposite the Pittsburgh & Lake Erie Railroad station, is still in operation.

Bridges.—Because of its peculiar topography, Pittsburgh is pre-eminently a city of bridges. More than 200 stand within the city limits and more than 600 in Allegheny County. Among the newest and most impressive is the George Westinghouse Bridge (1,560 feet) on the Lincoln Highway at East Pittsburgh. It was

opened in 1932 and its 460-foot central span is the longest single concrete arch in America. Also of the concrete arch type is the Homestead High Level Bridge, 4,200 feet long, completed in 1937. The Liberty Bridge (3,657 feet, completed in 1928) connects with the Liberty Tubes under Mt. Washington, which link the South Hills to the central business district. Both these bridges cross the Monongahela. The most notable bridges across the Allegheny are the Washington Crossing Bridge (2,630 feet, completed in 1924), and the Highland Park Bridge (2,640 feet, completed in 1939). The West End and North Side are joined by a bridge over the Ohio (1,889 feet, completed in 1932), while further downstream is the still longer Ohio River Bridge (7,300 feet, completed in 1931).

Manufactures and Mining.—The Pittsburgh industrial area ranks fifth in the United States in value of manufactures and in wages paid, being surpassed only by New York, Chicago, Detroit and Philadelphia-Camden. According to the latest biennial census of manufactures, taken in 1937, there were in this area 2,041 factories, with 29,751 salaried employees and 227,675 wage earners, turning out products valued at $1,746,908,000. Average wages amounted to $29.38 a week or $1,532 a year.

Pittsburgh lies at the heart of the largest and most productive coal-field on the continent, and has at hand one of the greatest fields of natural gas in the world. This abundance of cheap fuel at its command has naturally attracted to the city all those industries which depend upon fire for their successful prosecution. Pre-eminent among these is the iron and steel industry. Fifty of the 236 blast furnaces in the United States are located in the Pittsburgh district, and its rated steel capacity is one-fifth that of the entire country. In 1939, 6,456,000 tons of pig iron and approximately 8,644,000 tons of steel ingots were produced here, compared with 35,515,000 and 46,150,000 tons respectively in the United States as a whole.

Two of the largest steel concerns, Carnegie-Illinois and Jones & Laughlin, are located here Both have modernized their equipment recently, and the new Irvin Works of Carnegie-Illinois, situated on a hill near Clairton, includes the world's finest strip mill, with annual capacity of 672,000 tons.

Every variety of iron and steel product is manufactured in or around Pittsburgh, and the district leads in the fabrication of such diverse products as tubes, rolls, bolts and nuts, wire, wrought iron pipe and rolling mill machinery. A large proportion of the skyscrapers and bridges for which America is famous received their structural steel from the various mills of Pittsburgh, direct, or by way of the large fabricating plants there. Besides the Carnegie-Illinois plants, the United States Steel Corporation has other units, such as the American Steel and Wire Company and the National Tube Company, operating plants here. A pioneer in the making of pipe is the Spang-Chalfant Company.

The city also has factories equipped to make the most intricate machine tools. The Mesta Machine Company, for example, which largely furnished the new Irvin Steel Works, constructs among other things gas and steam engines, rolling mill machinery and steam-hydraulic presses.

The Pittsburgh Plate Glass Company, world's largest, maintains plants at Creighton and Ford City, Pa., and more than a quarter of the polished plate glass made in this country comes from western Pennsylvania. Production in 1939 totaled 36,190,000 square feet compared with 141,817,000 for the United States as a whole. Specialized glass and optical products are also extensively manufactured.

Electrical equipment in great variety, steam engines and turbines, air brakes, railway signals and other safety devices are shipped to all parts of the world by the companies named after George Westinghouse, inventor of the air brake, and their subsidiaries. Large Westinghouse plants are located east of the city at Swissvale, East Pittsburgh, Trafford and Wilmerding, and this section has come to be known locally as the Westinghouse Valley. George Westinghouse pioneered in drilling the first gas well in the city and in having a commercial supply piped in from Westmoreland County.

The Aluminum Company of America, which has a virtual monopoly in its field, originated in Pittsburgh and still maintains its research laboratories and one big plant nearby. It is one of the numerous enterprises established by the Mellons, who were primarily bankers. The Vanadium Corporation of America, whose plant is at Bridgeville, Allegheny Co., is equally well-known in its field.

The Armstrong Cork Company manufactures linoleum and floor tiles as well as stoppers for bottles. The H. J. Heinz Company sends its «57 varieties» of preserved foods all over the world. The Standard Sanitary Manufacturing Company (now united with the American Radiator Company) is famous for its plumbing fixtures and enameled ware. Pittsburgh was the original centre of the petroleum industry, which has since spread elsewhere. It is still the headquarters of the Gulf Corporation, among other large operators in oil and gas, and there are several refineries, two of which are of sizable capacity.

In recent years a great development has taken place in the chemical industries, especially those connected with the by-products of the coke industry. The Koppers Company, whose offices are in Pittsburgh, is the largest producer of domestic coke and one of the largest producers of coal tar. It has built more than 75 per cent of America's by-product coke ovens. During wartime Pittsburgh produces an unusual quantity of high explosives.

Western Pennsylvania, West Virginia and Ohio together constitute the most productive bituminous coal-field in the world. In 1939 western Pennsylvania alone mined some 58,720,000 net tons of this fuel, 15 per cent of the United States total of 389,298,000 tons. Coal-mining is an exceptionally competitive industry, but the Pittsburgh Coal Company produces a little more than one-tenth of the western Pennsylvania total.

The principal experiment station of the United States Bureau of Mines is located in Pittsburgh. It co-operates with branch experiment stations in other places in testing fuels, processing minerals, investigating and preventing accidents and instructing mine officials and miners in first-aid, accident prevention and rescue procedures. At Bruceton, Pa., 13 miles from Pittsburgh, the bureau has an experimental mine where explosions are artificially produced to determine the relative safety of explosives.

Banking Facilities.—Pittsburgh had (1939) 38 banks, capitalized at $46,845,500, with deposits of $1,127,834,000 and $165,380,574 surplus and undivided profits. Total resources of these banks on 30 June 1939 amounted to $1,381,626,000. The oldest bank in the city is the Farmers Deposit National Bank, which celebrated its centennial in 1932. Largest is the Mellon National Bank with resources of $408,234,000. One of its past presidents was Andrew William Mellon, former Secretary of the Treasury. The city ranks sixth in bank clearings, which totalled $6,118,971,448 in 1939.

City Government.—Pittsburgh's municipal government, mayor-councilmanic in form, operates under provision of the Pensylvania Acts of Assembly governing cities of the second class, and the duties and functions of the various city officers are delineated and supervised by state legislators.

The city's finances are derived from taxation under a graded tax law imposed by the State Assembly in 1913, restricting the tax rate levied on buildings to one-half that levied on land. This law does not apply to school taxes or taxes for Allegheny County, whose seat of government is Pittsburgh.

Under existing conditions the municipality exercises many functions only with approval of the State, which even directs the procedure in the hiring and discharging of city employees and sets up pension systems for all city employees and salary schedules for some of them. A determined effort is being made to remove this undesired paternalism.

The chief officers of the city government are elected to four-year terms: the mayor, or chief executive; nine councilmen, the legislative branch, and a controller, the final funds disbursement authority.

Governmental activities are conducted by special departments, each supervised by a director, who is a member of the mayor's cabinet and directly responsible to the executive for the conduct of his department. The principal departments and their functions follow.

The Public Works Department has 11 bureaus charged with maintenance and operation of the city's physical properties, the water system, streets, highway and sewer maintenance, bridges, light, engineering and design, parks and recreation, testing laboratories, municipal garage, garbage collection and incineration, and the general office force of senior and junior engineers, statisticians, accountants, supervisors, inspectors, stenographers and lesser personnel.

The Public Safety Department operates the police and fire bureaus and division of detectives in general exercise of police authority. The Law Department, with its staff of attorneys and investigators, prosecutes all legal business for the city, superintends and advises on councilmanic ordinances, contests suits against and enters suits on behalf of the city.

The Department of Health administers the city's municipal hospitals, maintains staffs of sanitation investigators, and co-operates with the Department of Welfare, which supervises the City Home and Hospitals, at Mayview, Pa., maintains a staff of trained sociological workers and nurses, and generally guards and promotes public health. The Department of Lands and Buildings supervises about 1,600 parcels of real estate, 540 municipal buildings and about 80 residential properties acquired through tax sales.

The City Treasury, through the appointed city treasurer, collects all tax monies and other money due the city and disburses money upon authorization of the city controller. The Board of Tax Revision and Assessment and the Bureau of Water Assessors, which are separate entities, respectively fix the tax and water payments due from the taxpayers and users of water. The Department of Supplies supervises the purchase of all materials needed in operation or maintenance of city government.

The Civil Service Commission sets standards for employment, devises tests and examinations, supervises them and grades all applicants for employment with the municipality. It is a judiciary body when employees are derelict or inefficient in duty, with both power of dismissal and restoration to duty of employees within its jurisdiction. The total receipts and expenditures of the municipality in 1939, according to the Controller's Annual Report, were: Receipts, $24,913,240; Expenditures, $24,296,550. Pittsburgh's real estate valuations for tax purposes in 1940 were: Land, $513,117,520; buildings, $533,906,340. Tax rates were 23 mills on land, 11.5 on buildings, 11.75 on schools. The 1940 tax levy total was $30,244,156.

Notable Buildings.—Pittsburgh has an unusual variety of architecture, especially in church, hospital, bank and office buildings. Most of the more notable buildings are located either in the «Golden Triangle» (designated by T) or in the Oakland «Civic Center» (designated by O). Some of these are described elsewhere in this article. Two of the oldest landmarks are the Forsythe Log Cabin (East Liberty), built during the American Revolution, and the original Block House of Fort Pitt (T). The Block House, built of brick in 1764, is the only remaining relic of the city's early colonial period. The Allegheny County Court House (T), a Romanesque structure designed by the well-known architect H. H. Richardson, is in sharp contrast to the modern City-County Building (T) and the new Federal Building (T). The latter, completed in 1934, houses the main post office and other governmental offices. Though only 10 stories high it contains 40 acres of floor space.

The Cathedral of Learning (O) of the University of Pittsburgh, which towers over the «Civic Center,» is the tallest school building in the world. It is of Gothic design, faced with white limestone. Near by are the Heinz Memorial Chapel (O) and the Foster Memorial (O), a concert hall and museum built in memory of Stephen Collins Foster, both part of the University of Pittsburgh. The Mellon Institute (O), a famous experimental industrial laboratory given to Pittsburgh by A. W. and R. B. Mellon, is housed in a monumental edifice in the Greek Ionic style entirely surrounded by huge monolithic columns. On the North Side in Riverview Park stands the Allegheny Observatory, established in 1859. Its working telescope is a 30-inch photographic refractor, but it also has a 13-inch refractor used exclusively for visitors and a 30-inch reflecting telescope. The Buhl Planetarium, also on the North Side, is the fifth planetarium to be built in this country; it was opened in 1939.

Soldiers' and Sailors' Memorial Hall (O) is

modelled on the Mausoleum of Halicarnassus and contains many historical relics. Syria Mosque (O) is the city's largest auditorium, seating 3,850 persons. The Medical Center (O) includes the Municipal, Western Pennsylvania Psychiatric, Children's, Eye and Ear, Presbyterian and Woman's hospitals, the Falk Clinic and the University of Pittsburgh medical school. The Historical Society of Western Pennsylvania (O) is a centre of research.

Among the city's best-known social clubs are the Duquesne (T) and the Pittsburgh Club (T) for men, and the Twentieth Century (O) for women. The William Penn (T; 1,600 rooms) is the largest hotel. The most ornate office building is the Union Trust (T) a 15-story Gothic structure. Following are the six tallest «skyscrapers»:

Name	Height, feet	No. of stories
Gulf (T)	575	42
Cathedral of Learning (O)	535	42
Grant (T)	485	40
Koppers (T)	475	34
First National Bank (T)	387	26
Oliver (T)	347	25

Churches.—Almost every religious denomination is represented among the 550 churches in the city. Pittsburgh is the seat of a Roman Catholic and a Protestant Episcopal bishop, and is the seat of the Board of Missions to the Freedmen of the Southern States of the Presbyterian Church, and of all the ecclesiastical organizations of the United Presbyterian Church in America. Among the church buildings outstanding for dignity and beauty a few may be listed: the Calvary (Protestant Episcopal) on Shady Avenue, is a fine example of Early English Gothic. The East Liberty Presbyterian Church (a gift of Mr. and Mrs. Richard B. Mellon) is an impressive Gothic building of which Ralph Adams Cram was the architect. An institutional church, it occupies an entire block at South Highland and Penn avenues, and cost approximately $4,000,000. St. Paul's Cathedral in the Civic Center, and the Sacred Heart Church on Shady Avenue, are among the most notable Roman Catholic churches. The latter, not yet completed, is Late Perpendicular Gothic, designed by Carlton Strong, and remarkable for its elaborate symbolism. The First Baptist Church, in the Civic Center, is an interesting example of French Gothic and the German Evangelical Protestant Church, in the older section of the city, is especially known for its beautiful steeple. The Synagogue of the B'Nai Israel congregation on North Negley Avenue is circular in form and of Byzantine style. The temple of the Rodef Shalom congregation on Fifth Avenue is an imposing structure. The Heinz Memorial Chapel of the University of Pittsburgh suggests the Sainte Chapelle of Paris, both in its exterior and in the beauty and in extent of its windows. Charles Z. Klauder was the architect and Charles J. Connick designed and made the glass which, with the excellent examples elsewhere, make Pittsburgh a centre of this art.

Parks.—There are 1,971 acres of park land distributed among the main population centres within the city limits, divided into four major parks, Frick, Schenley, Highland and Riverview, and 15 neighborhood parks. These parks conserve some of Pittsburgh's finest characteristic rugged topography with their deep, wooded ravines secluded from city conditions, and their high hills commanding dramatic views of the river valleys. In addition to the usual park drives, trails, open meadows and ornamental planting for passive recreation, there are provisions for all kinds of active recreation, including golf, tennis, bowling on the green, horseback riding, picnics, baseball, mushball, field meets, cross-country running, swimming and ice-skating. Most centrally located and intensively developed is Schenley Park (422 acres), which includes the famous Phipps Conservatory, open throughout the year, and holding nationally known free flower shows twice annually. This park contains handsome perennial gardens, water lily pools, an azalea garden, open-air theatre, and many memorials, most noted of which are: Mary E. Schenley Fountain, George Westinghouse Memorial, Robert Burns statue and the statue of E. M. Bigelow, who was instrumental in obtaining Schenley Park from the Schenley family.

At the entrance to Highland Park (367 acres) is a magnificent rose garden leading to large reservoirs, surrounding which is a popular promenade commanding views of the Allegheny River Valley. Near by is the statue of Stephen C. Foster, the famous Pittsburgh song writer and composer, and the completely modernized free Highland Park Zoo with its comprehensive zoological collection. Frick Park (459 acres) preserves the largest area of hills and ravines in their natural condition, free of vehicular highways, accessible only to pedestrians by nature trails where the native bird, animal and plant life is conserved. On the highest point in Riverview Park (240 acres) is located the well-known Allegheny Observatory operated by the University of Pittsburgh. This is the most popular park for picnics. Nature museums and nature education programs are conducted by park naturalists in Frick, Schenley and Riverview Parks. In Highland and Schenley Parks lakes are stocked for children's fishing.

Supplementing the city parks, the County of Allegheny maintains South Park (2,500 acres), and North Park (2,000 acres) both including golf courses, tennis courts, large swimming pools and picnic facilities. South Park is best known for its annual free County Fair, and North Park for its large lake with boating facilities and its archery range.

Schools.—The public schools of Pittsburgh enrolled 104,372 pupils in 1939. In addition, the Board of Public Education conducts free adult education classes for 39,309 persons in 82 evening schools conveniently located throughout the city. Altogether there are 4,050 teachers and supervisors assigned to 150 public schools, including 115 elementary, 21 high, 7 vocational and 7 special schools. Most of the elementary schools are of the platoon type. The three largest high schools, Allderdice, Westinghouse and Peabody, all have elaborate equipment and enrolments of more than 3,000 pupils.

The Board of Public Education consists of 15 members appointed by the judges of the Court of Common Pleas for a term of six years and serving without pay. The entire management of the school system is vested in this board, which elects the educational head of the system, called the Superintendent of Schools, also for a term of six years.

Many Catholic children receive their educa-

tion in parochial schools. There are 108 of these in Pittsburgh, including 28 high schools, with 1,092 teachers and an enrolment of 38,543 (1938). There are also several private preparatory schools for both boys and girls. Largest of these are the Ellis and Winchester-Thurston schools for girls and Shady Side Academy for boys. The latter maintains both a junior school in the city and a senior school on a 125-acre country estate.

Colleges and Universities.—The oldest and largest institution of learning is the University of Pittsburgh. (q.v.)

Duquesne University was opened as a college of arts and letters in 1878 and incorporated in 1881 as the Pittsburgh Catholic College of the Holy Ghost. A university charter was obtained in 1911 and the present name adopted. Duquesne University now comprises a college of liberal arts and sciences, graduate school, and schools in education, law, music, business administration, pharmacy, drama and nursing. The university is conducted by the Fathers of the Congregation of the Holy Ghost, but students of all denominations are equally admitted. It is a co-educational institution and the enrolment in 1940 was 3,158. There are two divisions of the university, the downtown division and the uptown or campus division. The downtown division is located in the Fitzsimmons Building, a business structure situated in the heart of Pittsburgh's financial district, where day and evening classes in commercial education, business administration and related subjects are conducted. The law school and the law library are also located in this building. The uptown or campus division is situated on an eminence overlooking Pittsburgh's Golden Triangle and commands a view of the Monongahela and Ohio rivers. The latest addition to the group of university buildings is the library, which was opened in the fall of 1939.

Pennsylvania College for Women, a non-denominational college of liberal arts and sciences, was founded in 1869. Its beautiful Woodland Road campus provides a natural amphitheatre for May Day fetes and ample grounds for athletic fields. Among the newer college buildings are the Louise C. Buhl Hall of Science and the James Laughlin Memorial Library. Mount Mercy College, conducted by the Sisters of Mercy, was founded in 1929 as a college of liberal arts and sciences. Its airy campus on a hill overlooking Fifth Avenue affords a panoramic view of the city. St. Joseph's Hall was erected in 1932 to house the extracurricular activities of the students, and Aquinas Hall was added to the group of buildings in 1936 to be used for lectures and recitations.

Carnegie Institute of Technology was founded by Andrew Carnegie primarily to aid in the education of the young people of Pittsburgh. Since its opening in 1905 it has gradually expanded both physically and educationally until it has become recognized as one of the leading technological institutions of the country. Its campus, adjoining Schenley Park, embraces 60 acres. The institute comprises four colleges and two laboratories for scientific research—the Coal Research Institute and the Metals Research Laboratory. Margaret Morrison Carnegie College, the women's college, offers undergraduate major work in eight fields. Carnegie Library School, organized in 1901, became an integral part of the Carnegie Institute of Technology in 1930 since which time its graduates have received a degree upon completion of the work. In the beginning its training was confined to library work with children, but since 1918 courses have been added in general and high school library work. The College of Fine Arts includes the departments of Drama, Music, Architecture, Sculpture, and Painting and Design. The fourth college, that of Engineering, gives instruction in the standard branches of engineering, and is the only college which grants a degree on the completion of its course in printing. The evening classes of the institute are very numerous and enroll more students than attend by day. When Carnegie Institute of Technology organized its Department of Drama in 1914, it rendered a pioneering service in this country. Since Shakespeare's birthday in 1914, when the Carnegie Theatre was opened with Shakespeare's 'The Two Gentlemen of Verona,' over 500 plays, drawn from all ages and all countries, have been produced. The theatre auditorium is renowned for its beauty, and the stage is large and flexible and completely equipped with modern lighting apparatus.

Two days after the occupation of Fort Duquesne by the British and Colonial troops, on 24 Nov. 1758 a sermon was preached, the first by a Protestant minister to be delivered west of the Allegheny mountains. The preacher, the Rev. Charles Beatty, was a Presbyterian, and from that day to this the Presbyterians have been an important element in Pittsburgh. The Western Theological Seminary was established in 1825 by the Presbyterian Church. The present seminary buildings, a group in English Collegiate Gothic, are located on Ridge Avenue, adjacent to West Park. Pittsburgh became the location of the only United Presbyterian theological seminary in America with the merger in 1930 of two schools into the Pittsburgh-Xenia Theological Seminary. The Pittsburgh Theological Seminary was founded in 1825 in Allegheny, and the Xenia dates from 1794. The Reformed Presbyterian Theological Seminary, located in the east end of the city, was founded in 1856.

In the year ended in June 1939 there was a total enrolment of 24,975 students in the institutions of higher learning in Pittsburgh.

Musical Activities.—The Pittsburgh Symphony Orchestra, founded in 1895 and disbanded 15 years later, was reorganized in 1927 and gives concerts at Syria Mosque twice weekly during the winter season. The orchestra has 89 permanent members, and is conducted by Fritz Reiner. Pittsburgh's New Friends of Music, the Art Society and the Y.M. & W.H.A. Musical Society present outstanding soloists and string quartets on a subscription basis. Among the numerous choral groups in the city are the Bach Choir and the Mendelssohn Choir, both of which consist of mixed voices. Free organ recitals are given weekly at Carnegie Music Hall, Carnegie Hall on the North Side, and Heinz Chapel on the University of Pittsburgh campus.

Carnegie Institute.—On 25 Nov. 1895, the Carnegie Library was inaugurated, and, in declaring it open and free to the public, Andrew Carnegie announced that he desired to establish within the Library building the Carnegie Institute, for the development of which he gave, at

that time, an initial endowment of $1,000,000. An art department and a popular science museum were immediately created. The institute grew rapidly, and the building was reconstructed in 1907. This building is designed in the Renaissance style of architecture. The entrances are flanked by bronze statues of Shakespeare, Bach, Galileo, and Michelangelo. The interior, which is resplendent with the finest foreign and domestic marbles, provides a stately foyer. The department of fine arts controls the galleries of architecture, sculpture, paintings, and engravings. The collections have grown until they already comprise a representative assemblage of the best works of American and European artists. Here is annually held an international exhibition of paintings to which the artists of the world contribute, the only «Salon» in America. The museum lays special stress upon the natural sciences and the industrial arts. The staff consists of about 40 persons, a number of whom are engaged in special scientific researches in connection with their other duties. The collections in the museum extend generally into all the avenues of scientific exploration. Its paleontological collections, gathered in part by its own staff from its own fields in the Western States and in part by purchase from European sources, is one of the largest and most comprehensive in the world. Among the museum's big game collections are trophies that were shot in Africa by Childs Frick and by the late President Theodore Roosevelt. The collection of the birds of Pennsylvania is thought to include every bird that passes through that State, and a book showing the pictures of these birds in color, prepared by W. E. Clyde Todd, curator, was published in 1940. The bird collection in general; the fishes of the rivers and seas of the world; the large group of ivories contributed by H. J. Heinz; the many objects of art given by Herbert DuPuy; the minerals, showing everything that is dug from the earth; the Indian reproductions of tribal customs; the rich laces and fans from many countries; the pottery, china, and glassware, showing these arts at their best; these, and hundreds of other objects, serve to instruct and delight the visitors who throng the institute halls.

Carnegie Library.—The Carnegie Library of Pittsburgh is not endowed but is maintained by city tax funds. With 1,041,568 volumes (1940), it is the largest municipal library in Pennsylvania and eighth largest in the United States. The library has 14 branches and a fluctuating number of stations, most of which are in schools and summer camps. In 1939, 4,243,273 books were borrowed from all its divisions—eight books per capita of population. The library has always specialized in scientific and industrial literature, and its technology department, with 106,000 books and 910 currently received periodicals, is considered to be one of the finest in the country. As the first technical division established in any library, it is unsurpassed in its files of early scientific journals. The reference department of the central library includes subdivisions for fine arts (with a special collection of architectural books), music, and local history. Excluding technology, it has 151,000 catalogued volumes and subscribes to 62 daily newspapers and 986 other periodicals, currently displayed in the periodical room. The boys and girls' department of the library does extensive work with children, which includes the giving of some 2,600 book talks and story hours annually. The schools department operates under an unusual plan of co-operation with the Board of Public Education, whereby elementary and high school libraries are supervised by the department. A feature of the adult lending department is the endowed Gillespie room, which is stocked with a selection of the best books of all times and designed for leisurely reading. Among special services of the library may be mentioned the office of the reader's consultant, maintained for the purpose of advancing adult education, and the division for the blind, which distributes books in Braille and «talking books» in western Pennsylvania and West Virginia.

Other Libraries.—In addition to the Carnegie Library, described above, there are a number of other libraries of importance in the city. The Carnegie Free Library of Allegheny, founded by Mr. Carnegie in 1890 when Allegheny was an independent municipality, is also maintained by the city for the benefit of the residents of the North Side. The University of Pittsburgh includes the General Library in the Cathedral of Learning and various collegiate libraries such as those in the School of Law and the School of Medicine, and the collections in the departments of chemistry, physics, fine arts and others, varying in size from 100 volumes to 40,000 volumes. A special room of the General Library houses the Darlington Memorial Library, a gift of a distinguished local family. This collection is especially strong in American history and in 18th and 19th century literature. The university's collection of books and music in the Stephen Foster Memorial is the most complete assemblage anywhere of material relating to the life and works of Stephen Collins Foster. Other notable research libraries are those of the Mellon Institute, the Historical Society of Western Pennsylvania, the Allegheny Observatory, the Western Theological Seminary, and the Allegheny County Law Library.

Foundations.—The Buhl Foundation, established in 1928, has made many grants to promote social work and regional economic effort in Pittsburgh. One of its major projects has centred in the building of Chatham Village as a demonstration of the practicability of large-scale housing enterprises. In 1939 it presented to the city the Buhl Planetarium. The Maurice and Laura Falk Foundation began its work of promotion of economic progress in 1930. An interesting local project was begun in 1937 when the foundation granted $300,000 to Carnegie Institute of Technology for the endowment of a professorship of social relations to develop a program of education in the relation of science and technology to society. The Henry C. Frick Educational Commission grants scholarships for summer study to public school teachers of Pittsburgh. Other foundations exist to promote similar philanthropies and among these is a proposed (1940) Mellon Educational and Charitable Trust.

Social Welfare.—Approximately 400 agencies are included in the 1937 edition of the «Directory of Social Agencies of Pittsburgh and Allegheny County,» of which about one-tenth are public. Since 1928 the Community Fund has been financing many of these agencies, and $2,650,000 was raised as a maintenance fund for the year 1939-40. The important function

of social planning for all the organizations engaged in social work in this community is carried on by the Federation of Social Agencies. The Department of Public Welfare of the city functions as the Institution District for the City of Pittsburgh. In this capacity the department is responsible for maintaining the City Home and Hospitals situated at Mayview, Pa. This hospital cares for residents of the city who are unable to pay for care at any other hospital. The Pittsburgh City Home and Hospitals is divided into a general hospital for care of the acutely ill; an infirmary for care of the chronic sick; and a mental hospital for care of psychotic patients. In 1940 there were 4,277 patients; over 3,000 were mental patients.

Housing.—Most of Pittsburgh's 700,000 residents live mainly in dwellings atop the hills which breast the Allegheny, Monongahela and Ohio rivers. The low-lying areas along and between the rivers have long since become inutile as residential neighborhoods. These areas —Lower North and South Sides, the Strip and Manchester—have seen a concentration of commercial and industrial building rather than residential development since the turn of the century. As Pittsburgh has grown into one of the leading industrial cities of the nation, it has concurrently developed many obsolescent properties. To remedy this situation, the Pittsburgh Housing Authority has engaged in a program of slum elimination and the building of 3,073 new low-rent homes for the city's lowest income families. Three giant public housing projects, Bedford Dwellings and the two Terrace Villages, are located midway between the «Golden Triangle» and Oakland in what was formerly known as the Upper Hill district. Even before the reformation of three rough, unused hilltops (Ruch, Goat, and Gazzam hills) into the new Housing Authority communities, Pittsburgh's city planners had developed modern blue prints for the proper zoning of residential neighborhoods. Much of the planning has been directed toward a complete elimination of new home building near the rivers, where there is the possibility of floods, and there has been a noted trend toward suburban living. Famous throughout the country is the Buhl Foundation's Chatham Village housing project, located in Mt. Washington, where more than 290 white-collar families live in a «garden community» development at moderate rentals. These homes were established as models for private enterprise to follow in the large-scale residential field.

Water Supply and Sanitation.— Pittsburgh's domestic, industrial and municipal water consumption is approximately 90,000,000 gallons daily, produced entirely by the city's water system at a gross production cost of $1,170,000, or roughly $54 a million gallons. The municipality achieves purification by the slow sand filtration process. Pittsburgh was among the first cities in America to adopt this method on a large scale. The municipal supply passes through 46 acres of filtration beds in the Allegheny River at Aspinwall, Pa. The beds were erected in 1907–10, are under roof and cost approximately $7,000,000. The process has been efficient without abnormal upkeep cost and use of chemicals, except for periodical treatments of soda ash to correct acidity. Hourly readings for acid content are taken and necessary corrections made at the filtration beds. Inasmuch as the source of supply is not constant in volume and industrial contamination can never be removed, the present water system has been declared inadequate for the proper industrial development of the city and a barrier to the settlement in Pittsburgh of such industries as textile, rayon and paper mills.

Prior to a municipal construction program (1938–40), many districts of Pittsburgh had suffered from low water pressure, with consequent hazards to health and sanitation. Under this program, more than $1,170,000 was spent in rejuvenating the water system; $4,000,000 on a new sewerage system, and $1,000,000 for a municipal garbage incinerator, a third factor in the city's sanitation. Before the construction program, a costly item in water service maintenance was the high pressure delivery lines and distribution systems, which constantly developed leaks under stress of service in the mountainous sections of the city. This was remedied by erection of huge steel tank reservoirs in those sections, by reservoir main reinforcements and service line extensions. Three major reservoirs receive their supply from the 50,000,000 gallon filtration bed reservoir, whence the water is pumped across the river to the city's principal pumping station, which delivers to the two Highland Park reservoirs. The filtration plant at Aspinwall pumping station pumps water to the Lanpher Reservoir. A system of five additional pumping stations draws the water from the three reservoirs to the minor reservoirs and tanks for delivery into the 1,000 miles of mains and service lines, and approximately 7,000 fire hydrants.

Pittsburgh's new sewer system is 12.7 miles long. This system removed an annual health hazard caused by storm-flooded cellars, due to the inadequacy of the old system. All sewage enters the rivers.

Pittsburgh's new municipal incinerator, which went into operation 1 March 1940, is designed to save $300,000 to $400,000 annually in the disposal of garbage and rubbish, a service which formerly cost $1,500,000 yearly under private contract. A free ash collection service, made possible by the savings, eventually will be inaugurated to end the custom in certain sections of dumping ashes into the streets to clog sewers and impair sanitation.

Health.—Pittsburgh's health record, as reflected in its mortality rates from principal causes, compares favorably with other large cities in this country and Europe. The crude death rate in 1939 was 12.0. The official agency responsible for the public health is the Department of Public Health which co-operates closely with the many unofficial health agencies and private hospitals in the city. The present health department is a continuation of the original Board of Health established in 1868 and organized in its present scope in 1909. Hospital facilities under the direction of this department include a new 225-bed Municipal Hospital for Contagious Diseases and a modern 460-bed sanatorium for the treatment of tuberculosis. With such hospital facilities, Pittsburgh is amply prepared to safeguard its citizens from epidemic diseases. The department's routine activities are concerned with diagnosis and control of communicable diseases; school medical inspection; inspection and regulation of housing, plumbing and sanitation; food and milk control; and smoke prevention.

An outstanding achievement in health work in Pittsburgh was the historic conquest of typhoid fever with a reduction in the death rate from 144.6 per 100,000 in 1900 to 0.4 in 1939. That typhoid fever has been practically eliminated is principally due to the efficient filtration plant which Pittsburgh maintains. Among municipalities, Pittsburgh recently took a leading part by conducting an intensive pneumonia control campaign (1936–39) and by being the first city to inaugurate the free distribution of specific antipneumococcic serum. That the city benefited is evident from the trend in the pneumonia death rate, mortality falling below 75 per 100,000 population for the first time in half a century.

Dr. Ralph Mellon and associates at West Penn Hospital have pioneered in the analysis of sulfanilamide, the «wonder drug,» and were pioneers in applications of the drug to pneumonia. In 1938 they published an important book on 'Sulfanilamide Therapy of Bacterial Infections' (C. C. Thomas, Springfield, Ill.).

Radio.—The world's first commercial radio broadcasting station, KDKA, was opened at East Pittsburgh on 2 Nov. 1920, with the transmission of the Harding-Cox election returns. This station, owned and operated by the Westinghouse Electric Company, now broadcasts, with a power of 50 kilowatts, from Allison Park, with main studios in the Grant Building, Pittsburgh. The 40-kilowatt Westinghouse shortwave station, WPIT, is heard clearly all over the world. Its transmitter is at Saxonburg, Pa. There are four other radio broadcasting stations in the city. One of the real pioneers in the development of radio was Prof. R. A. Fessenden (1866–1932), who began his experiments with wireless in 1898 while teaching electrical engineering at the Western University of Pennsylvania (now the University of Pittsburgh). On 24 Dec. 1906 he broadcast «a song, the reading of a verse, a violin solo and a speech» from an improvised sending set at Brant Rock, Mass. This broadcast, heard by numerous astonished ship operators in the North Atlantic, was the first radio-telephone program ever transmitted any considerable distance.

History.—*Early Period.*—The famous and historic Point, at the confluence of the two rivers that unite to form the Ohio, has been the scene of many struggles and much conflict over its possession. Wandering tribes of Indians were the first to see this important place; next came the exploring French and then the English, both of whom claimed it. In 1749 Celeron was sent to take possession of the region as French territory. He used the unique method of burying leaden plates in the ground as markers and to warn all who could read French that the territory belonged to France. However, Christopher Gist, agent for the Ohio Company, came here in 1750, treated with the Indians, and planned to found a colony nearby. In 1753 George Washington, a youth of 21, appeared on the scene, standing at the Point and writing in his diary, «I have spent some time in viewing the rivers and the land in the fork; which I think extremely well situated for a fort.» He had been sent on a mission from Virginia to the French at Fort Le Boeuf on French Creek, and on his journey was to make a study of the lands suitable and desirable for building fortifications for the English claims and to warn the French against encroaching on English territory. Virginia based her claim to all the Ohio River territory on her charter from England. France based her claim on the explorations of La Salle. In 1754 Governor Dinwiddie of Virginia was so impressed by George Washington's description of the Point that he sent a small body of troops under Ensign Ward to build a fort. Before they had a chance to do more than erect a stockade, or even give a name to it, a detachment of French with Indians arrived and forced them to leave. The French immediately built a fort and called it Fort Duquesne, honoring the Colonial Governor of Canada. They defended this fort against two attacks by the English. The first attack was under General Edward Braddock. George Washington was a member of the Colonial troops and tradition states that he advised the British general upon Indian war tactics and methods of fighting and urged him to pursue the same methods, such as firing from behind trees. The general refused and went down to inglorious defeat, mortally wounded, his soldiers in retreat. The battle took place 9 July 1755 on the site of the Edgar Thomson Steel Works in Braddock. The second encounter, which also resulted in defeat for the British, was directed by Major James Grant, leading an advance force of Forbes' expedition in 1758. For England, again wishing to press her claim to the coveted land at the forks of the rivers, had dispatched General John Forbes with a well equipped army, including the young provincial officer, George Washington. The French knew by this time that further resistance was useless, due to lack of reinforcements and supplies from Canada. They blew up their powder magazine, destroyed Fort Duquesne and withdrew from the site. The way was now cleared for English possession, and on 25 Nov. 1758, General Forbes marched to the abandoned spot, had the English flag raised, and immediately named the place Pittsburgh in honor of William Pitt. This was the first use of the name that has persisted to this day, even to the original spelling. Forbes immediately began the erection of a log fort, which was called Fort Pitt, and was an important military post for years thereafter. From this beginning there emerged a village about the fort. Forbes' successor, General John Stanwix, began the erection of a formidable Fort Pitt near the Point in 1759, faced with brick and surrounded by a ditch. The works were said to have cost £60,000 sterling.

Later period 1760–1860.—The village that grew up around this fort was composed of a military garrison, traders and their families, and Indians. Some of the Indians were friendly and became a part of the settlement; others were hostile and remained a menace to the white settlers until 1790 when it was safe to live here without protection of an armed garrison. The ever-present danger of attack from the Indians and the suffering and hardship of the journey over the trackless forests and high mountains did not deter the early settler, and by 1760 the settlement was well established. The high mountains made a natural division so that inhabitants when once here were forced to develop a self sufficient and independent way of living. Pontiac's Conspiracy brought an attack on the fort, into which the inhabitants had been gathered, in July 1763. Thereby was brought about one of the most important events in the

history of Pittsburgh and the West, the march of Colonel Bouquet across Pennsylvania, his encounter with and defeat of the Indians at Bushy Run about 25 miles east of Pittsburgh, and relief of the fort. The following year he built the redoubt which is all that remains of Fort Pitt today.

Between 1770 and 1780 Pittsburgh emerged from a wilderness settlement into a new world. The Penn's Manor of Pittsburgh, which had been surveyed in 1769, was opened for sale in 1783. New settlers arriving, built new homes, churches and inns; a newspaper, *The Pittsburgh Gazette,* was started in 1786 and a year later the Pittsburgh Academy, forerunner of the Western University of Pennsylvania, now the University of Pittsburgh, entered the field to furnish higher education for the young men. George Washington made a visit during this period in the interest of his lands which he owned here, and he found Semple's Tavern a very good place in which to stay. The Indian trader and agent, George Croghan, living here and engaged in peace missions or in pushing trade as far as the Illinois country, entertained Washington on this his last visit, 1770. Title to this part of Pennsylvania was in dispute between the Penns and Virginia, and in 1774 Lord Dunmore of Virginia took possession of Fort Pitt. Pittsburgh was then in Westmoreland County, and for a time two rival jurisdictions existed. Dunmore's agent was forced to flee, and command of the fort passed to Captain John Neville, a Virginian but not a Tory, the same Neville whose house was burned during the Whiskey Insurrection. He was succeeded by General Hand of the Continental army. The story of Revolutionary times is one of gathering men and supplies into the fort for expeditions against the Indians. This way came George Rogers Clark recruiting men, and down the river went expeditions led by General Harmar and Arthur St. Clair. Also passed the *Mayflower* bearing the first settlers of Ohio to Marietta, the year that Allegheny County was set up, 1788. The old fort had fallen into ruin after the Revolution, and a new one was later built some distance away on the Allegheny River side. Here came General Wayne to outfit his expedition, and make camp at the old Indian Logtown some 20 miles down the Ohio. His success opened up the real era of western settlement.

A post-office was opened, trade and commerce were established and a public celebration in honor of the new United States Constitution was held, all before 1790. The population, which was steadily increasing, was largely of English and Scotch-Irish stock. Soon afterward the Germans came in large numbers.

The idea of making articles for sale was taking form in the minds of the men. The opportunity for trade down the Ohio river promised to be very extensive and, with this in mind, there was started a series of manufactures that were to grow and develop to such an extent that 100 years later Pittsburgh was known as the «Workshop of the World.» One of the first and most ambitious enterprises started was glass making, instituted by two of the most enterprising citizens, Major Isaac Craig and General James O'Hara. It was O'Hara who established an elaborate system of salt transport extending from the salines near Syracuse, N. Y., to Pittsburgh, greatly reducing the price of this prime need of the settler. Skilled workers came from European countries and the glass produced ranged from the finest to the most practical. Due to the abundance of coal in nearby regions, the metal industries were soon started. Coal had been discovered in the bluffs of Mt. Washington, the famous "Pittsburgh Seam," and used by English soldiers at the old fort. The foundries of Pittsburgh were put to work. But the making of primary iron was done in the surrounding country. Attempt to remedy this by erecting a blast furnace, in what is now the Shadyside district of Pittsburgh, in 1792 failed because the iron ore was not conveniently at hand, and it was over half a century before the city was again an iron maker. But the iron masters of the back country sent much of their production into the town, and followed early the next century to set up rolling mills to fashion the iron into shapes. Pittsburgh at this early time made nails and wire, and rods which the blacksmith needed. One of the "lost industries" was the making of rope. These with the smaller crafts, such as leather and cabinet making and whiskey distilling, provided the chief occupations. The whiskey distilling was so profitable that when the United States Congress passed a bill placing an excise-tax on distilled spirits, there was an open revolt on the part of those who had to pay. This was the first organized defiance the new and untried Federal Government had experienced. It was taken very seriously and a detachment of soldiers was sent to Pittsburgh to suppress the Whiskey Insurrection, as it was called. The frontier town was honored with a visit from Alexander Hamilton, who assisted in the investigation.

In 1794 a charter for a borough was granted. By 1800 a new industry—boat-building—was started and it flourished for years. Interesting information on industries was a part of the series of Cramer almanacs. Many well-known travelers stopped here, to continue on their way south, down the Ohio river, after obtaining a flat-boat, keel-boat or some other type that was built here. Among them were Henri Collot (the French general), Aaron Burr, Meriwether Lewis, Andrew Jackson and Vincent Nolte, the friend of «Anthony Adverse.» The migration to the west increased continually, bringing additional activities to this rapidly growing town, which soon grew into a city. In 1813 the first steamboat on western waters, the *New Orleans,* was launched at Pittsburgh. The building of steamboats became a major enterprise in the district, and brought the engine shops to great activity. Before long the city had one of Oliver Evans' steam-power flour mills. The two rivers were bridged about 1818. By 1816 a charter was granted for the new form of government.

In 1825 Pittsburgh had its first formal public celebration. Upon the arrival of General Lafayette, who was making a tour of the nation, the city planned a royal welcome, which proved a great success. The next year on the 4th of July another large public celebration was held to commemorate the 50th anniversary of the United States. While this celebration was in progress, Stephen Foster, the famous song writer, was born.

A stage coach line had been established between Pittsburgh and Philadelphia for a number of years, and now another step in the

march of progress took place. By 1830 the Pennsylvania Canal was built and in full operation. One of the innovations of the canal was the use of wire rope, made by George A. Roebling from wire manufactured in Pittsburgh. He designed the city's first suspension bridge, built 1845–46. Among early visitors to the smoky city of this period was Mrs. Ann Royall, who described the scene. Charles Dickens traveled to Pittsburgh by canal. An early history of Pittsburgh was written by Neville Craig, newspaper publisher. Canals had a short life, as the railroads were the next step in advancement and made the canals practically useless. The Pennsylvania Central railroad, pushing west over much of the canal route, reached Pittsburgh in 1852. A railroad had already been opened, in 1851, down the right bank of the Ohio to the Beaver Valley. Slack-water navigation on the Monongahela had made a beginning with the building of some dams. The railroads were built in time to bring delegates to Pittsburgh to organize the Republican party, which was founded here in 1856. President-elect Lincoln, the party's first president, stopped here for a short visit on his way to be inaugurated.

History. Later period 1860–1940.—The decade following was one of great industrial expansion for Pittsburgh. The blast furnace had been successfully established at the end of the preceding period. More dependable supplies of iron ore began to arrive from the Lake Superior region. Connellsville coke replaced charcoal and raw coal as furnace fuel. Among Pittsburghers who were pioneers in the Lake Superior region were Dr. Curtis Hussey, crucible steel manufacturer, who erected a copper smelter in the city, and the Olivers, iron and steel manufacturers, who acquired large ore deposits and were foremost in the development of realty in the Golden Triangle. Locomotive works were established early in this period. Iron and steel in its massive forms, through the combination of Pittsburgh coal and Connellsville coke, found little rivalry outside this area for a half-century. The industries that were established were greatly enlarged and many new ones started, and their value was counted in the millions. This development was greatly enhanced by the commercial use of the oil resources, which was to become in time a tremendous industry. Pittsburgh had at last become a great industrial centre and some of the largest fortunes of the century were founded here at this time. The Civil War was keenly felt. In addition to men, guns and ships furnished by the city, there was an arsenal here which was an important source of munitions supply, and which employed many girls. A terrific explosion occurred 17 Sept. 1862 killing many of the workers. A pleasant event was the holding of a large, charitable ball, called the Sanitary Fair, which was a great financial and social success. The money was to help finance the war.

The next decade, from the 1870's to the 80's, was full of turmoil and hard times. Bank failures and a serious railroad strike and riots were dark spots in this period, culminating in the burning of the Union railroad station and wide destruction in July 1877. But from that time to the end of the century was another era of prosperity. The industries and the natural resources of oil and gas were fully utilized, and Pittsburgh was again a thriving centre. The building of the Edgar Thomson Steel Works by Andrew Carnegie and his associates in the early seventies marked a new era of industrial development—the beginning of large-scale and more highly technical operations. The works include blast furnaces and rolling mills. Rails were the principal product in this era of railroad building. Other works built or owned by the Carnegie interests included the Homestead Steel Works and Carrie furnaces, Union Mills, and Lucy furnaces, and the Duquesne Steel Works. The Homestead Works are noted for their open-hearth furnaces. Among Mr. Carnegie's partners were William Coleman, Henry Phipps, and Henry C. Frick. Identified with operations were Capt. W. R. (Bill) Jones, in charge of the Edgar Thomson Works, and Charles M. Schwab, who succeeded Frick at the Homestead Works after the strike. The various interests were consolidated into the Carnegie Steel Company, Ltd. in 1892. Carnegie also early entered into the bridge-building industry, and his bridges were famous for standing. In 1901 the Carnegie iron and steel interests were sold, forming the nucleus of the United States Steel Corporation. The American Federation of Labor held its first convention in Pittsburgh in 1881. Civic pride made itself felt and new wide streets and parks were planned, a new court house, fine new churches, schools, skyscrapers and elaborate homes were built and charitable institutions provided for. The citizens were called upon and responded generously to help after the Johnstown flood.

Andrew Carnegie, mindful of his early days in Pittsburgh and his gratitude to a friend for the free use of books, started the Civic Center in 1895 by providing a Library, Music Hall and Museum and Art Galleries. An international exhibition of paintings was opened, a symphony orchestra was formed, an annual industrial exposition was held and social life took on a new importance. At this time one of the worst industrial strikes of all times took place at the Homestead steel mills.

In 1936 Pittsburgh experienced the most disastrous flood in its entire history. The business section was under water, the power plants were completely flooded and transportation was at a standstill for several days. The property loss amounted to millions of dollars. To prevent a recurrence of this calamity, a definite program of flood control was started. The plan, as developed, calls for a series of reservoirs which extend from the upper Allegheny Reservoir in the northern part of the State to the Tygart River Reservoir in West Virginia south of the State. The great metropolitan district of which Pittsburgh is the centre is constantly growing, not only in population, but also in industrial and educational and cultural traditions.

PITTSBURGH, University of. The University was first chartered 28 Feb. 1787 as the Pittsburgh Academy, one of the oldest chartered institutions of higher learning west of the Allegheny Mountains and north of the Ohio River. In February 1819, the university received a second charter under the name, Western University of Pennsylvania. Through this charter it inherited the Pittsburgh Academy property and was given power to grant baccalaureate degrees. This charter also established for the university privileges of State aid similar to those granted to the other University of Pennsylvania, east of the mountains. The University of Pittsburgh receives, currently, 25 per cent of its maintenance from the Commonwealth. In 1908, through permission of the courts, the name was changed to University of Pittsburgh.

The university gave its first degrees in 1823. Engineering courses were offered and law degrees were granted early in the 1840's. In 1865, through legislative act, the Allegheny Observatory was conveyed to the university. Here Samuel P. Langley, distinguished for solar research and for early experiments in the science of aeronautics, James E. Keeler, who discovered the moons of Saturn, and other prominent astrophysicists and astronomers have conducted research that has made the University of Pittsburgh's Allegheny Observatory known over the world.

Beginning with 1892, several schools have been added to the university's curriculum, granting the customary undergraduate and graduate degrees: School of Medicine, 1892; School of Law, 1895; School of Mines, established in 1895 by legislative act; schools of Dentistry and of Pharmacy, 1896; School of Economics, 1910 (since 1923, the School of Business Administration); School of Education, 1910; Graduate School, 1912 (although graduate courses and graduate degrees had been offered in the 1880's in liberal arts and in science); Summer Session and Evening School, 1907; Extension Division, 1913; Mellon Institute for Industrial Research, 1913; Research Bureau for Retail Training, 1918; Falk School, a progressive school for elementary education, 1931; School of Applied Social Sciences, 1938; and School of Nursing, 1939.

The university maintains at Erie and at Johnstown, Pa., extension centres for junior college training. About 1,000 students are enrolled in these centres.

The university, offering the usual degrees, undergraduate and graduate, has been co-educational in all of its schools and departments since 1895.

A dramatic impulse to the growth of the university was begun in 1921 by the then newly elected and present chancellor, John G. Bowman. There was immediate need at that time for additional space of 13,000,000 cubic feet. A 42-story building, the Cathedral of Learning, was erected by public subscription on the centre of a 14-acre plot in the civic centre of Pittsburgh. This building houses the university's libraries, including one of the finest libraries of fine arts and one of the finest libraries of Americana in existence; 91 classrooms; 67 undergraduate laboratories; 52 research laboratories; 13 large lecture rooms; 15 departmental studies; 78 offices; a faculty club; and several student lounges, lunchrooms, and recreation centres. Eight elevators carry about 20 students per trip to classrooms, laboratories, and libraries. Over 14,000 students enrolled in the University of Pittsburgh in 1939. 12,500 of them daily use the Cathedral of Learning. The teaching staff numbers about 600.

The Schools of Engineering and of Mines and the professional schools of Medicine and Dentistry occupy the older buildings of the university on the hillside campus. Adjoining the professional schools is the University's Medical Centre, its hospitals, clinics, and scientific laboratories. This Medical Centre when completed will be one of the finest in the world. The Children's Hospital, the Eye and Ear Hospital, the Elizabeth Steel Magee Hospital, Woman's Hospital, Presbyterian General, Western State Psychiatric, Falk Clinic, and the City Hospital for Infectious Diseases are members of the Medical Centre and occupy fine new buildings adjacent to the campus.

The principal gathering place for students is the Commons Room on the first floor of the Cathedral of Learning. Its floor space covers about half an acre. Gothic arches rise 60 feet to a vaulted ceiling. Around the Commons Room, doors open from a corridor into 10 nationality classrooms. Seven more are being built. These rooms represent in design, material, and furnishing, to the last detail, what the several nationalities which make up the population of Pittsburgh hold precious in their heritages. About 3,000 visitors weekly come to the university from all over the world.

The Heinz Memorial Chapel, 13th century Gothic, is a student chapel, nonsectarian, with 23 stained glass windows picturing men and women from the Bible, from scientific learning, from literature, from art, from education, and from history, whose lives throughout the ages have exemplified human nobility.

The Stephen Collins Foster Memorial, also Gothic in structure, is the largest memorial anywhere to a musician. Its shrine houses the most complete collection of Fosteriana in the world, given in trust to the university for the people of the nation. It also contains auditoriums, assembly rooms, and a stage and dressing rooms which are laboratories for play conducting. It is a fitting memorial to Pittsburgh's Stephen Foster, whose songs are sung around the world.

The value of university buildings, exclusive of the hospital buildings, is $13,669,102; of equipment, $1,478,973; of libraries, $1,185,130. The total plant value, not including the value of the hospital buildings, their libraries, and equipment, is $17,333,205.

The buildings on the Cathedral of Learning campus are all built by public gifts. They express an educational philosophy for which beautiful surroundings, honest research, and sound teaching are the core.

PITTSBURGH LANDING, Battle of. A battle of the Civil War fought 6 and 7 April 1862 at Pittsburgh Landing in Tennessee, on the west bank of the Tennessee River, about 20 miles north of Corinth, Miss. See SHILOH, BATTLE OF.

PITTSFIELD, Me., town in Somerset County; alt. 210 feet; on the Sebasticook River; and the Maine Central Railroad; 101m. NE. of Portland. It is the trading center of an agricultural section, and has shoe and textile factories. Maine Central Institute is located here. Pittsfield is governed by selectmen and a town agent. Pop. (1940) 3,329.

PITTSFIELD, Mass., city and Berkshire County seat; alt. 1,038 feet; on the Housatonic River; and on the Boston and Albany, and the New York, New Haven and Hartford railroads, 52m. NW. of Springfield; has an airport. Pittsfield, in the Berkshire Hills, is a summer and winter resort; but it also has a considerable activity in the field of industry. Its mills and factories produce paper, plastics, textiles, and electrical machinery. In addition to its residential, recreational, and industrial phases, Pittsfield has excellent cultural features. Both public and parochial schools systems include secondary and elementary schools. The public library is called the Athenaeum. In near-by towns of the county are Little Theaters, schools of drama, and a music temple, where the Boston Symphony concerts are held each summer. The Berkshire Museum of Natural History and Art has notable collections in both departments. Pittsfield has interesting associations with the literary history of the United States: Holmesdale, on Holmes Road, was for some years the summer home of Oliver Wendell Holmes (q.v.); Arrowhead, further out on the same road, was the home of Herman Melville (q.v.), where he wrote 'Moby Dick' and other books. The Walton Wild Acres Sanctuary and the Pittsfield State Forest are points of interest for lovers of nature and the outdoors; in the state forest there are ski trails. First settlement on the site of the present city was made in 1743, and was known as Pontoosuc Plantation; it was abandoned because of Indian attacks, and was resettled in 1752. For many decades Pittsfield was an agricultural center; after the Revolution and the War of 1812 it turned more and more to industry, especially textile milling and paper making. From 1900 to 1910 its population increased by more than 40 per cent. Pittsfield was incorporated as a town in 1761; as a city in 1891. It has mayor and council; the water supply system is city-owned. Pop. (1930) 49,677; (1940) 49,684.

PITTSTON, Pa., city in Luzerne County; alt. 570 feet; on the Susquehanna River; on the Central of New Jersey; Delaware and Hudson; Delaware, Lackawanna and Western; Lehigh Valley; and Erie railroads; 8m. NE. of Wilkes-Barre. It is served by the Wilkes-Barre Wyoming Valley airport, with airline service. There is farming in the county, but the city's environment is predominantly industrial. Pittston is situated in the anthracite region, and there are deposits of fire clay near by. Coal mining is the leading industry followed by stove manufacture, silk making, and the manufacture of wrapping paper and waxed paper. Mine supplies and machinery are made here, and there are brick works and railroad shops. The city hall, hospital, and St. John the Evangelist Church are the more notable buildings. Public and parochial school systems include both elementary and high schools. There is a public library; also, a community theater. A monument commemorates the battle and massacre of Wyoming, July 1778. (See WYOMING VALLEY.) The name Pittston was adopted in honor of the elder William Pitt, British statesman and friend of the colonies. Historic sites are those of Fort Pittston in the city, and of Fort Jenkins in West Pittston; they typify the history of central and western Pennsylvania in pre-Revolutionary times. Pittston and several other Wyoming Valley towns were settled by colonists from Connecticut; and Pennsylvania and Connecticut disputed title to this territory, long and bitterly. Pittston, first settled about 1762, was incorporated as a borough in 1853, and chartered as a city in 1894. It has a mayor and council. Dial Rock overlooks the city on the north. There is a legend that early settlers could tell the time of day by the position of sun shadows on the rock. Pop. (1940) 17,828.

PITUITARY BODY or **GLAND** (*Hypophysis cerebri*), a small oval, reddish-gray, vascular mass lodged in a depression (pituitary fossa or cella turcica) of the sphenoid bone, and connected with the brain by a pedicel. In man it is about the size of an ordinary pea. It has two lobes, each of which has a special function. When the forward lobe is overactive, the body is built up into gigantic form, known as giantism. Diminished activity is expressed in various anomalies and mental defects. From the pituitary bodies of oxen a «pituitary extract» has been made, and two hormones have been separated from the posterior lobe with actions relieving the pangs of childbirth, and diabetes. See Cushing, H., 'Studies in Intercranial Physiology.'

PITYRIASIS, an affection of the skin (*pityriasis simplex*), characterized by a scurfiness of the epidermis with numerous branny scales. It is also a symptom of various skin diseases attended by accumulations upon the surface of the body of oily, waxy or bran-like scales. *Pityriasis capitis* (dandruff), beginning as a mild affection, may become a part of *dermatitis seborrhoica,* an inflammation of the derma of the scalp; lichen piliaris (*pityriasis rosea*) is a hypertrophic disease with conical elevations of sebaceous material and epithelial cells about the orifices of hair-follicles; *pityriasis rubra* is an inflammatory disease of the entire skin with abundant thin white scales. The favorite seats of pityriasis are the scalp, face, back, chest, umbilicus and the genital organs, but it may involve the whole body. Though usually a mild affection, it may be severe and last for months. In many cases there is little inflammation, the skin being pale and either dry or greasy. Pityriasis occurs especially in anæmic and chlorotic individuals, and is often increased by care, anxiety or dissipation. Treatment calls for tonics, attention to hygienic measures and the application locally of fatty substances, especially stimulating ointments. In pityriasis of the face exposure to cold winds is often irritating; therefore, before going into the open air apply a soothing lotion. Consult Kaposi, 'Pathology and Treatment of Diseases of the Skin' (1895) and Pusey, William Allen (in 'Reference Handbook of the Medical Sciences,' Vol. VII, New York 1916).

PITZER, Alexander White, American clergyman: b. Salem, Va., 14 Sept. 1834; d. 22 July 1927. He was educated at the Virginia

Collegiate Institute (Roanoke College) and at Hampden-Sidney College; studied theology at the Union Theological Seminary and at Danville, Ky., and began preaching at Leavenworth, Kan., in 1857. From 1858–61 he was pastor of the First Church there, when he returned to Virginia and served as missionary to the Confederate armies. Subsequently he held pastorates at Sparta and Mount Zion, Ga., Cave Spring and Liberty, Va., until 1867, when he undertook evangelistic work at Washington, D. C. Here he organized the Central Church in 1868, and was its pastor. He was a supporter of the pre-millenial theory of the coming of Christ, also an ardent advocate of the Revisionist movement. His works include: 'Ecce Deus Homo'; 'Christ the Teacher of Men'; 'The New Life'; 'Confidence in Christ'; 'Manifold Ministry of the Holy Spirit'; 'Predestination,' and 'Blessed Hope of the Lord's Return.' He contributed also to numerous journals.

PIURA, pē-oo'rä, a river, department or province, and city of northern Peru. (1) Rio de Piura, or Sechura, rises in the coast cordillera scarcely 100 miles from where it empties into the Pacific at a point nearly due west from its source, but by its great sweep to the north around the Sechura Desert makes its actual length nearly 200 miles. It is called Huarmaca in its upper course, and near Sechura Bay and below Sechura Desert is named the Sechura. It is navigable from February to June. (2) The department, in the extreme northwestern corner of Peru is mountainous in the north and east and a great desert in the south. Its area is 15,240 square miles. The Piura valley is one of the chief cotton-growing centres helped out by irrigation. Cotton-seed oil is made in the factories, which also press 20,000 gals. of castor oil annually. Stock raising prospers in the rich mountain pastures. Petroleum is found in large quantities, and is the largest export. Pop. about 220,000. (3) The capital city of the department, 550 miles northwest of Lima, and 80 miles southeast of Cape Blanco, on the western bank of the river, is connected by rail with Paita, its harbor, which has a population of 4,000. The surrounding country grows a fine grade of cotton. The manufactures are Panama hats, soap and candles, and lumber. It is a trade centre for the northern valleys of Peru and southern Ecuador. There is a chamber of commerce, two banks, and bank agencies. Pop. (estimated) 15,000.

PIUS, pī'ŭs, the name of 11 popes, as follows:

Pius I, Saint: d. 155. Little more is known of him than that he succeeded Hyginus about 140, and died about 154. His day is 11 July.

Pius II (Æneas Sylvius Piccolomini, ē-nē'as sĭl'vĭ-ŭs pĭk-kō-lŏm'ē-nē): b. Corsignano, near Siena, 18 Oct. 1405; d. Ancona, 14 Aug. 1464. He belonged to an illustrious family and in 1431 assisted at the Council at Basel as secretary. He was subsequently secretary to the antipope Felix V, and then to the Emperor Frederick III, by whom he was employed on various embassies. Eugenius IV made him apostolic secretary and by Nicholas V he was made bishop of Trieste in 1447 and sent as nuncio to Bohemia, Moravia and Silesia. He became bishop of Siena in 1449 and Calixtus III created him cardinal 18 Dec. 1456. Early in his career he was a liberal in ecclesiastical matters, but he now became a staunch upholder of papal authority both in opposition to the secular power and to the authority of councils. He was one of the most learned men of his day and distinguished by moderation and a conciliatory spirit. He succeeded Calixtus III 19 Aug. 1458, and in the next year assembled a congress at Mantua to plan a crusade against the Turks, but nothing of importance was then accomplished. He is best known at the present day by his writings, and as author and scholar furnishes an excellent example of the learning of the Renaissance. His works include 'History of Bohemia'; 'Cosmographia'; 'History of the Council of Basel'; 'History of Frederick III,' etc. Consult Lives by Voigt (1856-63) and Weiss (1897); Creighton, 'Historical Essays and Reviews' (1902).

Pius III (Francesco Todeschini, fränchĕs'kō tō-dĕs-kē'nē): b. Siena, 29 May 1439; d. 18 Oct. 1503. He was a nephew of Pius II, by whom he was made bishop of Siena and subsequently cardinal. He was elected Pope in succession to Alexander VI on 22 Sept. 1503, but died only 26 days afterward.

Pius IV (Giovanni Angelo de' Medici, jō-vän'nē än'jā-lō dā mā'dē-chē): b. Milan, 31 March 1499; d. 9 Dec. 1565. He studied medicine and law, but subsequently entered the Church and was made an archbishop in 1545 and cardinal in 1549. Ten years later (26 Dec. 1559) he succeeded Paul IV in the papal chair. The most important event of his pontificate was the reopening of the Council of Trent. In 1564 he published a bull confirming the decrees of this council. The confession of faith known as the Creed of Pius IV (q.v.) was put forth by him as a statement of the dogmas defined in the council.

Pius V, Saint (Michele Ghislieri, mē-kā-lā gēs-lē-ā'rē): b. Bosco, near Alessandria, Italy, 17 Jan 1504; d. 1 May 1572. He entered the Dominican Order at 14 and was so distinguished by austerity of his life, and his zeal against heresy, that he was appointed inquisitor in Lombardy, and in 1558 inquisitor-general. He was created cardinal in 1557, and succeeded Pius IV, 7 Jan. 1566. He at once began to enforce reforms with great vigor and aroused much opposition by his seizure, imprisonment and burning of persons convicted or suspected of heresy, among whom were several men of note. He reissued the bull, "In cœnam Domini," and expelled the Jews from the states of the Church, excepting only the cities of Rome and Ancona. The victory over the Turks at Lepanto was largely the result of the efforts of Pius V, who organized with Venice and Spain the Holy League against them. He was canonized in 1712. Consult Falloux, 'Histoire de Saint Pie V' (3d ed., 1858).

Pius VI (Giovanni Angelico Braschi, jō-vän'nē än'jāl-ē kō bräs'kē): b. Cesena, Italy, 27 Dec. 1717; d. Valence, France, 29 Aug. 1799. He was made a cardinal in 1773 and succeeded Clement XIV 15 Feb. 1775. He immediately instituted reforms in the public treasury, and next completed the museum in the Vatican, but his greatest work was the draining of the Pontine marshes. When the Austrian emperor, Joseph II, decreed that all the religious orders

in his dominions were free from papal jurisdiction, Pius, apprehensive of the consequences of such a measure, went in person to Vienna in 1782, but his remonstrances were futile. At the time of the French Revolution the Pope having favored the allies, Bonaparte entered the papal dominions and compelled him to purchase a peace. Basseville, an agent of the republic to Rome, aroused so much hatred that he was presently slain by the populace. The French forces under Duphot attempted to restore order, but the papal soldiers routed them, and Duphot was slain. Bonaparte accordingly entered Italy, made the Pope prisoner and plundered the city. The aged Pontiff was then carried away by the victors, and hurried over the Alps to Valence, where he died.

Pius VII (Gregorio Barnaba Chiaramonti, grā-gō'rē-ō bär'nä-bä kē-ä-rä-mōn'tē): b. Cesna, Italy, 14 Aug. 1740; d. 20 Aug. 1823. He was a Benedictine monk who became bishop of Tivoli and was created cardinal in 1785. He succeeded Pius VI 14 March 1800 and the next year concluded at Paris a concordat with France. In 1804 he went to Paris and crowned Napoleon emperor, but after the seizure of Ancona the quarrel between Napoleon and the Pope began. On the annexation of the states of the Church to the French Empire in 1809 the Pope published a bull of excommunication against the perpetrators of the invasion. He was then arrested and sent to Savona, and afterward to Fontainebleau, and was not permitted to return to Italy until January 1814. The Congress of Vienna restored the states of the Church to the Pope, who applied himself thenceforth to internal reforms. He re-established the Order of the Jesuits in the year of his return to Rome. The character of Pius VII was such as to win him the esteem and sympathy of men of views the most diverse. Consult Artaud, 'Histoire du Pape Pie VII' (1836); Celani, 'Il Viaggio di Pio VII a Parigi' (1893) and 'Life' by Allies (1901).

Pius VIII (Francesco Xaviero Castiglione, frän-chĕs'kō zä-vē-ā'rō käs-tēl-yō-nā): b. Cingoli, near Ancona, Italy, 20 Nov. 1761; d. Rome, 1 Dec. 1830. After being successively bishop of Montalto, Cesena and Frascati, he became cardinal in 1816 and Pope in succession to Leo XII, 31 March 1829. During his short pontificate of one year he condemned the slave trade in Brazil, opposed civil marriages in Prussia, denounced Freemasonry and secured the organization of an Armenian archbishopric at Constantinople. Consult Artaud, 'Histoire du Pape Pie VIII' (1844).

Pius IX (Giovanni Maria Mastai-Ferretti, jō-vän'nē mä-rē'ä mäs'tä-ē-fĕr-rĕt'tē): b. Sinigaglia, 13 May 1792; d. Rome, 7 Feb. 1878. He belonged to a noble Lombard family. He was educated at the College of Volterra, and in 1815 became one of the Guardia Nobile of the Vatican, but soon after entered the Church, and lived for a few years in Rome as the head of a large orphanage. Not long after the death, in 1823, of Pius VII he was appointed by Leo XII a prelate in his household; in 1827 was created archbishop of Spoleto, and five years later transferred to the see of Imola. At Imola he showed himself zealous in good works and possessed of liberal convictions. He was raised to the cardinalate in December 1840, but continued to reside in his diocese till 1846, when, shortly after the death of Gregory XVI he was elected Pope, 16 June. In honor of his patron, Pius VII, he assumed the name of Pius IX (Pio Nono). He ushered in his reign by liberating 2,000 political offenders imprisoned by his predecessors, and granted a general amnesty, restoring all prisoners and exiles to their civil rights on their signing a declaration of allegiance. He also established four new dioceses in the United States at Albany, Buffalo, Cleveland and Galveston, all in 1847. In later years he established nearly 50 others in medium-sized American cities. He also (in 1848) drew up a scheme of representative government, with two chambers, a free press and a national guard. These and similar measures for a brief period secured him boundless popularity. But the Italians wished to drive out the Austrians. The Milanese overpowered Radetzky, Charles Albert led the Piedmontese to the Minico, and the youth of all Italy rose to the rescue. Matters were now going too fast and too far for Pius, who refused to countenance the revolutionary movement, and as a result Charles Albert was overpowered in Lombardy, while Naples, Tuscany, Parma and Modena had their newly-acquired freedom quenched in blood. The Pope now entirely lost the favor of the Roman populace. Threatened by the mob in his own palace he fled to Gaeta, and a Roman republic was proclaimed in February 1849, with Mazzini at its head. Louis Napoleon, determined to restore the Pope, sent an expedition to Rome under Oudinot, by whom the Italian patriots, led by Garibaldi, were overpowered. Rome surrendered on 3 July; but the Pope did not return to his capital till April 1850. After his return his government lost much of its personal character, and became reactionary. He now placed his whole confidence in Antonelli, a prelate who had risen to distinction under Gregory XVI and whom Pius had made a cardinal and a member of his council of state in 1847. Antonelli preserved the ascendency in all matters of state till his death in 1876. The Pope himself now bestowed his whole attention upon the Church. He recalled the Jesuits, canonized saints and defined two dogmas. The doctrine of the immaculate conception of the Virgin Mary was defined in 1854; that of the infallibility of the Pope, when speaking *ex cathedra* on a question of faith or morals, was proclaimed in the great Ecumenical Council held in the Vatican in 1870. Previous to this time the Pope's temporal dominions had become sadly shrunken in extent, owing to the gradual unification of Italy under Victor Emmanuel. (See Italy). The temporal power of the Pope, however, was still secured by the presence of a body of French troops at Rome. But after the defeat of Napoleon III at Sedan these were withdrawn. On 20 Sept. 1870 the Italian troops entered Rome, and the temporal power was at an end. The Vatican was left to the Pope; and free diplomatic intercourse, the honors due to a sovereign, and a civil list of £129,000 yearly, secured to him. But these he declined, and confined himself to the Vatican and its garden, declaring that he was under restraint and a prisoner in his own palace. Consult Pougeois, 'Histoire de

Pie IX' (1877–86) and Lives by Maguire (1878); Shea (1878); O'Reilly.

Pius X (Giuseppe Sarto, joo-sĕp'pā sär'to) Pope (1903–14): b. Riese, near Venice, 2 June 1835; d. 20 Aug. 1914. He was of humble peasant parentage. His father died 4 March 1842; his mother, Margarita Sanson, 2 Feb. 1894. He was one of nine children. His elementary studies were made at Castelfranco, not far from Venice, and he studied theology at the seminaries of Treviso and Padua. He was ordained to the priesthood 18 Sept. 1858 and appointed assistant priest at Tombolo, from which place he was transferred in 1867 to Salsano as parish priest. In 1875 he was made spiritual director in the seminary, judge of the ecclesiastical tribunal, and vicar-general of Treviso. After refusing the bishopric of Treviso in 1880, he was consecrated bishop of Mantua, in Lombardy, in 1884. On 12 June 1893, Pope Leo XIII created him cardinal with San Bernardo alle Terme as his titular church. Three days later he was made Patriarch of Venice. Ten years thereafter he was called to Rome to assist in the election of a successor to Pope Leo XIII, who died 20 July 1903, and was himself elected to the papal throne on 4 Aug. 1903 after the conclave had been in session five days. His elevation to the papacy was a striking example of the bestowal of the highest dignity in the Roman Catholic Church upon one of the humblest origin, who was utterly void of ambition and whose career had been marked only by the sincerest piety and indomitable zeal.

As Pope he exacted observance of discipline, although he was indifferent to ceremony. He was a staunch advocate of the Gregorian chant which was in keeping with his insistence on liturgical observance. In his first encyclical issued two months after his accession, he declared that "we have no other program in the Supreme Pontificate but that of restoring all things in Christ" (Eph. 10). Shortly after his elevation to the papacy, Pius X abolished the "veto" which three Catholic powers claimed the right to exercise in the election of a Pope and which was exercised for the last time (by Austria) against Cardinal Rampolla in the conclave which elected Pius X. Pius X displayed great restraint when relations between the Church and the French government were severed. In 1907 he issued the encyclical "Pascendi" condemning modernism. He advocated greater study of the Bible and appointed commissions to revise the Vulgate and to codify the canon law. The outbreak of the World War in 1914 is believed to have hastened his death. Consult 'Life of Pope Pius X,' with preface by Cardinal Gibbons (New York 1904); Giacomello, 'Pio X' (Padua 1908).

Pius XI (Achille Ratti) Pope (1922–39): b. Desio, 31 March 1857; d. 10 Feb. 1939. His father, Francesco Ratti, a native of Rogeno, was a weaver of the respectable middle class. His mother was Teresa Galli, a native of Savonno. He was the third of six children, of whom, Fermo, his oldest brother, and Camilla, his youngest sister, were living at the time of his elevation to the papacy. After early studies under Don Giuseppe Volonteri at Desio, the future Pope attended successively the gymnasium of Saint Peter Martyr, the lyceum in the Seminary of Monza, and the College of Saint Charles Borromeo, Milan. He next attended the Grand Seminary of Milan and made such an impression upon the archbishop that the latter sent him to Rome where he completed his course at the Lombard College, obtaining at the Gregorian University doctorates in philosophy, theology and canon law. He was ordained priest in 1879 and celebrated his first mass over the tomb of Saint Peter at the Vatican. Returning to Milan in 1882, he taught theology and sacred eloquence in the Grand Seminary until 1888, when, on 5 October, he was chosen one of the staff of the College of Doctors of the world-famed Ambrosian Library. Nearly 20 years of his life were devoted to work in this library. During the same period he was also zealous in pastoral work. When Monsignor Ceriani, prefect of the Ambrosian Library, died in March 1907, Monsignor Ratti succeeded him. He continued at this post until 1914 but in 1910 was called to Rome by Pope Pius X to become vice-prefect of the Vatican Library and assistant to Father Ehrle. When the latter resigned in 1914 at the outbreak of the World War and returned to his native Germany, Monsignor Ratti was chosen as his successor and soon afterward severed his connection with the Ambrosian Library. He served as prefect of the Vatican Library from 1914 until the spring of 1918 when he was delegated by Pope Benedict XV as Apostolic Visitor to Poland. Monsignor Ratti started for Warsaw, 25 April 1918, on what was known in advance to be a hard diplomatic and ecclesiastical mission. So well did he discharge his duties that his mission was extended to embrace the Catholic interests of all the regions formerly belonging to the Russian empire. The logical sequel to his success was his appointment, 13 June 1919, as Apostolic Nuncio to the new Republic of Poland. As nuncio he was eminently successful at a time that called for the utmost discretion, and in a state that was one of the active storm centres of Europe. By his tact and unflinching courage Monsignor Ratti helped in a great measure to solve the delicate problem. Chiefly as a result of his efforts two articles were written into the Polish constitution, one declaring that the Catholic religion occupies first place in the state, and the other providing that no action can be taken by the state relative to the property of the Catholic Church without a preliminary agreement being made with the Holy See. During the Bolshevist invasion of 1920, Monsignor Ratti stood at his post and inspired others to do likewise. He was active in the relief of prisoners of war and aided in the distribution of food among the children of the Russian and Polish populations.

On 3 July 1920 he was made titular archbishop of Lepanto; in April 1921 he was made archbishop of Milan and on 13 June 1921 he was created cardinal. Following the death of Pope Benedict XV on 22 Jan. 1922, Cardinal Ratti was chosen his successor on 6 Feb. 1922 and was crowned 12 February following.

His pontificate was one of the most notable in the history of the Church, particularly because of the negotiations by him which culminated, in 1929, in the historic Lateran treaties ending the 59-year estrangement between the Italian state and the Holy See and restoring temporal power to the Popes as rulers of Vatican City. In 1929 he established a modus vivendi with Mexico which eased the persecution of the Church in that country. A concor-

Acme

His Holiness Pope Pius XII

dat with Germany was signed 20 July 1933 but this did little to relieve the pressure on the church of the Hitler Nazi movement. During his reign, he wrote more than twenty encyclicals, a larger number than any other Pope. His later years were troubled with the persecution of the Church in Germany, and in Leftist Spain. The transplanting of racial intolerance to Italy by Mussolini caused a coolness between the Vatican and the Fascists. Pius XI added thirty to the canon of saints including Joan of Arc, Thomas More, and Bishop John Fisher.

PIUS XII (Eugenio Pacelli) Pope (1939—): b. Rome, 2 March 1876. His family belongs to the so-called «black» nobility—that is, the Papal nobility as distinguished from the «white» nobility, whose titles are derived from secular powers. The father of Pius XII was for many years dean of the College of Consistorial Advocates, or Vatican lawyers, and at the time of his election, three nephews were attached to the Vatican legal staff. His only brother Francesco was made a Papal marquis for his services in the settlement of the «Roman Question» in 1929. The future Pope's first teachers were nuns; later he attended the Lycée, being destined for his father's profession, the law. Announcing his intention of becoming a priest, he entered the Capranica Seminary and was ordained in 1899. His studies in diplomacy began at the Pontifical Academy, where he became professor of canon law. There he came under the notice of Cardinal Gasparri, then secretary of the Congregation for Extraordinary Ecclesiastical Affairs and later Secretary of State under Benedict XV and Pius XI, who directed him to devote his talents exclusively to the work of the Congregation for Extraordinary Ecclesiastical Affairs. Father Pacelli began as minutante, or copyist, and advanced to secretary of the Congregation. In 1912, when Cardinal Merry del Val was Secretary of State to Pius X, Father Pacelli was named under secretary. This position he held under Benedict XV and Gasparri until 20 April 1917 when he was named nuncio to Munich, having been just named Archbishop of Sardis. He was consecrated 13 May 1917. In the summer of 1917 he held important conversations with the German Chancellor Bethmann-Hollweg and at war field headquarters on the Western Front the Kaiser received from his hand a letter from Pope Benedict urging him to endeavor to restore peace to the world. The following August through Archbishop Pacelli the Pope made his attempt to mediate between the Central Powers and the Allies. Archbishop Pacelli remained in Munich during the troubled days after the war and concluded negotiations for a concordat with Bavaria. On 22 June 1920 he moved to Berlin as the first nuncio accredited to the German Republic and there on 14 June 1929 he won one of his greatest diplomatic victories, the arrangement of a successful concordat with the dominantly Protestant state of Prussia. On 16 Dec. 1929 he was created cardinal and recalled to Rome by Pius XI. There on 11 Feb. 1930 he was appointed Papal Secretary of State. In this post, the chief diplomat of the Church, he shared with the Pope some of the most serious and grievous problems in the long history of the Church—the spread of Communism and worldwide atheism, «pagan absolutism» in the totalitarian states, economic difficulties which strained the resources and institutions of the civilized world, an alarming re-growth of the war spirit, the curbing of Church activities in Mexico and the tragic involvement of religion in the civil war in Spain. Cardinal Pacelli was completely identified with the policy of Pope Pius XI in standing resolutely for the rights of the Church and her people in every land. As a result the relations with Germany grew more strained despite the concordat of 1933. Pius XI died on 10 Feb. 1939 and in the Conclave that followed Cardinal Pacelli, on 2 March, was chosen Pope on the third ballot and assumed the name of Pius XII. The new Pope is one of the most traveled of Catholic prelates. In 1911 he was a member of the Vatican delegation at the coronation of George V in London; in 1934 he was Papal Legate to the International Eucharistic Congress at Buenos Aires; in 1935 he represented Pius XI at Lourdes, France; and in 1936 he visited the United States, where he traveled extensively by air, visiting many of the leading cities of the country.

PIUTE, properly **PAIUTE** or **PAH UTE INDIANS**, a term applied at one time or another to most of the tribes of the Shoshoni group living in western Utah, northern Arizona, eastern Idaho, eastern Oregon, Nevada, and eastern and southern California. Certain of these tribes have also been called Paviotsos, Chemehuevis, Pautis and Numas. In 1906 there were 2,016 of them on reservations and about 5,000 scattered outside. They are strong, healthy, active people of good character, many of them working as laborers on the farms of white men. They have been increasing in numbers of late years. See SHOSHONEAN INDIANS.

PIZARRO, pĭ-zär'rō (Sp. pē-thär'rō), **Francisco**, Spanish adventurer, the discoverer and conqueror of Peru: b. Truxillo, Estremadura, about 1471; d. Lima, Peru, 26 June 1541. He came to Darien in 1509 and accompanied Balboa's expedition to the Pacific in 1513. Later, with Hernando Luque, a priest and Diego de Almagro, he joined in fitting out the expedition which sailed southward along the Pacific coast in 1524. During this voyage he learned of the rich empire of Peru, and returned to Spain to raise a sufficient force to attempt its conquest. With this and a commission from the queen of Spain according him the right of discovery and conquest and the title of governor and captain-general of the province to be captured, he recrossed the Atlantic in 1530, and in January 1531 sailed from Panama with three vessels and a force of 185. He joined one of the contestants in a civil war then raging in Peru, and made a prisoner of the successful combatant, Atahualapa, subsequently releasing him upon payment of $8,000,000 ransom. News of this success brought to Pizarro from Europe a large accession to his forces. The Inca Manco was permitted to reign as nominal monarch. Pizarro was made a marquis, and in 1535 established the city of Lima as capital of his possessions. Discord between Pizarro and Almagro eventually led to open warfare, in which Almagro was captured and killed, an event which was avenged by Almagro's partisans, who conspired against Pizarro and murdered him in his palace at Lima. The character of Pizarro has been largely rehabilitated by the new school of the historians of the Spanish

conquests. He is now acknowledged to have been not only a man of remarkable military genius, but of great integrity and high moral purpose. Consult Prescott, 'Conquest of Peru' (1847); Markham, 'Peru' (1893); Lummis, 'Spanish Pioneers' (1893); Ober, F. A., 'Pizarro, and the Conquest of Peru' (1906).

PIZARRO, Gonzalo, Spanish adventurer: b. Truxillo, Estremadura, about 1506; d. Cuzco, Peru, April 1548. He was half-brother of Francisco Pizarro (q.v.) whom he accompanied on a second visit to Peru in 1531. In early life he had signally distinguished himself as a soldier and when he reached the New World was acknowledged to be the best lance in Peru. His talents were exclusively those of a guerrilla chief, as he lacked the military and civil capacity of Francisco. After the assassination of Francisco, Gonzalo raised an army and advanced upon Lima to attack Nuñez Vela, the new and unpopular viceroy sent out from Spain. He was warmly supported by the bulk of the colonists and many of the royal troops. On 18 Jan. 1546 a battle took place at Anaquito near Quito, in which Nuñez was defeated and slain. But in the following year Pizarro was attacked by an army sent from Spain under Pedro de la Gasca and was eventually defeated, taken prisoner and executed.

PLACENTA. See Embryology, Obstetrics.

PLACER DEPOSITS, deposits of the metals or valuable minerals in fragmental form associated with coarse sand or gravel. The common minerals to be found in this way are gold, platinum, tin, chromium, iron, precious stones, and monazite, though other placer deposits are known. Magnetite is the commonest of the ores found in placers and the frequency of gold and platinum in it gives it a high commercial value. Placer deposits originate from the weathering of rocks in which these minerals occur. As the valuable minerals are heavier than the waste rock, they are gradually segregated by the carrying away of the finer or lighter material. The gold placers of California and Alaska constitute familiar examples. The valuable minerals are secured by washing the gravels either by hand (panning), sluicing, «dry washing,» or other means. See Gold Mining.

PLACERVILLE, Calif., a town, county-seat of Eldorado County, on the Camino, Placerville and Lake Tahoe Railroad, which connects with the Southern Pacific for Sacramento about 40 miles to the west. The town is also on the Lincoln Highway en route to Lake Tahoe, the most beautiful part of which lies in the county. As its name suggests, the town is associated in history with the days of '49. Gold mining is still carried on, and there are also slate quarries nearby. Dairying, lumbering, stock-raising and fruit-growing are important interests. Pop. (1940) 3,064.

PLACET, plā'sĕt, or **PLACITUM,** plăs'ĭ-tŭm (*placitum regium*), the assent of the civil power to the promulgation of pontifical ordinances within its jurisdiction; called also *exequatur.* The right to exercise supervision over communications of the Holy See with bishops, clergy and people of sovereign states and to prevent or suspend the promulgation of bulls, letters apostolic and other papal instruments, unless they have received the approval of the secular state itself, is asserted in the famous 'Declaration' of the Gallican clergy (1682); and in the various German states it was embodied in the constitutional law: this was no less true of Catholic states than of Protestant.

PLACETAS, plä-sā'täs, Cuba, town, province of Santa Clara, 20 miles southeast of the city of Santa Clara. It is in a fertile sugar district, is connected with Camajuani, and the seaports of Sagua La Grande and Caibarren by rail. Pop. about 6,500.

PLACOIDEI, plā-koi'dē-ī, the name of an obsolete grouping of fishes, including those with placoid scales. See Fish.

PLAGAL, *in music,* the name given by Gregory the Great to the four collateral scales which he added to the four authentic scales of Ambrose. The term plagal is now applied to melodies in which the principal notes lie between the fifth of the key and its octave. The plagal cadence consists of the chord of the subdominant followed by that of the tonic. See Music.

PLAGIAULACIDÆ, plā"jĭ-â-lăs'ĭ-dē, a family of fossil, multituberculate mammals, whose fragmentary remains occur in formations from the Triassic to the Tertiary periods in both Europe and North America. These remains are chiefly of jaws and molar teeth, in many respects foreshadowing those of the marsupials. The typical genus is *Plagiaulax;* others are *Allodin, Bolodon* and *Ctenacodon.* This family, says Woodward, does not seem to have become extinct until early Tertiary times, the genus *Ptilodus* occurring in the Puerco (Eocene) beds of New Mexico. Whether the South African genus *Microlestes,* often associated with these genera, really belongs here is disputed, many palæontologists regarding it as reptilian. Consult Woodward, 'Vertebrate Palæontology' (1898); Beddard, 'Mammalia' (1901).

PLAGIOCLASE, a group of triclinic feldspars (q.v.) in which the two prominent cleavage-directions are oblique to each other. The designation was adopted by Breithaupt. In the group are included anorthite, albite, oligoclase, labradorite.

PLAGIOSTOMI. See Fish; Ichthyology.

PLAGIUM, *in Roman law,* the crime of stealing the slave of another, or of kidnapping a free person in order to make him a slave. According to German law it is the getting forcible possession of a man's person, so as to restrain him of his liberty. By Scotch law the crime of stealing an adult person was punishable with death, and the same punishment has been applied to the stealing of children.

PLAGUE, History of the. The plague, so-called, has been a general name for centuries for any prevailing sickness that carried off great numbers of people. While all the instances recorded below are spoken of as «the plague» it is probable that several diseases have figured in the records. (See Black Death; Bubonic Plague.) Concerning the modes of communication of the plague, very different opinions have been entertained, according to the state of medical science. In early times, when calamitous events, the causes of which were not understood, were attributed to spirits and demons, the plague was also ascribed to their influence. At a later period it was accounted for by changes in the air, by poisonous vapors

which descended from the atmosphere, or was attributed to clouds of insects which were received into the body by inspiration, or in the food, or by absorption through the skin, thus corrupting the blood. There are certain conditions which have always attended outbreaks of the plague. The chief of these are unwholesome and insufficient food, overcrowding, bad ventilation, accumulation in the neighborhood of dwellings of decaying animal and vegetable refuse. In short, these conditions may be summed up in the words, "poverty and bad sanitation." The cold weather of northern latitudes has been observed to check the advance of plagues. In Europe the late summer and autumn months have been marked by its deadliest ravages. It is endemic in certain localities of Asia (parts of Mesopotamia, India, China), and when it has appeared in Europe it seems always to have been traced to the East. It has often been carried by ships, no doubt by one or other of the crew being infected, and not by the merchandise.

There is little doubt that the plague appeared in the most ancient times, particularly where a numerous population was crowded together in the warm climates; but we must not consider every disease as the plague which has been so called by historians, as they often mean by the term nothing more than a malignant disorder prevailing over a considerable extent of country. Among the most famous instances is the plague described in so masterly a manner by Thucydides, which, in the second year of the Peloponnesian War (430 B.C.), ravaged Athens, then besieged by the Spartans. A large number of the inhabitants of Attica had fled into the city. Fear, anxiety, want or poor provision and the corruption of the air caused by the crowded state of the population, produced and propagated the disease in the city. Death generally ensued on the seventh or ninth day. This epidemic does not seem to have been the real Oriental plague, however, any more than that which prevailed in Jerusalem (72 A.D.) when it was besieged by the Romans, as described by Josephus. In Rome the plague existed (77 A.D.) in the reign of Vespasian; of Marcus Aurelius (170), when it raged over almost all Europe and Asia (but this was probably not the real plague); of Commodus (in 189); and particularly of Gallienus (in 262), when 5,000 persons are said to have died daily in Rome. In Constantinople, in the reign of Justinian (in 544), it raged so violently that 1,000 grave-diggers are said to have been insufficient for the interment of the dead. This terrible plague continued its ravages for 50 years with but short intervals. In 565 it appeared under the name of *pestis inguinaria* in Trèves; in 588 in Marseilles. From the descriptions of this visitation given by contemporary writers it was evidently the true Oriental plague, and it had spread over Egypt before reaching Europe. Great mortality from it resulted not only in Constantinople but also in Italy, Gaul and other countries, including northern Africa.

In the 7th century the plague or other serious epidemic raged in Saxony; in 823 it prevailed all over Germany, and from 875 to 877 was particularly malignant in Saxony and Misnia, as was also the case in 964. In the 11th century it broke out in Germany at least six times, mostly after or during a famine, and raged with so much violence that it was believed that all mankind was doomed to be swept away by it. This unfortunate belief prevented the taking of effectual means to check it, and apathy in suffering was considered as an act of piety. In some cases, however, the Jews were suspected of having poisoned the wells, as in a time not very remote the Hungarian peasantry suspected the nobility when the cholera swept away so many of the poorer classes. In the 12th century the plague prevailed in Germany above 25 years. In the 13th century it was brought into Europe by the Crusaders. At the middle of the 14th century it traversed all Europe, and was then called the Black Death. The black death was carried to Europe from the East, having been transmitted, it is said, from Tartary, and ultimately from China, to the Crimea, whence it was carried to Italy by certain Genoese. It also reached Egypt and thence northern Africa. In England it broke out first in the west in 1348, and then spread over the rest of the country, including Ireland and Scotland, its ravages being severest in the towns. After causing an immense number of deaths it reappeared in 1361 and 1369. The black death was the most serious epidemic ever known to have afflicted Europe. In England the proportion of deaths amounted to a third, or even a half, of the whole population. Some towns lost almost all their inhabitants; in Oxford two-thirds of those connected with the educational institutions perished; in London the deaths amounted to 100,000, in Norwich to 60,000. The mortality was naturally greatest among the lower orders; while the clergy and religious orders suffered to an equal or greater extent, no doubt from their efforts on behalf of their suffering brethren. Of those attacked some died almost immediately, others within 12 hours, almost all succumbed within three days. It appears to have been at its height in the summer of 1349. The consequences left behind were great and far-reaching. One was that laborers were so scarce that wages went up to double their former rate, thus leading to the passing of acts intending to regulate them, which had little result except to stir up ill-feeling, ultimately culminating in Wat Tyler's insurrection. Another consequence was the breaking up of many estates into farms let on lease, owing to the scarcity of hired labor by which they could be cultivated under their owners' management. A great accession to the land owned by the Church was another consequence of the black death, which long remained a landmark in English social history. Since that time the plague has never raged with so much violence.

Boccaccio, in the introduction to his 'Decameron,' has given a vivid description of its physical and moral effects in Florence in 1348. In the 15th century it raged in Europe on several occasions, and was accompanied with dreadful sufferings. The historians of that time give terrible pictures of distress. London suffered severely both at the beginning of the century and again in 1428, while a serious outbreak took place in 1472 and subsequent years. In the 16th century the plague again raged, and in 1563 was introduced into England by the return of an English army from the Continent. Though some means were already taken against the

plague — for instance, lazarettos built — yet it raged in Europe on various occasions and in different countries during the 17th century. Holland suffered from it in 1603; in the same year Egypt lost by it about 1,000,000 of its inhabitants. In 1630 Milan was ravaged by it; in 1635–37 Holland again suffered; in 1656 Italy had a dreadful visitation, during which 300,000 persons are said to have died in Naples, 60,000 in Genoa, but only 14,000 in Rome, owing to superior sanitary measures and precautions. On this occasion it spread also to Spain, Germany and Holland. In 1603, 1625, 1636 and 1665 it made great ravages in England. In 1603 there are said to have been 38,000 deaths in London; in 1625, 35,000; in 1636, over 10,000; while 1665 is known as the year of the "great plague" in London, so graphically described, with perhaps some coloring, by Defoe. During the year the deaths are given at nearly one-seventh of the population. The disease spread somewhat widely over the country both in this and the following year. The cessation of the plague in London was attributed to the great fire, and though this no doubt had its local effect, still there was a similar disappearance of the epidemic not long after this time in western Europe.

In 1679 Vienna lost 76,000 of its citizens by this scourge; in 1681 Prague lost 83,000; and various German cities suffered severely. Early in the 18th century the plague caused many deaths in eastern and central Europe, the number in Prussia and Lithuania being set down at 283,000. On this occasion it extended its ravages into northern Europe, Copenhagen and Stockholm having both suffered, the latter to the extent of 40,000 deaths. In Constantinople and other places in the Levant it frequently raged during this century, and in 1720–21 Marseilles and part of southern France were ravaged by the epidemic brought from this quarter. The deaths in Marseilles alone are said to have numbered from 40,000 to 60,000; thousands of corpses lay unburied in the streets. In 1770 it raged in Moldavia, Wallachia, Poland and other adjacent regions, and in 1771 it carried off over 40,000 persons in Moscow, or one-fourth of the whole population. During the 19th century it made itself felt on several occasions in Constantinople and other parts of eastern Europe, in Asia Minor, Syria, Mesopotamia, Arabia, Persia, Egypt and northern Africa, but nowhere did it affect a very wide area. In 1834–35 great mortality was caused in Egypt. It also carried off many thousands in Mesopotamia between 1873 and 1877. In 1878–79 the plague made its appearance on the lower Volga, where it caused a considerable number of deaths.

India has often been visited by this terrible disease, and hundreds of thousands have at various times succumbed to it in that country. In September 1896, several cases were recognized in Bombay, and during the succeeding nine months the disease raged in the city with such severity that the majority of the inhabitants fled to neighboring towns and villages. Poona and Karachi were attacked by the end of 1896, and the disease also spread to more distant parts. A special commission of experts was appointed by the Indian government, and vigorous measures, such as house-to-house visitation, thorough disinfection, and enforced isolation, were adopted. The native municipality of Bombay was for plague purposes superseded by a plague committee. In February 1897, an international sanitary conference regarding the plague sat at Vienna, and after discussion came to the conclusion that the disease was caused by a bacillus discovered in 1894 by Kitasato and Yersin. They also gave countenance to the view that rats, mice and certain other animals, which were liable to attack, probably contributed largely to spread the disease. Bombay was again visited by a serious epidemic in the autumn of 1897, which reached a climax in February of the following year, when the deaths from plague numbered 250 per day. This outbreak also spread to other parts of India, especially in the Bombay presidency, but it was virtually over by June. The sanitary measures of the authorities came into collision with native beliefs and prejudices at various points, and on 9 May 1898 serious riots broke out in Bombay and elsewhere. This led the government to abandon all the more stringent and severe of their preventive measures, and the fact that no harm resulted from their action seemed to justify the statement that the disease takes its own course whatever may be done. Calcutta was first visited by the plague on 16 April 1898, and soon a considerable number of cases were recorded. Bangalore and some other places in southern India suffered severely, and in August, Bombay was again seriously affected. This renewed outbreak passed off in due course only to be succeeded by another, extending from February to July 1899. In 1899 Calcutta was revisited, and other parts of India still continued to lose many lives by this scourge. The plague reached Madagascar in November 1899, and this is the first authentic record of its appearance south of the equator. It was soon afterward reported from Réunion, Mauritius, German and Portuguese East Africa, and West Africa. In July of that year some Spanish sailors arriving at Oporto died of the plague, and it also carried off others in this part of Portugal. The first instance of the plague in the New World was recorded from Brazil in November 1899. Early in 1900 the first case of it was recorded in Australia, but by September that country was practically free from the disease. It has since visited South Africa, and in 1900 there were a few cases at Glasgow. The spread of the plague in India during recent years is shown by the following official figures: In 1897 there were 56,000 recorded deaths; in 1900, 93,000; in 1901, 274,000; in 1902, 577,000. During the single month of March 1903 no less than 136,000 in that country perished from this disease. No city with modern sanitation has suffered from the plague in the 20th century.

PLAGUES OF EGYPT, a succession of inflictions, usually regarded as having been 10 in number, which, according to the Old Testament, were divinely sent upon the Egyptians to compel them to emancipate the Israelites from bondage and allow them to quit the land of Egypt. (Ex. vii. 14, xii. 30. For the use of the word plague, see ix. 14, xi. 1). The first plague consisted in the turning of the waters of Egypt into blood; the second, of frogs that covered the land; the third, of lice annoying both man and beast; the fourth, of grievous

swarms of flies; the fifth, of murrain that attacked the livestock; the sixth, of boils "breaking forth with blains upon man and upon beast"; the seventh, a severe thunderstorm accompanied by destructive hail; the eighth, a plague of locusts that ate what the hail had spared; the ninth, a darkness that could be felt; the tenth, the death of the firstborn of man and beast among the Egyptians. Consult Driver, S. R., 'Commentary on Exodus' (1911); Selbst, 'Handbuch zur Biblisch Geschichte' (Freiburg 1910).

PLAICE, a European flatfish (*Pleuronectes platessa*), allied to the turbot, and highly esteemed as food. It attains an average length of 12 or 18 inches. The dark or upper side is colored brown, spotted with red or orange. They are caught chiefly by means of trawl-nets.

PLAIDS. *A plaid* is a pattern in textile fabrics consisting of bars, or stripes, of color crossing each other at right angles. A *plaid* is a development of the check, which in textile fabrics is a pattern of squares of alternate colors. Properly speaking, a check should have no divisions between the squares more than a thin boundary line. In other words, the pattern should resemble the ordinary chess-board. The word check is derived from an old European custom of settling accounts and computing money by means of counters, or tallies, on a table covered with a checkered cloth. The word comes from the French *échiquier* meaning chess-board.

The *check,* a very ancient pattern, was extraordinarily popular in ancient Egypt as a motive of decoration; and this motive was undoubtedly derived from the woven fabrics and the baskets of plaited reeds and rushes. In the decorations of temples, tombs and houses the Egyptians frequently used a single checker of two colors, dark and light, alternately arranged. Sometimes the form was rectilinear instead of square. Sometimes each square was ornamented by a cross; and in this case the blocks were frequently yellow and green, alternately, and the device (cross) upon them red and black. Occasionally, too, the squares were of various colors arranged in such a way as to form geometrical patterns. Sometimes the squares were cut into halves and the little triangular blocks were grouped so as to make a pleasing effect of form and color. Fabrics, both of linen and wool, exhibited a great variety of motives formed of straight lines — lines horizontal, perpendicular and diagonal. The Egyptians may be said to have "worked the *check* to death."

The *check* is found in nearly every country, ancient and modern, savage and civilized, as a motive of decoration and as forming a pattern for textiles. Scotland is, however, of all countries the home of the *plaid,* there called *tartan,* and affectionately "plaidie" in song, story and legend. The word tartan is derived from the Gaelic *tarstin,* or *tarsuin,* meaning across, athwart, over or through, which, of course, applies to the crossing of the threads in the weaving of any sort of cloth. The word tartan seems to have been applied in early times to the *material* and not to the *pattern.*

To-day the word tartan includes both material and pattern. The French had the word *tiretaine* in the 13th century for "cloth dyed of a scarlet color." In a wardrobe account of James III of Scotland (1471) there is mention of an ell and a half of blue tartan to line his gown of cloth of gold. James V of Scotland in 1538 on a hunting excursion into the Highlands wore a suit made of varicolored tartan.

The variegated pattern has also a Gaelic name — "Cathdath," "war-color," or "the strife of colors." Another name is *plodden.* An Englishman visiting Edinburgh in 1598 wrote, "The citizens, wives and women of the country did wear cloaks made of a coarse cloth of two or three colors in chequer-work, vulgarly called *plodden.*" In 1616 Taylor in his "Penniless Pilgrimage" describes the dress of the Highlanders as "warm stuff of divers colors which they call tartan."

The use of the tartan seems to be beyond the reach of history. The Scotch Highlanders are a remnant of the great Celtic race and were the last to oppose the conquering arms of Rome. When Agricola invaded North Britain in 81 A.D. he found 21 aboriginal tribes, or clans. Clanship, like the tartan which distinguishes its wearers, eludes the historian and disappears in the mists of tradition. The picturesque dress of the

"Bonneted chieftains all plaided and plumed in their tartan array"

is, therefore, one of the most ancient of all costumes.

The clothing of the early Britons was much the same as that of the Gauls. From the Belgic Gauls who settled in Britain, the Britons learned to dress skins, to spin and to weave. The Gauls made several kinds of cloth which they dyed various colors. For the tunic and trousers they used a cloth of mixed colors, forming a check, the prototype of the Scotch plaid. The mantle was generally one color, preferably blue. The Britons were particularly skilful in dyeing; and they used the juice of such plants as the foxglove, sorrel and the famous woad, from which the blue dye was obtained. Color was an important element in British dress. The colors the bards wore were blue, green and white. The Irish Druids wore several colors: the higher the rank, the greater the variety. In Ireland outside the priesthood, color was much esteemed; and the first regulations resembling sumptuary laws in the British Isles were passed long before the Christian Era, ordering the Irish peasantry and soldiers to have their garments of one color only, officers of two colors, commanders of clans, three; and so on. The Royal Family were allowed seven colors. Irish bards wore plaid, or checkered, cloth for their undergarment — a kind of tunic — and over this they threw a long cloak striped in various colors. There is a striking kinship between the Scotch tartan and the checks worn by the Irish in ancient times. In common with the Gauls and ancient Britons the Celts were fond of brilliant colors; and even as far back as 390 B.C. Livy and Virgil assert that these strangers appeared "in flaming tartan garb" before the walls of Rome in that year.

The original dress of the Highlander was the Celtic *Feile-breacan* (belted plaid). This was a piece of tartan about two yards broad and four yards long, which was drawn round

the waist in nicely adjusted folds and tightly buckled with a belt. The lower part came down to the knees in much the same manner as the modern kilt, while the upper part was drawn up and adjusted to the left shoulder so that the right arm might be perfectly free. This upper part was the "plaid," which was used as a covering for the shoulders and body in wet weather. When the use of both arms was required, the plaid was fastened across the breast with a brooch, often curiously enriched. A brooch was also used to fasten the plaid on the left shoulder. To attire himself in the *belted plaid* required on the part of the Highlander no small amount of dexterity. The usual way was to lay it on the floor, or ground, and, after carefully arranging the folds, to lie down upon it and then buckle it on. The lower end was fastened at the right hip. This arrangement appears in the illustration of the Earl of Moray engraved in Lord Archibald Campbell's "Records of Argyll."

The utility of such a dress in the Highlands is obvious, for the "plaidie" rendered the man indifferent to storms and prepared to pass a night in the open air in the most inclement weather, while the loose undergarment enabled him to wade rivers, or ascend mountains, with equal ease. The plaid was thus peculiarly adapted to the warrior, hunter and shepherd. If benighted, the Highander of old would dip his plaid in water and then wrap it around himself. The woolen cloth, swollen with moisture, was supposed to resist the wind, while the exhalations from the body during sleep surrounded him with a warm vapor.

In Heron's 'History of Scotland' we read that in Argyll and the Hebridæ before the middle of the 15th century tartan was manufactured of one or two colors for the poor, and more varied for the rich. The author of 'Certain Matters Concerning Scotland,' who wrote prior to 1597, said that the "Highlanders delight in marbled cloths, especially that have long stripes of sundry colors; they love chiefly purple and blue." The particular patterns of tartans which distinguish each clan, must have been fixed before 1645, probably before 1600. Martin noted that the different isles in the west had different patterns of tartans and he also remarked that the women of the Western Isles wore sleeves of scarlet cloth and a plaid tied before on the breast, held with a buckle of silver, or brass, according to the quality of the person. The plaid was white with a few stripes of red, black or blue, reaching from neck to feet and belted with a leather girdle studded with silver. The tartan was worn in this style by ladies in the 18th century and is still so displayed at fancy and costume festivals.

The Highlanders had neither cochineal, foreign woods, nor the many brilliant hues produced to-day; but their native hills yielded wonderful dyes. Every housewife was able to dye red, blue, green, yellow, black and brown with their various compounds. As many of the ancient dyes are still used in the Highlands it is interesting to note from what native flora the dyes were obtained. Black was from alder tree bark, dock root and water fly root; blue, blueberry with alum, or elder with alum; brown, lichen, dulse, currant with alum, blueberry with gall nuts; crimson, white lichen, dark lichen; flesh color, willow bark; grey, root of yellow water-flag; green, broom, whin bark, teasel, heather with alum; magenta, dandelion; orange, bramble; purple, sun dew or cupmoss; red, rock lichen, white lichen, rue root, or tormentil; scarlet, limestone lichen; violet, wild cress; and yellow from bog-myrtle, ash tree root, bracken root, Saint John's wort, teasel, lichen, common heather with alum and sun dew with ammonia.

According to Captain Burt in 'Letters from a gentleman in the North of Scotland to his friend in London,' written in 1730, —: "The chequered stuff commonly worn by the Highlanders, by them called breacan (parti-colored) and by the Lowlanders tartan (French, *tiretaine*), is neither peculiar to Celts nor Goths, and is to be found at this day, although not in such general use, among many of the Slavonic tribes, who have no connection with either." Captain Burt also says that when the Highlanders are trained to lie among the hills in cold, dry, windy weather, they sometimes soak the plaid in some river or burn, and then holding the corner up above their heads, they turn themselves round and round until they are enveloped in the whole mantle and then lay themselves down on the leeward side of some hill where the wet and warmth of their bodies makes a steam like that of a boiling kettle, and keeps them warm by thickening the stuff and keeping the wind from penetrating."

For a long period the "belted plaid" was the dress of the Highlanders. Early in the 18th century it was succeeded by the little kilt called the *feile beg,* or *fillibeg,* and was much the same in appearance as the modern kilt worn to-day. The little kilt was made of six ells of single tartan, plaited, sewn and fixed round the waist with a strap, half a yard being left plain at each end and these crossed each other in front. Kilt is a Lowland word signifying a shortened, or tucked-up-garment. The plaid figured largely in Lowland politics. Allan Ramsay, who was throughly Jacobite, supporting the claim of James Stuart to the throne in 1715, wrote a poem "Tartana, or the Plaid," which specially refers to the wearing of tartan plaids by the ladies, a custom then universal in the Lowlands.

The kilt is worn to-day so that when the wearer is standing erect the edge of it should reach the centre of the kneecap. The kilt is the principal part of the Scottish dress and should be made of tartan associated with the name of the wearer. In absence of any claim to wear a particular tartan, the Royal Stuart tartan can be worn. The shoulder plaid is merely ornamental, but should always be worn with evening dress. The lower end of the plaid is fastened round the waist by a band and the other end is pulled through the epaulette on the left shoulder, where there should be a rosette on the plaid through which a brooch is fixed. This can be of any design provided it is round and may have a Cairngorm, or other stone, in the centre, or it may be made after the pattern of the Lorne brooch.

Stockings used to be made out of the web of tartan but they are now knitted. Tartan ribbons, like stockings, are attached to the garters.

In order to understand the significance of the clans it is well to remember that Scotland

was divided in two parts: the Highlands and the Lowlands. The Highlands comprised the northwest of the country, occupying little over half the area. Formerly the map of Scotland was divided into clans and countries. A clan means a family, or tribe, all loyally under the will of a chief, or chieftain. The Highlands were divided up among 31 clans. Each clan had a dress of distinctive tartan. In some cases a clan had more than one design. The Stuart and Campbell clans and some others had five. In such cases there was a special tartan reserved for the chief. The others wore the dress tartan (in which the plaid appears on a white ground), and the hunting and mourning tartans. Thus while there are but 31 clans in the Highlands there are 96 Highland tartans. Ignorance of this leads to many disputes as to the correctness of a particular tartan, it being generally thought that a clan had but one tartan.

It should be remembered that a "clan tartan" is the specific variety of tartan worn by a Highland clan and to be worn by all members of one family — Campbells, Camerons, Grants, etc. There are certain refinements of distinction; for instance, separate stripes are used to distinguish a chief or two divisions of the same house. Tartan as a distinguishing clan mark seems to be a survival of totemism. It was so arranged that a man could tell to what district as well as to what clan the wearer belonged. There are also two tartans which do not belong to any family; one distinguishes an order, the clergy; and the other, a cause, the Jacobite, or Stuart.

Of the total tartans about one-half are of red ground and one-half are black, blue and green. The Rob Roy is the easiest of all to recognize, as it is a simple red and black check. The Black Watch, or Forty-Second, is black, blue and green. It is often mistaken for the Sutherland, similar in design but lighter in color. The MacMillan is easy to recognize for it is pink, yellow and white; and the very striking and handsome Menzies (pronounced Mingies) is scarlet and white. There are only four tartans with two colors only. The greater number have five colors. Those with black, blue and green ground have stripes, white and red, or yellow and red, or yellow and white. When there are four colors the stripe is white or yellow and red. There are never more than six colors in any tartan, although some of them at first sight appear to have many more. An example is the Ogilvie.

There are three shades of blue and green, but only one shade is used in the same plaid with the exception of the clergy tartan, which has two blues: one is dark and one is light, representing things below and things above. The hunting MacPherson is alone in having gray. Neither violet, nor brown, is employed in tartans, but when blue and red are intermixed in the weaving, they produce a brown effect which is particularly marked in the Erskine, which has but these two colors in equality. The Elliot is the bluest and the MacArthur the greenest of all the tartans.

In Scotland all the big dry-goods houses keep a stock of tartans of all clans, but outside of Scotland they are hard to find. Some London houses keep a complete "set." The word "set" refers to the size of the design of the tartan and signifies the number of spaces between the colored lines to the width of the tartan from 4 to 24. Thus, a "4-set plaid" has 4; a "16-set," 16; and a "24-set," 24. All tartans are made in piece goods and traveling rugs as well as the typically Scotch body wrap, or shawl or "maud," as it is locally called; it is correctly three and one-half yards long and is used throughout Scotland for mountaineering.

All regular tartans are made so that in the folds of the kilt and plaid, which are made into quilted or box-plaiting, a particular stripe shall appear. Thus, in the Gordon set the stripe is yellow; in the MacKenzie, white; and so on. The plaid over the shoulders is also adjusted carefully so as to exhibit the distinguishing stripe of the family.

One of the most famous tartans is that of the "Black Watch." This has no clan significance. It is entirely military. When General Wade in 1725 was sent to Scotland to pacify the Highlands, in pursuance of the act for disarming the Highlanders, he gave orders that the six companies in existence should adopt a uniform tartan; and this being of a dark color gave rise to the name of the Black Watch. In 1739 these six companies were formed into a regiment and the history of the Black Watch began. Ever since Fontenoy this regiment has been associated with some of the greatest deeds accomplished by the British army. The great fame of the Black Watch caused other Highland regiments to be formed: the 71st and 72d in 1773; the 74th in 1788; the 78th in 1793; the 79th or Cameron Highlanders in 1795; the 92d or Gordon Highlanders in 1796; and the 93d or Sutherland Highlanders in 1800. The dress of these regiments has become a national feature and has done more than anything else to perpetuate the wearing of the kilt. The Battle of Culloden (1746), where Prince Charles, Edward Stuart, grandson of James II, was defeated by the Duke of Cumberland, ended the clan system.

In that year (1746), the wearing of the tartan was prohibited by the British Parliament under penalty of six months' imprisonment. This act was repealed in 1782, through the efforts of the gallant Duke of Montrose.

In the 36 intervening years the weaving of the Highlanders ceased in the Highlands and many of the old "sets" or patterns were forgotten. Owing to the fact that the tartan was worn in the Lowlands, particularly in Edinburgh, where the ladies made it a fashionable craze, it was possible to revive the ancient fabrics. From 1782 onward the wearing of the tartan became general throughout Scotland, and the romances of Sir Walter Scott, who peopled the country with fascinating heroes and heroines, gave a new and poetic interest to the national dress.

During the World War the Germans called the Highland regiments "Ladies from Hell."

The king of England and all branches of the royal family wear the royal plaid of the high steward of Scotland, whose name is, in consequence of the office, Stewart (or Stuart). The Prince of Wales, as Lord of the Isles, wears the red and green plaid with intersecting black lines of that district. The Duke of Sussex, who is Earl of Inverness, wears the

Inverness. In modern times many tartans have been invented, manufactured and named after the Border tribes of the Lowlands, such as Douglas, Johnston, Lindsay, etc., and many fancy tartans in various sorts of fabrics have been manufactured, particularly for women's dresses. Silk tartan and tartan velvet (with short nap woven in plaids) have been manufactured for women's dresses and men's waistcoats, and at certain periods have been extremely costly and fashionable. Every sort of article appears in Scotland in the national tartans: capes, skirts, boys' suits, kilts for little boys and girls, underpetticoats, ties, tam o'shanters, blouses, shawls, rugs, kummerbunds and linings for bags and satchels.

The Lowland "Shepherd's Plaid," or tartan, is a woolen cloth made into small checks of black and white. This is also called a "maud."

The check and plaid appear in many varieties in the cotton, woolen and silk goods made in India. Agra, for instance, turns out large quantities of checked and striped cotton cloths. Gingham comes from a Malay word, meaning striped. It is of cotton, or linen, woven of dyed threads in stripes or checks and plaids. Ginghams were much worn in the 18th century. For example, the *British Magazine* (1763) notes that "Ladies of taste are prodigiously fond of the ginghams manufactured in Manchester." *Khes* is the name by which a stout fabric, woven in colored check patterns, is known in the Punjab. The loom for khes weaving is wider than usual and the cloth is prized for winter wraps. Dark red, dark blue and white are the usual colors. These cloths are something like the ginghams and checks of England. They are mostly woven with yarn brought from England, or are Bombay mill-spun. Another kind of check cloth, largely made at Ludhiáná, is called Gabrun or Gamrun. It is still better known as Ludhiáná cloth and is much used by Europeans for summer clothing.

In Multan and Bháwalpur, where variegated silks are produced, checks are among the favorite patterns. In Pesháwar, Kohát, Sháhpur and Bháwalpur silk *Lungis* are made. These are woven of various colors and often with gold thread interwoven for extra beauty. *Lungis* are chiefly worn for turbans and are extensively used on the Punjab frontier, as they are considered handsomer than white turbans. Some of the arrangements of stripes are, like the Scottish tartans, distinctive of certain *Khels*, or clans.

Khes, described above as made of cotton, are also made of silk, sometimes plain, sometimes in patterns. "The *Khes*," writes Baden-Powell, "is also woven in silk, either check pattern in squares, or plain silk with a gold border and edged with some fancy pattern."

Blankets of goat's hair are produced in the hill districts of the Punjab. These are often woven into a check pattern. Various kinds of silk and cotton mixed fabrics are made in the Maldah district: Sabzikatár, for example, is of a green ground with fine stripes of checkered crimson and yellow, with figures resembling a dagger between the stripes.

Bulbulchasm has a gold ground with diamond patterns, compared to the eye of the nightingale (bulbul). In many provinces silk and cotton weaving with warps and wefts, which have been separately tied and dyed by the Bandháná knot-tying process, is practised. From this name is derived the *bandanna* handkerchief, which the old Southern negress used to wear in the form of a picturesque turban.

Thus the migration of the check in all its various manifestations and varieties brings mankind together strangely; and the old distinction of plaid and checks, which was used originally to label clans and families, lives to-dav as a popular and useful motive of decoration.

PLAIN (Lat. *planum*, level ground), a tract of land which is level or undulating. That portion of the earth's surface not covered by water may be classified into two great divisions, namely, mountains and plains. This broad classification includes under plains all broad tracts whose surfaces are not so elevated as to be included among mountains. The plains may be classified as the narrow tracts of land, with high land or mountains bordering the sides, as valleys; the broad expanse of level or rolling land of an altitude of 1,000 feet or over, as a plateau, and all the broad plain-lands below 1,000 feet are classified as plains. This classification is not always followed, as many of the plateaus of the world are called great plains. Another method of classification is by the nature of the formation of the plain. The rivers of the world which enter the ocean deposit each year a large amount of débris brought down from the mountains. The ocean currents and tides distribute this deposit over the ocean bed and, in some places, a constant process of plain-building is in progress. As the amount of soil accumulates, the plain grows higher until it becomes a part of the continental land mass. Such tracts of land are called marine plains. The North Atlantic marine plains formed on both the east and west coasts are now so broad that the coast plain on both sides extends far out, below the surface of the water. The fossils found in the strata indicate the origin of the Atlantic Coastal Plain. Tracts of land that were once the beds of great lakes, but which have dried up, are called lacustrine plains. Lacustrine plains exist around Great Salt Lake in Utah, and in Nevada, the valley of the Red River of the North, the vale of Kashmir in northwestern India, and the great Hungarian Plain. The deposit of silt at the mouths of rivers, and sometimes along the banks make fluviatile plains, or flood-plains. The Mississippi, Po, Ganges, Nile and other large rivers have constructed great fluviatile

plains, and the mighty builders still continue their work. Still another origin for plains is erosion, by means of which the mountains are lowered and the broad tract of rolling or hilly land forms. Such formations are called plains of denudation. Where considerable of the former mountain area remains, the lowland formed by erosion or denudation is called a peneplain. In respect of fertility plains show all gradations from wholly barren salt plains, such as the salinas of Argentina, in South America, and almost wholly barren deserts, such as are represented chiefly in Africa and Asia, to the highly productive alluvial plains of such great rivers as the Mississippi and the Ganges. Various special kinds of plains in different parts of the world are distinguished by special local names. Among these are the landes, or sandy plains in the southwest of France; the treeless steppes of southern Russia in Europe and Central Asia; the marshy tundras of northern Siberia; the arid karroos of Cape Colony; the savannahs and prairies of North America; the grassy llanos of the Orinoco Valley; the forest plains or selvas of the Amazon basin; and the treeless and partly barren pampas of Argentina. The great desert plain of the world is the Sahara (q.v.) in Africa, extending from the west coast of Africa to the Red Sea, a distance of over 2,500 miles; and over 1,000 miles wide from north to south. This desert plain is made of bare ledges of rock miles in extent, oceans of sand, white in some places on account of the salt. Beyond the Red Sea the desert lands extend, including the Arabian plain, and plains in the interior of Asia, into China almost to the Pacific Ocean. It must not be understood, however, that all deserts are plains; many are highly mountainous. The great plains of the interior of Africa, south of Sahara, are covered with dense vegetation. The interior of Australia, so far as known, consists of extensive low plains upon which the waters of the rivers become stagnant amid gigantic reeds and herbaceous brushwood. The long dry seasons to which the country is subject make the plains vast deserts. The falling of the rains, however, speedily converts these dusty wastes into verdant pastures. Central Asia is a region of immense mountain chains supporting tablelands of great extent. The northern parts of the same continent and of Europe present in a range of more than 6,000 miles a succession of broad plains, covering the greater part of Siberia, a large part of Russia, Germany and Holland. On this range, from the Pacific to the Atlantic, are no elevations exceeding a few hundred feet. These plains in Siberia and Russia are called steppes, and large portions of them are rich pasture lands, without trees, and much resembling the prairies of the Mississippi Valley. The American continent, north and south, is eminently a land of plains. They form full two-thirds of the whole surface of the country, extending on the Atlantic side from one extremity of the continent to the other, with only occasional interruptions by mountain ranges of little extent. In South America are distinguished three great regions of plains separated from each other by low ranges of mountains, which run from the Atlantic Coast toward the Andes. The northern of these regions, having an area of 260,000 square miles, comprises the valley of the Orinoco and its tributaries, and the elevation of this great territory nowhere exceeds 300 feet above the sea-level. So smooth is the surface that over hundreds of square miles the land is almost as unbroken by any unevenness as the water itself, and the rivers are so sluggish that their current is diverted in any direction by light winds. This is the region of the llanos (Lat. *loca plana*). In the dry season the ground is parched and barren, and clouds of fine dust and sand incessantly rising fill the air. The grasses, which in the rainy season suddenly spring up and grow to the height of four feet, are withered and crumble into dust. But as the vegetation appears with the return of the rains, the plains are soon overrun by vast herds of horses and wild cattle, which then find a rich pasturage; and from the jungles of the river banks, to which they had retired during the drought, the great serpents and alligators make their appearance and overspread the plains. The only interruptions to the dead level of the surface, beside the depressions of the beds of the rivers and creeks, appear to be occasional banks of limestone or sandstone, called bancos, standing four or five feet above the general surface, flat at the top, and several leagues in length. Slight undulations, called mesas, imperceptible to the eye, are indicated by the water-courses which are turned by them in different directions. The plains of the Amazon extend up the course of that river and its branches to the Andes, and include, with all the waters they enclose and some ranges of hills, an area of 2,340,000 square miles. About one-third of this territory is covered with dense forests, the principal portions of which have not been explored. So luxuriant is the vegetation and enervating the climate, that to reclaim any considerable extent of these wilds is a task almost beyond the ability of man. From their wooded character the plains here are called selvas; but open tracts like the llanos are scattered among the forests, and numerous broad rivers occupy large areas and afford the only means of gaining access to the distant interior. The plains of the southern portion of South America, lying beyond lat. 15° S., are termed pampas, from an Indian word signifying a flat. They resemble the steppes of Russia, being open grass-covered tracts of vast extent, interspersed with barren areas composed of rocks and sand. Their total extent from north to south is about 1,800 miles, and from east to west from 300 to 900 miles. On the north they reach the region of tropical productions, and at the extreme south their surface is in many places concealed beneath the never-melting ice and snow of those frozen latitudes. Across their range from the coast to the Andes three belts are recognized in their northern division, distinguished from each other by their peculiar productions. The first is strongly marked by its singular growth of tall thistles succeeded by clover. The former come forth with wonderful rapidity in the early summer, shooting up to the height of 10 or 11 feet, and bearing a profusion of rich blossoms. So close are the stems, that even if unarmed with their prickles they would still present an impenetrable barrier. As the summer passes away this vegetation dies down, and luxuriant crops of clover spring up, and invite the return of the countless herds of cattle

which were expelled by the thistles. To the west of this is a belt of plains covered with long grass, which from season to season undergoes little change except as the green of summer changes to the brown hue of winter, and this gives place to the verdure of the succeeding spring. Beyond this is a region of more elevated plains lying along the range of the Andes, and covered with low trees and shrubs, all evergreens. The plains of North America, while no less extensive than those of the southern part of the continent, are distinguished from them by greater diversities of level, which, together with the climate, render the country better adapted to the necessities of man. Excepting the parts covered by the Rocky and Alleghany Mountains and their spurs, all the rest are plains uninterrupted by mountain elevations. Near the mountains the surface is hilly and more or less broken, but receding from the Alleghanies westward it gradually assumes the distinctive character of plains, which are developed upon a grand scale in the boundless prairies of the northwest, and in the barren territories commonly known by the name of plains which stretch away from the prairie region in the States of Arkansas, Missouri and Kansas to the foot of the Rocky Mountains. Throughout these immense territories the differences of level are sufficient to produce a steady flow in the mighty rivers, not so rapid as to obstruct their navigation, but sufficient to insure salubrity to the country by a healthy drainage; and thus is secured a system of easy intercommunication between all sections of the country, unsurpassed in importance by any similar system in the world. In the first volume of the geological report of Iowa Prof. James Hall has presented a full account of the northwestern prairies. The region they occupy is the western part of Ohio, nearly the whole of the States of Indiana, Illinois and Iowa, the southern part of Michigan, the northern part of Missouri and portions of Kansas and Nebraska, in which, near the meridians of 97° and 100° W., they gradually pass into the arid and desert plains. Throughout this territory a great sameness exists in the varieties of the topography, the vegetable productions, the soil, and geological features. The surface is drained by streams which commence in almost imperceptible depressions of the high prairies, and flow in beds and valleys of gradually increasing depth between vertical walls of limestone or sandstone, through the horizontal strata of which the current has in past times made its channel. What are called bottom lands lie between the rocky bluffs and the stream, and upon the Mississippi and the Missouri, these attain in places a width of six to eight miles; they are, however, often wanting entirely, the bluffs on each side coming close to the river banks. On the upper Mississippi the bottom lands are in general well wooded, but along the State of Missouri they spread out into open prairies. These low or wet prairies are distinguished from the high or rolling prairies, which form the general upper level of the country upon the summit of the bluffs. The elevation of these above the rivers is very variable. Near Prairie du Chien in Wisconsin, it is about 400 feet above the Mississippi, and the bluffs themselves present a vertical face of about 300 feet. At Cairo in Illinois, the upper surface is from 100 to 250 feet above the river, or 400 to 550 feet above the sea-level. In the central portion of the State, near the Illinois Central Railroad, the average elevation is from 650 to 750 feet above the sea, and near the northern border of the State this increases to 800 or 900 feet, and some of the highest swells of the prairie are 1,000 feet high. In southern Wisconsin the more elevated portions of the prairie are about 1,100 feet above tide water. In Iowa the *plateau du coteau des prairies* of Nicollet, dividing the waters of the Mississippi from those of the Missouri, is from 1,400 to 1,500 feet above the sea. On the head waters of the Illinois and Wabash, and south and west of Lake Michigan, the prairies are very level and smooth, and are termed flat. Elsewhere the surface is undulating and broken by the depressions of the streams, and they are known as rolling prairies. The depressions where there are no streams are often 50 feet below the mean level, and in the bottom the soil is wet and marshy and forms "swales" or "sloughs," which render the roads almost impassable. In these places the grass grows very rank and tall, but upon the upper and drier surface the natural growth is finer and the sod dense and closely interwoven. A great variety of flowering plants are interspersed among the grasses, and during the summer the whole surface of the prairies is gaily decked with bright colors. The characteristic herbs, as described by Professor Gray in a paper on the "Flora of the Northern States," published in the 'American Journal of Science' (2), xxiii, p. 397 (1857), would seem to be compositæ, especially helianthoid compositæ, of many species. Trees are in scattered groups, or along the larger streams, or occasionally on low rocky ridges. West of the Mississippi they become less frequent, and near long. 98° W. they disappear altogether. The soil of the prairies is remarkable for its finely comminuted condition. It is generally free from stones, though in some localities boulders or fragments of rock are found upon the surface and scattered through it. In the swales and in some of the bottom lands the rich black vegetable mold is very deep, but on the upper prairies its depth is usually from one to two feet. The subsoil is almost invariably an argillaceous loam, more or less mixed in its lower portions with sand and occasional pebbles. The total thickness of clay, sand and loam amounts in some places near the larger rivers to 200 feet, but the rock is often found in other places very near the surface. Water is generally found in the sandy stratum 15 to 30 feet below the surface. Throughout the prairie region the underlying rocks are soft sedimentary strata, especially shales and impure limestones. Most of these on exposure disintegrate readily and crumble to soil, and the whole soil of the prairies appears to have been produced from such materials not removed far from their first beds. To the finely comminuted condition of these materials Professor Hall ascribes the treeless character of the prairies. Where such soils are found in portions of the western part of North America, covering tracts of limited area, even enclosed in thickly wooded districts, they are commonly without trees; and as is the case with the vast treeless plains of the Mississippi

Valley, no ancient trunks buried in the soil indicate that the localities were ever covered with trees.

PLAIN, Fort, or **FORT McKEAN,** a former fort of Revolutionary days, located at the junction of the Mohawk and Osquaga creeks, in New York State.

PLAIN SONG (Plain Chant, *Cantus planus,* Gregorian Chant), the most ancient and simple form of church music, consisting of easy progressions in one of the church modes, suitable for use by priests or a congregation. When counterpoint was introduced, it was customary to compose parts above or below a portion of ancient plain song; hence the term plain song is often synonymous with *canto fermo,* or the fixed melody to which counterpoint is added. It differs from modern music, (1) in its recitativo-like character, as opposed to barred music; it has no marked and regular rhythm; the rhythm of a piece of modern music is indicated by the signature as being either in common or in triple time or some variety of these, and the stave is divided into bars or passages equivalent in length; but in plain song there is no such division, and the rhythm of the music is derived from the metrical rhythm of the psalm or hymn rather than vice versa. (2) The *modes* or scales in which plain song is written are more numerous and varied than the modern major and minor. (3) The notation of plain song is by means of a stave of four lines, on any one of which either of the two received clefs (C and F) may be set and so determine the sound of all other notes, above and below. Originally the notes in plain song were all of one length; they are now of three kinds, longs, breves and semibreves, the long being equal to the breve and semibreve. The *modes* of plain song are named after the ancient Greek modes — Dorian, Phrygian, Lydian, etc., but beyond the name there is no relation between the two systems. The principle of the plain song modes is that each of the seven natural sounds of the diatonic scale forms the key-note or "final" of a mode, which comprises that note and the seven above it. (The melodies rarely exceeded an octave, and no flats or sharps are used except an occasional B flat). This gives seven modes; but to each of these is attached another, in which the melody, while having the same "final" or key-note, instead of rising to the octave above, ranges from the fourth below it to the fifth above; these are the *authentic* and the *plagal* modes respectively. The difference between an authentic and a plagal melody may be illustrated from the two psalm tunes *Newton* or *New London* and the *Old Hundredth;* in the first the melody lies between the key-note and its octave, but in the other between the fourth below and the fifth above the key-note. Of these 14 modes two are universally rejected in practice as defective — the 11th and 12th. In the following table the notes of the scale are indicated by the letters of the alphabet according to modern notation; the "final" or key-note in each mode is distinguished by full-face type.

Authentic Modes	Plagal Modes
1. Dorian, **D** E, F, G, A, B, C, D.	2. Hypodorian, A, B, C, **D**, E, F, G, A.
3. Phrygian, **E** F, G, A, B, C, D, E.	4. Hypophrygian, B, C, D, **E**, F, G, A, B.
5. Lydian, **F** G, A, B, C, D, E, F.	6. Hypolydian, C, D, E, **F**, G, A, B, C.
7. Myxolydian, **G** A, B, C, D, E, F, G.	8. Hypomyxolydian, D, E, F, **G** A, B, C, D.
9. Æolian, **A** B, C, D, E, F, G, A.	10. Hypoæolian, E, F, G, **A**, B, C, D, E.
11. Locrian, **B** C, D, E, F, G, A, B.	12. Hypolocrian, F, G, A, **B**, C, D, E, F.
13. Ionian, **C** D, E, F, G, A, B, C.	14. Hypoionian, G, A, B, **C**, D, E, F, G.

The Ionian is the modern major mode. In one or other of the 12 approved modes every plain song melody is composed. The psalm tunes are written in the eight modes one, three, five and seven (authentic), and two, four, six and eight (plagal); the 114th psalm, *In Exitu Israel,* has from ancient times been sung to a peculiarly beautiful melody in mode nine, the *Tonus peregrinus:* ancient tradition traces this tune back to the time of the Maccabees and the purification of the Temple after the first victories of Judas Maccabæus (165 B.C.) on which occasion were sung the psalms of the Hallel (Ps. cxiii-cxviii); and it is highly probable that all the psalm tones used by the church had their origin in the Jewish Temple-service. From the beginning vocal music was employed in the church service and formed an important part of it. At first the tones and melodies were handed down orally, afterward some crude system of notation was devised, but it was defective, and was reformed by Saint Ambrose, bishop of Milan (4th century), who brought to the West the mode of chanting which he had learned during his residence at Antioch: the 'Ambrosian chant' was founded on the first four authentic modes, and was sung antiphonally. Till the pontificate of Gregory I it was widely in use in the Western churches; but after Gregory's reform the Ambrosian chant was disused, and is now practised only in the cathedral and diocese of Milan. How Gregory noted the music is uncertain; the early notation and rules of plain song were so complicated that it is said 10 years' study was necessary to acquire mastery of them. Among the plain song melodies used in the Roman church service of the Holy Week, those of the Lamentations of Jeremiah and of the *Exultet,* a portion of the Holy Saturday service, are by musicians declared to be "beautiful beyond all description"; and the *Exultet* has been regarded as the finest example of plain song in existence.

PLAIN TALES FROM THE HILLS, Rudyard Kipling's first book, originally published in Calcutta in 1888, quickly drew the attention of European and American critics to "this cocksure young man from India" who was opening our eyes to a new world. These stories, with their breezy, individual style and unusual plots, portraying Anglo-Indians in social, official and military life and giving a few glimpses of mysterious native ways, soon established the young Anglo-Indian journalist in the minds of Western readers as the literary discoverer of modern Hindustan. As Andrew Lang wrote of the author, "For the first time he has shown English readers what India is like; how full of infinitely various life and romance." Many of the tales, as less favorable critics have remarked, are somewhat marred by

youthful cynicism and a method that is rather too journalistic; and it has been objected that they unfairly emphasize the less pleasing features of Anglo-Indian society; yet their interest is unfailing, and they are full of the promise so amply fulfilled in the author's maturer work. In the later authorized editions, the collection consists of 38 stories, among them 'Lispeth,' the story of a Himalayan Hill-girl: 'Three and an Extra,' introducing Kipling's social heroine, Mrs. Hauksbee; 'Miss Youghal's Sais,' being the romance of the author's favorite secret service officer, the redoubtable Strickland; 'Thrown Away,' the pathetic story of a young subaltern, and such vignettes of native life as 'In the House of Suddhoo,' 'Beyond the Pale,' 'The Gate of a Hundred Sorrows' and that tender little tale of a brown baby, 'The Story of Muhammad Din.'

ARTHUR GUITERMAN.

PLAINFIELD, Conn., town in Windham County; alt. 220 feet; 29m. NE. of New London; on the New York, New Haven and Hartford Railroad. It is on the Moosup River, a tributary of the Thames; and Moosup is the largest village in the town. Up to the late 1930's the town was busily engaged in large-scale manufacture of textiles. There are public libraries in some of the villages within the town. In Plainfield village the Plainfield Academy was founded in 1778. Another village in the town of Plainfield is Wauregan; it is a mill settlement on the Quinebaug River. The town was first settled in 1690, and was originally called Quinebaug. It was incorporated as a town in 1699. Pop. (1930) 8,027; (1940) 7,613.

PLAINFIELD, N. J., city in Union County, alt. 100 feet, on Green Brook; on the Central of New Jersey; Philadelphia and Reading; and Baltimore and Ohio railroads; about 15 miles west by south of Newark and 24 miles west of New York City. It is on a level plain at the base of the first Watchung Mountain, the ridge or uplift in the northeastern part of the state. Plainfield is the trade center for a considerable area, including North Plainfield, South Plainfield and Netherwood. Long a residential city, it now has a wide variety of manufactured products: printing presses; concrete machinery; motor trucks and engines; electric motors; radio condensers; chemicals; tank cars; gas meters; stockings; underwear; hats; tents and awnings; lumber; tools and hardware supplies. Quaker and Scotch Presbyterian settlements here began about 1685. A grist mill on Green Brook, gave the place the name of Milltown. Plainfield became the official name in 1800. The township was incorporated in 1847. In 1869 it was chartered as a city. There is an old Quaker meeting house here. Washington's Rock is a State Park. It has a mayor and council. Pop. (1940) 37,469.

PLAINS OF ABRAHAM, An elevated tableland above Quebec, on the west and southwest boundaries of the city. It was named after Abraham Martin, one of the pioneers of French Canada. It formed the scene of the famous battle between French and English which determined the mastery of the New World, when the British forces, under James Wolfe (q.v.), defeated the French under Montcalm (q.v.). Both leaders were mortally wounded in the engagement; the spot where Wolfe died is marked by a monument and not far distant is another, erected to the joint memory of Montcalm and Wolfe. The ground now commonly known as the Plains of Abraham, which was purchased by the government and given to the city of Quebec in 1908, and called the Park of the Battlefields, formed no part of the scene of the famous conflict, nor was any portion of this ground ever owned by Abraham Martin.

PLAINVIEW, Texas, city and Hale County seat; alt. 3,366 feet; on the Fort Worth and Denver City and the Panhandle and Santa Fe railroads; 75m. S. of Amarillo. Hale is an agricultural county, producing cotton, wheat, and alfalfa; also, poultry, hogs, and cattle. The city has good modern buildings. It is the seat of Wayland Baptist College. Government is by mayor and council; the water supply system is city-owned. Pop. (1930) 8,834; (1940) 8,263.

PLAINVILLE, Conn., town in Hartford County; alt. 170 feet; 14m. SW. of Hartford; on the New York, New Haven and Hartford Railroad. Its products are electrical supplies and steel bearings. The public library has a collection of Indian relics. Pop. (1940) 6,935.

PLANARIAN WORMS. The term is usually employed to designate free living flatworms included under the *Turbellaria.* They are distinguished by the presence of a triclad or polyclad alimentary canal. The fresh-water forms (triclads) are abundant in ponds or streams, where they occur on stones, sticks and water plants. The soft body is elongate and moves in a gliding manner by the action of the ciliary coating of the epidermis. Marine planarians (polyclads) are broader, leaf-like and much larger. Land planarians are rare beyond the tropics and sub-tropics, where they occur abundantly in moist regions and are photophobic in habit. In form they are much elongated, cylindrical and of considerable size, while the body is often brilliantly marked by colored bands. The food usually consists of higher worms, mollusks and insects, although a few have become true parasites. Consult Graff, 'Monographie der Turbellarien' (Leipzig 1882–99); Woodward, 'Bulletin Harvard Museum' (XXXI, 1898).

PLANCHETTE, plăn-chĕt' (Fr. plăn-shĕt), a thin heart-shaped piece of wood supported on two castors at the ends of the base and on an ordinary pencil at the apex that was popular about 1860 to 1880, before the Ouija board supplanted it. If the finger-tips be placed upon this device, the pencil may readily be made to trace characters without conscious movement on the part of the operator. Like the Ouija board it was used by two classes of persons: (1) Believers in Spiritualism, who asked questions of a spiritual control and believed that they received answers from intelligences on the spirit plane; and (2) people who regarded the mechanism as a game and amused themselves by pushing it to write messages for the benefit of others present. When used by some persons the planchette seemed to begin to move of its own accord after a little space of time and if the person wished, for instance, to have an answer to a certain question, writing was formed on the sheet of paper on which the instrument was placed, containing something

more or less pertinent to the matter. Consult Huntley, F., 'The Great Psychological Crime' (Chicago 1912).

PLANÇON, pläń-sôń, **Pol,** French bass singer: b. in the Ardennes, France, about 1855; d. 1914. He studied music at the Ecole Duprez in Paris and in 1881 made his début at Lyons in 'Les Huguenots.' In 1883 he appeared in the Paris Grand Opéra as Mephisto in 'Faust' and scored a great success, which was followed by an equally praiseworthy presentation of Ramfis in 'Aïda.' He was warmly received at the Metropolitan Opera House in New York. He created rôles in Saint-Saëns' 'Ascanion'; Massenet's 'Le Cid'; etc.

PLANCUS, Lucius Munatius, Roman politician and soldier: b. Tibur, near Rome, 1st century B.C. He was a pupil of Cicero and an officer under Cæsar in the Gallic war and was shown much favor by that general. After Cæsar's assassination he favored Brutus, but soon deserted to Antony and in 42 B.C. was consul. Later he fell in disfavor with Antony and became a partisan of Octavius. The 7th ode of the first book of Horace is dedicated to him.

PLANE, a popular name for several trees of the genus *Platanus,* which alone constitutes the family *Platanaceæ,* which includes six or seven species, all natives of the northern hemisphere. The American plane, sycamore, button wood, or buttonball (*Platanus occidentalis*), the largest tree of eastern North America, often attains heights of 130 feet and occasionally more than 150 feet. The diameter is frequently more than eight feet. It is a native from Maine to Minnesota and southward to the Gulf States and is a familiar object in low grounds along streams, especially in the Middle States. Its brownish timber is sometimes used for interior finish and often for furniture. The California sycamore (*P. racemosa*) and the Arizona sycamore (*P. Wrightii*) are smaller than the eastern, which they resemble more or less. They are confined to the southwestern States. The name "plane" is often applied to the sycamore maple or great maple (*Acer pseudoplatanus*) because of the resemblance of the foliage to that of the true plane tree.

The Oriental plane is *P. orientalis,* a native of India, southwestern Asia and southeastern Europe. It grows about 80 feet tall, has a rather short, thick trunk and a broad round head; grayish or greenish bark which annually flakes off; large, palmate, deciduous leaves; and monœcious flowers crowded in globular heads, pendulous on long stalks. The bristly fruit-heads persist during the winter. The tree was popularly planted by the Greeks and Romans as an ornament and specimens are still extant which are reputed to be more than 4,000 years old. It thrives best in moist, rich alluvial soil. The timber of young trees is cream-colored; that of old trees brownish. Being fine-grained and easily polished it is popular for cabinet making and for interior finishing.

PLANE, a flat, level surface; *in geometry,* a surface characterized by the property that the straight line joining any two points in it lies wholly in the surface; a level surface. Two such surfaces cannot have three points, not in a straight line, in common without coinciding throughout and any two planes intersect in a straight line. Parallel planes are those whose line of intersection is at an infinite distance, or such as can have a common normal or perpendicular. The angle between two non-parallel planes is that formed by two intersecting straight lines, one in either plane, perpendicular to the line of intersection. There will always be two such angles, each being the supplement of the other, but in ordinary cases the acute one will be most naturally regarded as the angle formed by the planes. One plane is perpendicular to another when the angles thus formed are right angles, or, to put the same thing in a simpler way, when it contains a straight line perpendicular to that other. Three planes will always have one point in common, but this point may be infinitely removed; and they form a solid angle, which is measured in a special way. three mutually perpendicular planes, known as the co-ordinate planes, are used in analytical geometry of three dimensions for determining the position of points in space. See GEOMETRY.

PLANE. See METAL-WORKING MACHINERY; WOOD-WORKING MACHINERY.

PLANE CURVES. See CURVES, HIGHER PLANE.

PLANE-TABLE SURVEYING. See SURVEYING.

PLANET, any world which, revolving about a far larger, central sun, shines principally by light reflected from this sun. Of the nine planets of our solar system, the four inner are solid and the five outer are probably in a gaseous condition and are probably slightly self-luminous. (See EARTH; JUPITER; MARS; MERCURY; NEPTUNE; PLUTO; SATURN; URANUS and VENUS). For such evidence as we have as to the existence of other systems of planets, see COSMOGONY.

PLANETARIUM, in the present accepted meaning, refers to a room or building in which is housed a projecting machine for showing the celestial bodies and their movements. An earlier form of planetarium was the orrery, a device which, by cranking, set the planets in motion around the sun. In a later form, the observer traveled in a cage moving through the heavens along the path of the earth in its orbit. The latest idea of the planetarium is to project images of the celestial bodies on a stationary dome. For this purpose the optical works of the German, C. Zeiss (d. 1888), builds projectors. Several planetariums were built in Germany, and other European cities. The first constructed in the United States was the Adler Planetarium and Astronomical Museum in Chicago, followed by others in New York City, Philadelphia, Los Angeles, and Pittsburgh.

The projecting or audience room is a half-dome 50 feet or more in diameter. The stars can be shown in their positions at any point of time by revolving the projector about an axis parallel with the axis of the earth, so that they appear to rise and set. Sun, moon and planets may also be projected by the intricate mechanism to show their relative positions among the stars. By speeding up the mechanism, long periods of time may be reduced to minutes and thus make relatively slow motions quickly come to pass.

A description of the Hayden Planetarium in New York will serve to add many important details. It was completed and opened in 1935 as a

part of the American Museum of Natural History. For the building, a loan of $650,000 was obtained from the Reconstruction Finance Corporation, and the Zeiss Planetarium instrument was donated by the late Charles Hayden of New York, who also donated the large Copernican Planetarium installed on the first floor of the building. There are two domes, the outer 81 feet in diameter, the inner 75 feet in diameter. The outer is so constructed as to support the weight of the 15-ton inner dome, which serves as the projection screen and in its lower part shows the sky line of the city. For acoustical purposes the inner dome is perforated with tiny holes to allow sound to pass through and be absorbed in the lining of the outer dome. At the centre of the room is mounted the projection instrument «resembling a giant dumbbell about 12 feet long» and containing 120 stereopticon lanterns. It throws lights upon the artificial sky which represents the stars, sun and moon. There are attachments so that any particular part of the heavens may be shown, likewise the positions of the stars at any particular season, and the heavens of a thousand years ago or that of many years hence.

PLANETOIDS. See ASTEROIDS.

PLANIMETER is a machine for determining the area of any plane figure drawn to scale such as maps, sections, diagrams, indicator diagrams. There are two types, «polar» and «rolling.» The polar planimeter invented by Amsler in 1850 consists of two principal parts, viz., the *tracer arm* carrying the tracing point and a carriage with the computing wheel and the *pole arm,* a rod mounted on a pivot on which the instrument revolves. The area of any figure is obtained accurately by tracing its boundary line with the tracing point, reading off the graduations on the measuring wheel and multiplying by a suitable factor to give square feet, square miles or other desired unit. The *hatchet,* planimeter, simplest of all, is a stiff, straight rod with two arms, one of which is pointed, and the other has a hatchet edge. The distance from the centre of this blade to the point is 10 inches. In use the point is made to traverse the periphery of the figure being measured in whole or in part, the blade marking two places between which the distance is measured, and this multiplied by the 10 inches. In the rolling planimeter one of the two rollers actuates the recording mechanism, the measuring wheel revolving against a spherical segment. With the broad roller base the results are not affected by irregularity of the paper. Accordingly it will measure with one operation the area of a figure of any length, the width of which does not exceed the length of the extended tracer-arm. Wider areas can be subdivided by lines and each subdivision measured separately. *The compensating planimeter* is a modification of the polar instrument in which the pole arm is held in the wheel carriage of the tracer arm by a pivot which ends in a steel ball fitting nicely in a socket of the wheel carriage. This gives rigidity and the tracer arm has an angular motion of 180 degrees, or much greater than in old forms. By measuring a figure with pole on the left and then again with pole on the right side of the tracer arm and taking the mean the instrumental errors are compensated. *The pantograph polar planimeter* has two arms, one about seven and one-half inches long for measuring very small figures and one 11 inches long which covers a circle 38 inches in diameter for measuring large figures. The machine is so compensated that when the smaller arm is used the result is more accurate. *The disc planimeter* is another form in which the motion of the measuring wheel is independent of the condition of the paper on which the figure is drawn as the measuring wheel revolves by contact with the plane disc.

For mechanical integrators or integraphs which work on nearly the same principle as the planimeter see INTEGRATORS.

PLANING MACHINE. See METAL-WORKING MACHINERY; WOOD-WORKING MACHINERY.

PLANK, Fort, or **FORT BLANK,** a former fort, of Revolutionary days, located in Montgomery County, N. Y., about two miles northwest from the village of Fort Plain.

PLANKINTON, S. Dak., city and Aurora County seat; alt. 1,528 feet; 23m. W. of Mitchell; on the Chicago, Milwaukee, St. Paul and Pacific Railroad. The county grows wheat and other grains, and engages extensively in livestock raising. Plankinton is a trading center and shipping point; it has grain elevators, and mills. Pop. (1930) 758; (1940) 694.

PLANKTON, a term given by Haeckel to the life, both animal and plant, which occurs floating at the top of lakes and seas, in contrast to the forms on the shores or bottoms. The vegetable element in the plankton is largely diatoms while the animals show a much greater variety. In the fresh waters the plankton is very inconsiderable as compared with that of the sea and to the latter most of these statements apply. The marine plankton consists of both young and adult animals. The adults are largely protozoans, jellyfish, tunisates (especially *Salpa, Doliolum, Pyrosoma, Appendicularia*), together with a few worms. The young include representatives of almost every group of marine animals for the larvæ of many shore or bottom animals are free-swimming for a time. One marked feature of these surface forms is their great transparency and almost total absence of color, except the black pigment in the eyes of the eyed forms.

The plant life of the oceanic plankton includes diatoms, bacteria, blue-green algæ and similar low organisms. The first are especially conspicuous in very cold waters. In some cases the prevailing organism is so abundant that the water is distinctly tinted by it, as in the Red Sea, where a red alga is especially numerous. Many of the plants have powers of locomotion well developed, a feature peculiar to low forms of plant life. The fresh-water vegetable planktons are less noteworthy than the marine because of their smaller extent, the much smaller number of species generally represented, etc. These formations are of particular interest from an economic point of view because they constitute the pastures of the deep. The minute animals feed more or less upon the plant life, great numbers of free-swimming, surface-inhabiting marine animals feed upon the plants or the animals or both, and are in turn the

food of other pelagic animals or birds. At certain seasons the leading forms of the plankton disappear and others take their places. Generally they sink to lower levels to reappear after a more or less definite time. To the student of zoology the plankton is of great interest both from its importance as a food supply for marine forms and as a means of obtaining the larvæ of many animals. It is studied by collecting the life in a net of bolting cloth drawn along the surface and then examining the catch with the microscope. The plankton varies greatly from day to day, and is markedly more abundant at night than in the day. Many of the forms, notably the medusæ, worms and young crustacea, are markedly phosphorescent and to them is due the light in a vessel's wake.

PLANQUETTE, plän-kĕt, **Robert,** French composer: b. Paris, 21 July 1850; d. there, 28 Jan. 1903. He studied at the Conservatoire and with Duprato, gained some popularity by numerous chansons and chansonettes, in 1873 began the writing of operettas and in 1877 achieved a notable success with 'Les Cloches de Corneville,' which ran for 400 performances in Paris, and later as 'The Chimes of Normandy' was almost equally popular in London. It has been often heard in both the French and English versions in the United States. Planquette did not attempt any more serious form of music, but wrote 18 other operettas, including two, 'The Old Guard' (1887) and 'Paul Jones' (1889) for the English stage.

PLANT, Morton F., American financier: b. New Haven, Conn., 18 Aug. 1852; d. 4 Nov. 1918. He was educated at Russell's Military School, New Haven, and in 1868 entered the service of the Southern Express Company at Memphis, Tenn. From 1884 he was connected with the Plant system of railroads, of which he was vice-president until 1902, when the system was merged in the Atlantic Coast Line Railroad Company. Mr. Plant was a director of the Atlantic Coast Line and vice-president of the Chicago, Indianapolis and Louisville Railway and chairman of the board of directors of the Southern Express Company. He was a director of the National Bank of Commerce and trustee of the Connecticut Trust and Safe Deposit Company.

PLANT, in its most general sense, one of the vegetable order of organized things, possessed of life, but not of feeling; in more restricted and popular usage, any small herb, thus excluding the larger shrubs and trees. Originally the term denoted a short, cutting or sapling, as shown by its derivation from the Greek *πλατύς,* broad, Latin *Planus,* flat. In modern times the term has come to denote the building, machinery, fixtures, etc., necessary for the operation of an industry or business, and in a colloquial sense, also denotes a plot or swindle. In this work plants in the botanical sense are treated under Alpine Plants; Beach Plants; Plants, Breeding of; Plants, Classification of; Plants, Diseases of; Embryology of Plants; Fertilization in Plants; Plants, Food of; Plant Geography; Plants, Malformations in; Plants, Migration of; Plants, Morphological Evolution of; Plants, Ornamental; Plants, Physiology of; Plants, Poisonous; Plants, Recapitulation in; Plants, Structure of. See also Agricultural Chemistry.

PLANT-BUG, a bug of any of several families of *Hemiptera,* which obtain their food by sucking the juices of plants through beak-like mouths. The largest group is the family *Coreidæ,* consisting of at least 1,500 species, some of which are dreaded pests of cultivated crops and trees, and the squash-bug (*Anasa tristis*). The *Lygæidæ* include fully 1,300 species, nearly 200 of which are known in America. One of the most widely destructive is the little chinch-bug. The *Pyrrhocoridæ* is a small family, but contains several serious pests.

PLANT CITY, Fla., city in Hillsborough County; alt. 137 feet; 21m. E. of Tampa; on the Atlantic Coast Line, and the Seaboard Air Line railroads; has an airport. It is a shipping center; once a "cotton town," it has come to specialize in shipment of winter strawberries, and it has berry canning plants. Outside the city are phosphate deposits, with a workers' village called Coronet; its recreational grounds are open to Plant City residents. Plant City, incorporated in 1885, was named for Henry B. Plant, railroad magnate; it had previously been called Ichepucksassa (Indian word for tobacco fields), and Cork. Pop. (1940) 7,491.

PLANT GEOGRAPHY. The relation of the plant covering to the surface of the earth is the basis of that division of botany which is called plant geography. This does not confine itself to the geographical distribution of plants, as was formerly the case, but comprises all the out-of-door relations of plants to each other, and to their environment. The subject falls somewhat naturally into several divisions with respect to the point of view. Floristic botany deals with the geographical distribution of species, and with the character of the plant population of different regions and countries. Ecology concerns itself especially with the relation existing between the plant and its environment, and with the grouping of species in particular areas called formations, such as prairie, forest, etc. Experimental ecology is merely a phase of the latter, in which changes in the form and behavior of plants are brought about by changing the physical conditions of the environment. It is of great importance because of its bearing upon the origin of species.

Environment and Plant.—The essential points of inquiry in plant geography are the environment, or home of the plant, usually called habitat by botanists, and the plant, either as an individual, or as a member of the vegetation. The habitat is to be regarded as the cause, the plant as the effect. This is true of the present relation between any habitat and the plants which grow in it only to a certain degree, for probably no plant of the present day owes its entire structure to one habitat. Each habitat, however, does have a modifying influence upon the plants in it. This influence will be great where the physical conditions are extreme, and it will be slight where they are more moderate. In either case this modification will leave its distinctive stamp upon the plant in such a way that one may readily tell whether it grew in pond, meadow, forest or desert. Of the many factors which make up a habitat not all are of the same importance. In some situations

the water of the soil will be most important, in others light will be the controlling factor, while in still other places wind will have the most striking effect. Habitats show great differences also in the amount of water, light, wind and other factors. If one will know the causes of plant structure and distribution, it is necessary to look into the habitat with great care, and to determine the relative importance and the amount of each factor.

The factors of a habitat which are most intimately connected with the form of the plant are those that have to do with the water-supply, and with the food-making activities of the leaf. These are water and light. They have a direct influence upon the plant form, while all others affect the structure indirectly, as a result of their action upon the water of the soil, or the air, or upon light. Every habitat comprises the following factors: water-content, humidity, light, temperature, soil, wind, precipitation, physiography, dead vegetation and animals. Of these, water-content, soil, soil temperature, and physiography belong to the soil, and are in consequence called edaphic. Humidity (air moisture), light, air temperature, wind, and precipitation pertain to the air, and are termed atmospheric or climatic. Dead vegetation and animals are biological or biotic factors. Living vegetation has a marked effect upon its habitat, but this is to be regarded more as a reaction than as a cause.

Water as a Factor.— The simplest plants grow in water, and are in every way dependent upon it. Terrestrial plants — for example, practically all flowering plants and ferns — have adapted themselves to two media, air and water, and their dependence upon water is not so marked. The active root-hairs are still really aquatic, and must always be in contact with an adequate supply of water. The stems and leaves are aerial, but their behavior and form are largely determined by the water in the air, that is, the humidity. The water-supply is used by the root-hairs, while water-loss is the result of evaporation from the surface of the leaves. The excess of supply over loss will determine the form of the plant; it is evident that plants cannot grow where the loss exceeds the supply. The balance between these is so nice that plants grow well only where it is maintained. The most luxuriant vegetation is the forest, where both supply and loss of water are great. An excess of supply over loss is almost as certain to produce stunting and dwarfing, as seen in the plants of ponds and marshes, as is an excessive water-loss, which is the condition typical of deserts and high mountain peaks. The total amount of water present in the soil will vary with the rainfall, and with the behavior of surface and underground streams. Much of the rainfall runs off the surface, while a part of it sinks below the roots and is carried off by underground drainage. What is left remains in contact with the soil-particles as a thin film, and it is this which is absorbed by the root-hairs. The pull exerted by the absorptive power of the hair upon the water-film is greater than the attraction of the soil-particle, and the latter loses its water. If this continues, however, the ratio lessens, and in soils that are drying out the particles hold the water-films with increasing tenacity. In consequence, plants will wilt and die in soils that still contain water. Loose soils, such as sand and gravel, will give up all but 0.5 to 1 per cent of the water-content, while compact clays retain as high as 12 to 30 per cent. An excess of salts in the soil, or a lack of air usually produces a similar effect. They decrease the absorptive power of the root-hairs, and lead to the production in marshes and bogs of plants showing the effects of an insufficient water-supply.

Air Humidity.— The humidity of the air exerts a direct control upon the amount of water evaporated from the leaves. It is evident that the water-loss of the plant will be slight where the amount of moisture in the air is great, and that the evaporation will be great where the air is dry. This effect of humidity is so marked that plants which grow in moist climates often have structures designed to increase water-loss, while those living in desert-like places regularly protect themselves by thickening their epidermis, and decreasing the amount of surface exposed. The relative humidity of lowlands and seacoasts, especially in the tropics, is above 80 per cent; in deserts and upon high mountains it is rarely more than 30 per cent, and often falls below 15 per cent.

Influence of Light.— The amount of light present in a habitat influences directly the food-making activities of the plant. The green coloring matter of plants, the chlorophyll, is formed readily and abundantly only in the light, and the combination of crude materials, water, carbon dioxide, and salts into foods available for the protoplasm can occur only in the presence of this pigment. Light thus bears a peculiar relation to the nutrition and growth of plants, and in a large degree determines their form and size. Sunlight produces vigorous, stocky stems, and thick leaves, as a rule, while plants grown in the shade have tall slender stems, and broad thin leaves. Plants that occur underground, in caves, or grow within organisms, do not develop chlorophyll, and without exception belong to the flowerless forms known as fungi. The intensity of the light varies throughout the day and year; it is greater in the tropics than at the poles, and on the tops of high peaks than at their bases. In forests and thickets the light is often very diffuse, varying from .01 to .003, summer sunlight being 1.

Temperature.— This is directly concerned with the nutrition and growth of plants. Heat is necessary for the germination of seeds, and for the sprouting of bulbs and tubers. It must be present in a considerable degree for the food-making activities of plants, and upon it in a large part depends the size of individuals, and the luxuriance of vegetation. The growing period is the season during which temperatures favorable to plant growth prevail; the length of this period determines in great measure the native vegetation of a country, and the cultivated plants which can be grown there. Indirectly, temperature exerts a pronounced effect upon the form of plants, by decreasing the moisture of the air, and thus increasing the water-loss. In tropical and subtropical deserts this indirect action of heat is a predominant factor. Soil temperatures are of much less importance, though they have much to do with germination and the activity of underground parts.

Wind Effects.— Wind influences plant life both directly and indirectly. Its mechanical action is marked in regions where forceful and constant winds prevail, notably seacoasts and high mountain peaks. Shrubs and trees become bent or prostrate, and their branches are developed almost wholly on the leeward side. Over great open stretches where strong winds prevail, for example prairies and steppes, the plant forms are largely grasses and grass-like plants, which are not easily torn or whipped by the wind. As is well-known, winds play an extremely important part in carrying the pollen of trees and grasses, and in scattering seeds and spores. Like heat, wind decreases the humidity of the air, and correspondingly increases the evaporation from leaf-surfaces. It does this by removing the more or less saturated air in contact with the plant, replacing it with air containing less moisture. This action is characteristic of the dry southwest winds in the corn-belt, which rapidly carry away the moisture of the leaves, causing the latter to curl, thus decreasing the surface and affording some measure of protection. The stunted forest vegetation of arctic and alpine timber-lines is largely due to the drying action of almost constant winds. The direction, force, and duration of the wind must all be taken into account in the study of vegetation.

Soil Action.— The soil acts directly upon the behavior and form of plants by reason of its influence upon water-content and temperature. In plant geography, all inorganic strata upon which plants grow are termed soils. The extreme types are rock and water, between which are found all manner of gradations from gravel to mud. The weathering of rocks produces two kinds of soils quite different in their behavior with respect to water. The one is loose and composed of large particles — for example, sands and gravels; the other is composed of fine, compact particles, clays and loams. Sands and gravels absorb nearly all of the rain falling upon them but much of the water taken up passes through and is carried away along some impervious stratum. What remains as water-content is readily absorbed by the root-hairs or is lost by evaporation from the soil. On account of the large air-spaces between the grains, the water in the lower layers is raised with difficulty by capillary action. Plants withdraw from loose soils nearly all of their water-content. Compact soils, especially clay do not absorb rain rapidly, and much of the latter is carried away by surface drainage. Water once absorbed is held tenaciously, and the loss by underground drainage is slight. The pores of the soil are fine, and capillarity plays an important part in raising water from the lower levels. The particles attract the water-films strongly, and in consequence clay yields its water to plant or air very slowly. Ordinary plants will wilt in clay soils which still contain as high as 12 to 30 per cent of water. Rock is all but absolutely impervious to water. Mosses and lichens alone can grow upon it, in consequence of their power to decompose the surface and their ability to withstand drying out. The amount of soluble material in the soil has a direct effect upon the growth of plants. Nearly all ordinary soils contain an adequate supply of soluble minerals; a few, however, are deficient in these, and are unable to support more than a scanty vegetation. Other soils contain in excess soluble salts and acids which are harmful. The sparse, desert-like vegetation of salt basins and alkali wastes is due to the large quantities of sodium chloride, sodium carbonate, and other salts present. In swamps and bogs the decay of plant and animal remains uses up the available oxygen and thus hinders the absorptive powers of the roots. The kind of material in the soil and the fineness and compactness of the grains determine its behavior with reference to the absorption and radiation of heat. The color of the soil, the amount of water present, and other conditions have also to do with this matter. Rock is warmed most readily in the sunshine, and at night most readily parts with its heat. Water is at the other extreme; it warms up slowly and, conversely, yields its heat reluctantly.

Utilization of Moisture.— It is a well-established fact that plants in general are unable to absorb water-vapor from the air. The moisture must be condensed into water, and then must regularly find its way into the soil before it can be used by the plant. A comparatively small number of plants, lichens, mosses, and tree-dwelling orchids absorb rain or dew directly through their leaf or thallus surfaces, but with the great majority of plants the water can only be taken in from the soil or substratum. The moisture of the air is condensed or precipitated in various forms — rain, dew, snow, sleet, hail, frost and fog. With the exception of the last, all of these contribute sooner or later to the water-content of the soil, the important difference being that the solid forms usually melt gradually and are in consequence absorbed more completely. The water which falls upon the surface of the soil is partly absorbed, and partly carried away by drainage. The latter is known as "run-off"; its amount will depend upon the compactness of the soil and the steepness of the slope. The absorbed water passes into the lower layers in part, where some of it is drained off as gravitation water, and some is retained as capillary water to be raised by pillary action into the upper layers of the soil. That which remains in the soil about the roots forms thin films about the soil-grains, and is known as the water-content. This alone can be used by the root-hairs. Part of it, however, is lost by direct evaporation from the soil. Rain has little or no mechanical action upon plants, except perhaps in the tropics, where it falls in torrents. In the form of "run-off," however, it acts powerfully upon the surface of hills and mountains, and plays in consequence an extremely important part in the development of vegetation. Sleet and hail are very destructive in the breaking of twigs and branches and the cutting and tearing of leaves, but are of little importance because of their relative infrequence. Snow, on the other hand, has had a great deal to do with the forms of trees, particularly the pines, spruces, and firs, in northern and mountain regions. It is a poor conductor, and for this reason affords much protection to plant parts covered by it. Unlike rain, it is often unequally distributed by the wind, and therefore produces important local differences in the water-content of the soil.

Physiography.— The surface features of a region — its physiography — affect directly sev-

eral of the physical factors of habitats. Altitude not only influences the rainfall, but it also increases water-loss by reason of the reduced air-pressure and the decreased humidity. The sunlight may be stronger, as the rays pass through fewer air-layers, and are absorbed in a less degree. The degree of slope is especially important, as it determines very largely the ratio between "run-off" and absorbed water. In mountain regions particularly, it modifies the angle at which the sun's rays strike the surface, and increases the amount of heat and light received. The exposure of the surface, that is, the direction in which it lies, affects the amount of heat and light, the intensity of the wind, and the snowfall. Furthermore, the character of the surface itself, whether level or uneven, will influence all of these factors in a less degree. Physiographic changes, such as elevation and subsidence, the erosion of river-valleys, and the upbuilding of swamps, deltas, etc., have a profound effect upon the distribution of plants, and the development of vegetation.

Vegetable, Animal and Human Factors.— Dead vegetation increases the water-content of a habitat by checking the movement of the "run-off," and thus increasing the absorption, and by protecting the surface of the soil from excessive evaporation. It equalizes the soil temperature by hindering the warming action of the sun's rays, and the cooling effect of radiation. It also diminishes the force of the wind, and, finally, by decay, returns to the soil much of the nutrient material taken from it. Living vegetation has the same effect, but is different in that it constantly draws water and nourishment from the soil, and often reduces the amount of light present. The activities of animals and man are extremely diverse. Earthworms and burrowing mammals enrich the soil by working it over repeatedly. Grazing animals have more or less effect upon grasslands. Insects are fundamentally important in fertilization, and doubtless often act decisively in the struggle for existence by destroying some plants and not others. Man is a biological factor of the first importance, even if we leave out of consideration all the changes that he has brought about in plants and vegetation in consequence of cultivation. He changes habitats fundamentally by the removal of forests, by fires, by the construction of railroads and canals, by drainage, by irrigation, etc.

Classification of Habitats.— Habitats are usually grouped with respect to the two direct factors, water and light. They are first classed as wet, moist and dry and the moist habitats are further divided into sun and shade. Wet habitats comprise all bodies of water, oceans, lakes, ponds, springs, streams, swamps, marshes, river-banks, seashores, tanks, etc. Dry habitats are principally deserts, sandhills, prairies, gravel-slides, strands, dunes, bad lands, cliffs, rocks, heaths, humus-marshes, moors, alpine and polar barrens. Sunny moist lands are meadows, pastures, grain-fields and waste places. Shady moist habitats are forests, groves, woodlands and thickets.

Effects of Habitat.— These, as regards the individual, are either evident or demonstrable, as in the case of the habitat form seen in bog-plants, shade-plants, etc., or they are obscure and remote and can in consequence no longer be traced. The latter is true of vegetation forms — trees, shrubs, bulb-plants, etc. Three well-defined groups of habitat forms are recognized, based upon the water-content of habitats. These are water-plants (hydrophytes), moist-land or middle plants (mesophytes), and desert plants (xerophytes). Upon the basis of light differences, mesophytes are further divided into sun-plants (heliophytes), shade-plants (sciophytes) and darkness-plants (scotophytes). Water plants owe their peculiar stamp to the fact that the water-supply is always greatly in excess of the water-loss. The roots are superficial in position, owing to the abundance of water at or on the surface of the soil. Root-surfaces are slightly developed and root-hairs often lacking, because the amount of water renders absorption easy. The surplus of water is a disadvantage, however, as it reduces the amount of air in the soil and hence cuts off the supply of oxygen necessary for the activity of the roots. This lack of aeration is compensated by the development of large air-passages leading down from the leaves through the stem and roots. Stems and leaves are almost invariably smooth and without any sort of protective covering. Breathing-pores are usually abundant and the necessity that the plant should lose a large amount of water has led to the development of water-pores and papillæ. This structure is typical of amphibious plants, that is, those that grow in the mud or in shallow water. Floating plants are usually much the same, with the exception that the breathing pores become useless and disappear on the under surface of the leaf, which is in contact with the water. Certain plants, such as the duckweed, have become greatly reduced in consequence of the floating habitat, and consist merely of a tiny, leaf-like disc, with a few rootlets. Submerged plants grow entirely beneath the water and are not subject to water-loss. As a result their leaves and stems are greatly reduced. The leaves are thin and divided into narrow segments; in structure they are almost uniform. The characteristic air-passages of the other water forms are lacking, as all the air must be dissolved in water.

Desert-plants are in most respects the exact opposites of water-plants. Not only is the water-supply scanty, but all the factors which increase water-loss are present in a large degree. Such plants must use all their power of adaptation to absorb and store all the water they can and to lose just as little by evaporation as possible. The roots of desert-plants are for the most part deep-seated and branch for the most part only in the deeper, moist soil. They are covered elsewhere with a corky layer to prevent the loss of water where the root passes through the dry upper layers. In the moist soil, root-hairs are produced in large numbers. In many cases the upper portion of the root consists of tissue especially adapted to the storage of water. The stems of xerophytes are short and stout. The leaves are thick and much reduced in size; and in extreme forms they are entirely lacking. Both leaves and stems are covered with a thick coating of hairs, or wax, or the epidermis is greatly thickened, all for the purpose of protection against water-loss. The breathing-pores are generally confined to the underside of the leaf and are often sunken far

below the surface for still greater protection. In the cactus the leaves are reduced to mere scales and the stem often contracted into a cylinder or ball, thus decreasing the exposed surface to the minimum. Succulent plants, such as the live-for-ever and ice-plant have, on the other hand, been modified so that the leaves serve for the storage of water. Lichens and mosses which grow on rocks are capable of withstanding extreme dryness, a faculty seemingly inherent in their protoplasm, as they are without ordinary protective contrivances.

Moist-land plants, or mesophytes, stand as intermediate between the two preceding groups. The water-supply, though not excessive, is usually sufficient, and the humidity of the air is great enough to preclude the danger of excessive water-loss. In consequence, mesophytes have well-developed, more or less branched, root-systems, which are usually intermediate in position, but many of them are deep-seated. The development of surface is moderate, as well as that of the protective cork. Stems are for the most part tall and vigorous and much-branched. The leaves are large and mostly entire, or at least rarely finely dissected. Hairs are common, but seldom compacted into a dense covering. The epidermis is not greatly thickened and while the breathing-pores are often more abundant on the lower side, they are present in large numbers on both surfaces. The leaves of mesophytes are characterized regularly by compact rows of oblong cells placed at right angles to the surface, which are called palisade-tissue, and by loose irregular cells with large intercellular spaces, the sponge tissue. The former is usually in the upper, the latter in the lower half of the leaf. The palisade is differentiated in response to the action of strong light, while sponge-tissue results from the need of the rapid diffusion of the carbon dioxide and oxygen absorbed from the air.

Sun-plants and shade-plants are especially different in their leaves; this is to be expected, as the leaf is the organ most dependent upon light. The root-system will be more superficial in shade-plants, as the moisture is nearer the surface of the soil in shaded than in sunny places. The stem will be more slender, taller and often more branched, since it is necessary to place the leaves in the position to receive the most of the diffuse light. The leaves are broad, thin and entire, increasing the exposed surface, while in sun-plants they are thick and more or less divided. In typical shade-leaves, the palisade-tissue is reduced to a single row, or is altogether absent. The cells are not crowded closely and their longest axis often coincides with the epidermis of the leaf. Sun-leaves have one or more rows of typical palisade on the upper side and are frequently palisaded on the lower side also. The epidermis develops more wax and hairs in the sun; the breathing-pores are more numerous on the lower than upon the upper surface, while there is little difference in the shade.

Origin and Distinction of Forms.— Vegetation-forms doubtless originated in response to physical conditions, but this relation is hardly evident to-day. We can only see in trees, shrubs, herbs, etc., an expression of the success which different plants have obtained in the struggle for existence. It is also evident that the vegetation form of a plant has much to do with its persistence and hence with its importance in vegetation. The main groups of vegetation-forms are woody plants, herbs and thallus (flowerless) plants. The former are the largest, the most dominant, and the most persistent of all forms; the latter are tiny, subordinate and fleeting. The various woody forms are trees, shrubs, bushes and climbers; the first are the most important, the last the least so. Trees constitute the most permanent type of vegetation, the forest, to which shrubs, bushes and climbers also contribute. The relation between these forms is easily seen in the development of a forest, in which bushes precede and are followed by shrubs; these give way to the trees, the climbers coming in after the latter.

Herbs are specially distinguished from woody plants by their lack of woody stems and by the fact that their persistent parts are underground. They can never be very large, for their stems lack support, though they may persist for years. They are either perennial, blooming each year, or annual-biennial, blooming at the end of the first or second year, and then dying. Various forms of herbs are distinguished with reference to the position of the stem and leaves. In some, like the dandelion, the leaves are grouped in rosettes in response to light and heat. In others, such as the everlasting, the plants are set close together for somewhat similar reasons and perhaps for mutual protection also. Climbers, sweet peas, vetches, etc., develop partly for increased support, partly to secure more light. Grasses form sod because of their abundant rootstalks; it is this faculty which enables grasses to control the vegetation of meadows and prairies. Bunch-grasses are an exception, but they generally grow where the formation of a sod is impossible on account of unfavorable physical conditions. The position and abundance of herbs in a formation will depend also upon the character of the underground parts. Species with underground runners or rootstalks will be more abundant and more widely distributed than those with nearly stationary bulbs or tubers. The vegetation forms of thallus plants play a very subordinate rôle in vegetation. Mosses, liverworts and lichens are regularly present in tree and herb formations, but their small size and transient nature make them of little importance. They are significant of the early stages of vegetation on rocks, new soils, etc., but they soon disappear before the grasses and other herbs. Fungi are entirely dependent upon their host plant or stratum and are relatively insignificant, except where they are necessary to the nutrition of the host, as in the case of certain trees.

Plant Formations.— The vegetation of the earth's surface is not at all uniform, but consists of a large number of different areas, determined by climate and soil. The most extensive of these are known as formations, illustrated by the deciduous forest of the Mississippi Basin, the prairie-plains grassland, and the sage-brush desert of the Great Basin. Each formation is the product of a particular climate and hence represents the highest type of vegetation possible under it. For this reason, each formation is often called a climax or climax formation. The entire plant covering of the globe is

made up of such climax formations. These are far from continuous or uniform, however, owing to the interruptions due to bodies of water, outcrops of rock, fire, cultivation and other disturbances. In such areas are to be found pioneer communities which develop through a series of stages until the final stage or climax for that particular climate is reached. Thus, each formation consists of two kinds of communities, developmental or successional ones which disappear in turn until the final stage is reached, and climax ones which persist for long periods and over vast areas as long as the climate remains essentially the same. The climax divisions of a formation are known as associations, consociations and societies, and are well illustrated by the grassland formation which covers the prairies and plains. The tall grasses of the prairie constitute one association made up of consociations of *Stipa, Agropyrum* and *Koeleria,* while the short grasses form a plains association consisting of the *Bouteloua* and *Bulbulis* consociations primarily. The societies are due to the presence of characteristic perennial herbs such as *Amorpha, Psoralea, Aster, Solidago,* etc., which dominate more or less distinct areas within the association.

Areas or Formations.— The vegetation of the earth's surface is not at all uniform, but consists of a multitude of different areas, each corresponding to a habitat. These areas are called formations and each is composed of an association or groups of plants determined by the physical factors of its habitat. A pond will be occupied by a community composed of water-plants; a forest formation will consist of mesophytes, and desert plant formations will be found in dry, sandy regions. Even within each formation it will be found that the plants are not uniformly distributed; some will occur in masses, while others are scattered singly, and one species will be met again and again, while another will be found but once. Furthermore, communities are not fixed groups of plants. One species will find that the conditions of life become more and more difficult; and will gradually disappear. Other species will prosper and increase rapidly in number, this very prosperity often producing the conditions unfavorable to another. The seeds of species from other places will be brought in by the wind, by birds or by animals, and will find a new home, or, after struggling for a while, the plants will disappear. Frequently, new plants come in to such a degree that they finally replace the original species entirely and the community is replaced by a new one.

The development of a formation may be readily followed where rocks are disintegrating, or where an original vegetation has been removed by fire. In the first case, the pioneer plants are small crust-like lichens, which decompose the surface of the rock, and by their decay prepare a thin soil for the larger leaf-like forms, which sooner or later appear. With these usually enter the rock mosses and the two by their activity and ultimate decay finally form a soil sufficient for some of the grasses and other herbs which are able to withstand extreme dryness. Meanwhile, the action of rain and frost has produced rifts in the rocks, which are first filled with mosses, and then by a soil deep enough to support larger plants. The ultimate result of the activity of these various factors is the breaking down of the rock into soil. In the case of the harder rocks, this will be a coarse sand or gravel; with the softer ones, it is a fine sand or marl. At this stage, leaf-like lichens and mosses play some part in binding the soil particles together, but they soon disappear before the grasses, which in their turn yield in a few years to other herbs. These are sooner or later displaced by bushes and shrubs and the latter make way for the trees which mark the close of the process. Such a primary succession takes place very slowly and may often extend over a century or more. When a forest is burned, the revegetation is much more rapid, as the soil is already prepared and the succession is termed secondary. Tiny mosses and fungi first appear and in a year or two at the most are replaced by low herbs. These disappear before the invasion of grasses and "fireweed," and these are replaced by fast-growing trees, such as the birch and the aspen. Such trees are usually shortlived and are displaced after a decade or so by pines, spruces or firs, which in many cases are at last conquered by the hardwoods. It is significant of the plants of each stage of such successions that they bring about conditions in their action upon the habitat which finally cause their own disappearance. Each stage represents a community, but the change from one stage to the next takes place so slowly that it is not at all uncommon to find associated with the plants typical of one stage some survivors of the preceding community, as well as a few pioneers of the next stage.

Migration of Plants.— The movement of plants in vegetation is known as migration. In the case of the simple water-plants, the algæ, the whole plant moves of its own accord, or is carried by some agent. The same holds for a few of the flowering plants of floating habit. All terrestrial plants are fixed, however, and migration must act regularly upon the spore or seed. In tumbleweeds, the whole plant is frequently carried away by the wind, but it is no longer in a living condition. Spores are readily scattered by the wind on account of their lightness, but seeds and fruits have been especially modified for migration on account of their greater weight. Plants growing in or near the water often have fruits with corky or inflated envelopes, which serve to keep them afloat. The great majority of the modifications for securing migration, however, are concerned with wind and animals. In the former, the contrivances are uniformly for the purpose of lightening the fruit or seed, so that it may readily be carried by the wind. Fruits that are to be distributed by animals are provided with spines, hooks or glands for attachment, or are made attractive by a bright or edible envelope. Wind-carried fruits are especially common; they are provided with wings, as in the maple; with hairs, as in the milkweed, and with parachute-like tufts, as in the dandelion. Man plays the most important part of all distributive agents, if voluntary as well as involuntary carriage be considered. He has carried cultivated plants and weeds all over the globe and to thousands of places where they could never have gone of themselves.

The movement of the seed or fruit of a species into a new formation or country is often

PLANTS OF GREAT COMMERCIAL VALUE

determined by natural barriers. Winds bear seeds for long distances, but they are powerless to carry them across oceans, or over high mountain ridges. Similarly, a desert region is a barrier to seeds brought from a moist climate, and a cold climate prevents the naturalization of species coming from a warm country. The chance that seeds will germinate and grow is greatest when they are carried into a habitat similar to the original one and it is least when they are left in habitats very different from it. It is unquestionable that seeds have often been carried into many places where they were unable to secure a foothold. This fact explains why many species are found only in certain countries, or localities, and why it is that each formation retains a more or less distinctive impress.

North American Vegetation.— The vegetation of the North American continent owes its general features to the gradual decrease of heat to the northward, and the more or less constant decrease in the rainfall in passing from the coasts to the interior. The greatest development of forests is found in the warm coast-regions of the southeast, and of the Pacific. The poorest vegetation is found in the north, and on high mountains, where the temperatures are low, and in the interior where the rainfall is slight. The character and distribution of vegetation are chiefly determined by heat and water. As a result, the vegetative covering falls into zones corresponding in a general way to zones of temperature. If the distribution of moisture were uniform over the continent, the series of zones would be as follows: (1) the zone of evergreen tropical and subtropical trees; (2) the zone of deciduous trees; (3) the zone of cone-bearing trees; (4) the zone of grasses and other herbs; (5) the zone of mosses and lichens; (6) the zone of ice and snow. The rainfall decreases regularly from the coast inland, while a high mountain range makes an abrupt change in the amount. The Appalachian, Rocky Mountain and Sierra Nevada ranges act as barriers to the passage of moisture-laden winds, and turn into grass land or desert, regions that are sufficiently warm to be forested. The Appalachian barrier is too low to be very effective, and the forests yield to prairies only slowly and far inland. The Sierra Nevada and the Rocky Mountains are almost complete barriers, and they enclose a parched desert. The height of these ranges causes an abundant condensation on their slopes, and in consequence they are more or less heavily wooded. On account of the altitude, the temperature is low, and the forests are merely southerly extensions of the great boreal zone of pines and spruces. A general survey of the North American continent would show it to be wooded on the eastern, western, and southern coasts. In the north, there is a zone of grass and moss-covered barrens. In the interior there is a region of plain and prairie, stretching unbroken from Athabasca to Texas, and between the two great Cordilleran ranges from Washington to Central America lies a great desert region, broken repeatedly by intersecting lines of mountains. Running southward from the great northern forest mass of the continent are the three mountain systems. In the low Appalachian system, the arctic vegetation of the north is found on a few alpine peaks alone, but in the higher Rocky Mountains and the Sierra Nevada this long southward extension of dwarf herbaceous vegetation is almost continuous. All carry the northern pines and spruces far south, but in the lower range, these disappear in Virginia, while on the higher ranges they persist almost to the Mexican boundary. North America is thus seen to be covered with belts of vegetation running east and west, which are completely interrupted in the interior by high mountain ranges, which, together with the Appalachians, also serve to carry the northern forests southward in three long tongues.

PLANTAGENET, plăn-tăj'ĕ-nĕt, a family whose various branches occupied the throne of England from the reign of Henry II (1154) until the accession (1485) of Henry VII, the representative in the female line of the Lancastrian branch of it, who, by his marriage (1486) with Elizabeth of York, daughter of Edward IV, representative of the York branch, united its various branches in the house of Tudor, of which he was the direct descendant. On the death of Henry I the Crown was claimed by his daughter, Maud or Matilda, first married to Henry V, emperor of Germany, and afterward to Geoffroi V, Count of Anjou, surnamed Plantagenet, on behalf of her son by the latter, Henry Plantagenet. Stephen obtained it during his lifetime and was succeeded on his death by Henry, who became the first of the Plantagenet kings. The name is said to have been derived from the circumstance of the Count of Anjou wearing a branch of broom (*plante de genêt*) in his cap. The direct line became extinct in Richard II (1399), before whose death the Crown was usurped by Henry IV, son of John of Gaunt, Duke of Lancaster, 4th son of Edward III, in prejudice of Edmund and Anne Mortimer, the descendants of Lionel, Duke of Clarence, 3d son of the same Edward. He was succeeded by his descendants, Henry V and Henry VI, and during the reign of the latter, Edmund Mortimer having died without heirs, Richard, Duke of York, son of Anne Mortimer, who had married the heir of Edmund, Duke of York, 5th son of Edward III, claimed the Crown. This occasioned the wars of the Roses, which terminated in the accession of Henry VII, as above mentioned. See ENGLAND, *History;* and articles on individual monarchs.

PLANTAIN, several species of *Plantago,* a genus of the family *Plantaginaceæ.* Most of the 200 or more widely distributed species are weedy herbs or subshrubs. The best known species is the common dooryard plantain (*Plantago major*), abundant in most of North America. It is a native of Europe, but was spread so rapidly by human agencies in America that the Indians sometimes called it «white man's foot.» The leaves are sometimes used as pot herbs. Another well-known species is English, or «black plantain» (*Plantago lanceolata*), in America a pernicious lawn weed, but sometimes used in Europe upon sterile and dry soils

as a fodder plant, the hot, dry summers favoring its growth in the United States and reducing the resistance of the grass. The only safeguards against it are thorough preparation and enrichment of the ground before planting to lawn, careful selection of pure lawn-grass seed and persistent care both in annual attention to the needs of the grass and the weeding. The seeds are used for bird-feeding. Numerous species are natives of North America.

PLANTAIN, Adam's Fig, or **COOKING BANANA,** a tropical herb of the family *Musaceæ,* regarded as the parent species, *M. paradisiaca* to which, as the subspecies *sapientum,* belong the most of the common thick-skinned yellow bananas sold in the world's markets. A native of India, it has been taken to all tropical countries and cultivated. The true *M. paradisiaca is* not eaten without cooking. Varieties of the subspecies are commonly eaten raw. In propagating them, suckers or cuttings are used; the former being removed from the parent plant with attached roots, the cuttings (of the root stock) being rooted in a bed, and set out when they have formed two leaves. Plantains succeed best in moist, rich soil. When about 18 months old they should bear a cluster of fruits, after which the stalk dies and new sprouts take its place and so continue for years.

PLANTAIN-EATERS, a family (*Musophagidæ*) of African picarian birds, classified near the cuckoos, with notched or saw-edged bills and usually of brilliant colors. The genus *Musophaga,* in which the base of the bill spreads over the forehead like a broad plate, includes the most typical West African forms. These birds feed chiefly upon the fruit of the banana and plantain. The typical plantain-eaters belong to the genus *Corythaix* which has but two species. The genus *Turacus,* which has 23 species, comprises the most commonly known members of the family. They have a bill of the ordinary type and an erectile crest. The general color is green, with red quills in the wings and tail. Insects form part of their food and they appear notably tame in habits, even in a wild state. They average the size of the common pigeon or crow, or a little larger. Consult Knowlton, F. H., 'Birds of the World' (New York 1909).

PLANTATION, a term anciently used to designate a colony. Plantations, according to Blackstone, are colonies where the lands are claimed by the right of occupancy only, by finding them desert and uncultivated, and peopling them from the mother country; or where, when already cultivated, they have been either gained by conquest or ceded by treaties. The term came into use in the United States in colonial times and is still preserved in the official title of the State of Rhode Island, namely, "Rhode Island and Providence Plantations." The plantations of the southern United States were the chief centres of aristocracy before the emancipation of the negro slaves. Changing conditions are rapidly wiping out the old-time plantation, which is characteristic of agricultural countries, and disappears in the march of industry. The word plantation became popular in an extended and different meaning in the South, where it is still used to designate a large section of cultivated land; the estate of a large landed proprietor — equivalent to the "ranch" of the western United States or the hacienda of South America.

PLANTIGRADE ANIMALS, those which in stepping place the heel and whole sole of the foot upon the ground, for example, bears; as opposed to *digitigrade* animals, for example, cats, dogs, which step upon their toes. The term was applied by Cuvier to a section (*Plantigrada*) of the *Carnivora,* but has now no significance in classification.

PLANTIN, plăn-tăn, **Christophe,** French printer: b. Saint Avertin, France, 1514; d. Antwerp, 1 July 1589. He established at Antwerp in 1555 a printing press which became famous for the character of the work produced and later founded presses at Leyden and Paris. His most celebrated work is the 'Biblia Polyglotta' (8 vols., 1568–73). His office in Antwerp was purchased in 1877 by the city and now constitutes the Musé Plantin-Moretus. Consult 'Life' by Rooses (1892).

PLANTS, Breeding of. *Fundamental Principles.*— Only the most limited view of plant-breeding can be given in an ordinary thesis. It would be necessary to extend the subject through many volumes to give even a general view of what has already been demonstrated, and that which the clear light of science has yet to bring forth from the depths is too extensive even for the imagination to grasp, except through a full knowledge of what practical field-work has already accomplished.

The fundamental principles of plant-breeding are simple, and may be stated in few words; the practical application of these principles demands the highest and most refined efforts of which the mind of man is capable, and no line of mental effort promises more for the elevation, advancement, prosperity and happiness of the whole human race.

Every plant, animal and planet occupies its place in the order of Nature by the action of two forces — the inherent constitutional life-force with all its acquired habits, the sum of which is heredity; and the numerous complicated external forces or environment. To guide the interaction of these two forces, both of which are only different expressions of the one eternal force, is, and must be, the sole object of the breeder, whether of plants or animals.

When we look about us on the plants inhabiting the earth with ourselves, and watch any species day by day, we are unable to see any change in some of them. During a lifetime, and in some cases perhaps including the full breadth of human history, no remarkable change seems to have occurred. And yet there is not to-day one plant species which has not undergone great, and to a certain extent constant change.

The life-forces of the plant in endeavoring to harmonize and adapt the action of its acquired tendencies to its surroundings may, through many generations, slowly adapt itself to the necessities of existence, yet these same accrued forces may also produce sudden, and to one not acquainted with its past history most surprising and unaccountable, changes of character. The very existence of the higher orders

of plants which now inhabit the earth has been secured to them only by their power of adaptation to crossings, for through the variations produced by the combination of numerous tendencies, individuals are produced which are better endowed to meet the prevailing conditions of life. Thus to Nature's persistence in crossing do we owe all that earth now produces in man, animals or plants; and this magnificently stupendous fact may also be safely carried into the domain of chemistry as well, for what is common air and water but Nature's earlier efforts in that line, and our nourishing foods but the result of myriad complex chemical affinities of later date?

Natural and artificial crossing and hybridization are among the principal remote causes of nearly all otherwise perplexing or unaccountable sports and strange modification, and also of many of the now well-established species. Variations, without immediate antecedent crossing occur always and everywhere from a combination of past crossings and environments, for potential adaptations often exist through generations without becoming actual, and when we fully grasp these facts there is nothing mysterious in the sudden appearance of sports; but still further intelligent crossings produce more immediate results and of great value, not to the plant in its struggle with natural forces, but to man, by conserving and guiding its life-forces to supply him with food, clothing and innumerable other luxuries and necessities. Plant-life is so common that one rarely stops to think how utterly dependent we are upon the quiet, but magnificently powerful work which they are constantly performing for us.

It was once thought that plants varied within the so-called species but very little, and that true species never varied. We have more lately discovered that no two plants are ever exactly alike, each one having its own individuality, and that new varieties having endowments of priceless value, and even distinct new species, can be produced by the plant-breeder with the same precision that machinery for locomotion and other useful purposes are produced by the mechanic.

The evolution and all the variations of plants are simply the means which they employ in adjusting themselves to external conditions. Each plant strives to adapt itself to environment with as little demand upon its forces as possible and still keep up in the race. The best-endowed species and individuals win the prize, and by variation as well as persistence. The constantly varying external forces to which all life is everywhere subjected demand that the inherent internal force shall always be ready to adapt itself or perish.

The combination and interaction of these innumerable forces embraced in heredity and environment have given us all our bewildering species and varieties, none of which ever did or ever will remain constant, for the inherent life-force must be pliable or outside forces will sooner or later extinguish it. Thus adaptability, as well as perseverance, is one of the prime virtues in plant as in human life.

Plant-breeding is the intelligent application of the forces of the human mind in guiding the inherent life-forces into useful directions by crossing to make perturbations or variations and new combinations of these forces, and by radically changing environments, both of which produce somewhat similar results, thus giving a broader field for selection, which again is simply the persistent application of mental force to guide and fix the perturbed life-forces in the desired channels.

Plant-breeding is in its earliest infancy. Its possibilities, and even its fundamental principles, are understood but by few; in the past it has been mostly dabbling with tremendous forces, which have been only partially appreciated, and it has yet to approach the precision which we expect in the handling of steam or electricity, and, notwithstanding the occasional sneers of the ignorant, these silent forces embodied in plant-life have yet a part to play in the regeneration of the race which by comparison will dwarf into insignificance the services which steam and electricity have so far given. Even unconscious or half-conscious plant-breeding has been one of the greatest forces in the elevation of the race. The chemist, the mechanic have, so to speak, domesticated some of the forces of Nature, but the plant-breeder is now learning to guide even the creative forces into new and useful channels. This knowledge is a most priceless legacy, making clear the way for some of the greatest benefits which man has ever received from any source by the study of Nature.

A general knowledge of the relations and affinities of plants will not be a sufficient equipment for the successful plant-breeder. He must be a skilful botanist and biologist, and having a definite plan, must be able to correctly estimate the action of the two fundamental forces, inherent and external, which he would guide.

The main object of crossing genera, species, or varieties is to combine various individual tendencies, thus producing a state of perturbation or partial antagonism by which these tendencies are, in later generations, dissociated and recombined in new proportions, which gives the breeder a wider field for selection; but this opens a much more difficult one — the selection and fixing of the desired new types from the mass of heterogeneous tendencies produced, for by crossing bad traits as well as good are always brought forth. The results now secured by the breeder will be in proportion to the accuracy and intensity of selection, and the length of time they are applied. By these means the best of fruits, grains, nuts and flowers are capable of still further improvements in ways which to the thoughtless often seem unnecessary, irrelevant or impossible.

When we capture and domesticate the various plants, the life-forces are relieved from many of the hardships of an unprotected wild condition, and have more leisure, so to speak, or, in other words, more surplus force, to be guided by the hand of man under the new environments into all the useful and beautiful new forms which are constantly appearing under cultivation, crossing and selection. Some plants are very much more pliable than others, as the breeder soon learns. Plants having numerous representatives in various parts of the earth generally possess this adaptability in a much higher degree than the monotypic species, for having been subjected to great variations of soil, climate and other influences, their continued existence has been secured only by the inherent habits which adaptation demanded, while

the monotypic species not being able to fit themselves for their surroundings without a too radically expensive change, have continued to exist only under certain special conditions. Thus two important advantages are secured to the breeder who selects from the genera having numerous species — the advantage of natural pliability, and in the numerous species to work upon by combination for still further variations.

The plant-breeder before making combinations should with great care select the individual plants which seem best adapted to his purpose, as by this course many years of experiment and much needless expense will be avoided. The differences in the individuals which the plant-breeder has to work upon are sometimes extremely slight. The ordinary unpractised person cannot by any possibility discover the exceedingly minute variations in form, size, color, fragrance, precocity and a thousand other characters which the practised breeder perceives by a lightning-like glance. The work is not easy, requiring an exceedingly keen perception of minute differences, great practice, and extreme care in treating the organisms operated upon, and even with all the naturally acquired variations added to those secured by scientific crossing and numerous other means the careful accumulation of slight individual differences through many generations is imperative, after which several generations are often, but not always, necessary to thoroughly "fix" the desired type for all practical purposes.

The above applies to annuals or those plants generally reproduced by seed. The breeder of plants which can be reproduced by division has great advantage, for any valuable individual variation can be multiplied to any extent desired without the extreme care necessary in fixing by linear breeding the one which must be reproduced by seed. But even in breeding perennials the first deviations from the original form are often almost unappreciable to the perception, but by accumulating the most minute differences through many generations the deviation from the original form is often astounding. Thus by careful and intelligent breeding any peculiarity may be made permanent and valid new species are at times produced by the art of the breeder and there is no known limit to the improvement of plants by education, breeding and selection.

The plant-breeder is an explorer into the infinite. He will have "No time to make money," and his castle, the brain, must be clear and alert in throwing aside fossil ideas and rapidly replacing them with living, throbbing thought followed by action. Then, and not till then, shall he create marvels of beauty and value in new expressions of materialized force, for everything of value must be produced by the intelligent application of the forces of nature which are always awaiting our commands.

The vast possibilities of plant-breeding can hardly be estimated. It would not be difficult for one man to breed a new rye, wheat, barley, oats or rice which would produce one grain more to each head or a corn which would produce an extra kernel to each ear, another potato to each plant or an apple, plum, orange or nut to each tree.

What would be the result? In five staples only in the United States alone the inexhaustible forces of Nature would produce annually, without effort and without cost, 5,200,000 extra bushels of corn, 15,000,000 extra bushels of wheat, 20,000,000 extra bushels of oats, 1,500,000 extra bushels of barley, 21,000,000 extra bushels of potatoes.

But these vast possibilities are not alone for one year or for our own time or race, but are beneficent legacies for every man, woman and child who shall ever inhabit the earth. And who can estimate the elevating and refining influence and moral value of flowers with all their graceful forms and bewitching shades and combinations of colors and exquisitely varied perfumes? These silent influences are unconsciously felt even by those who do not appreciate them consciously, and thus with better and still better fruits, nuts, grains and flowers will the earth be transformed, man's thoughts turned from the base, destructive forces into the nobler productive ones which will lift him to higher planes of action toward that happy day when man shall offer his brother man, not bullets and bayonets, but richer grains, better fruits and fairer flowers.

Cultivation and care may help plants to do better work temporarily, but by breeding, plants may be brought into existence which will do better work always in all places and for all time. Plants are to be produced which will perform their appointed work better, quicker and with the utmost precision.

Science sees better grains, nuts, fruits and vegetables, all in new forms, sizes, colors and flavors, with more nutrients and less waste and with every injurious and poisonous quality eliminated and with power to resist sun, wind, rain, frost and destructive fungus and insect pests; fruits without stones, seeds or spines; better fibre, coffee, tea, spice, rubber, oil, paper and timber trees, and sugar, starch, color and perfume plants. Every one of these and 10,000 more, are within the reach of the most ordinary skill in plant-breeding. On the plant-breeder now rests one of the next great world movements, the guidance of the creative forces are in our hands.

Man is slowly learning that he too may guide the same forces which have been through all the ages performing this beneficent work which he sees everywhere above, beneath and around him in the vast teeming animal and plant life of the world.

These lines were penned among the heights of the Sierras, while resting on the original material from which this planet was made. Thousands of ages have passed and it still remains unchanged. In it no fossils or any trace of past organic life are ever found, nor could any exist, for the world creative heat was too intense. Among these dizzy heights of rock, ice-cleft, glacier-plowed and water-worn, we stand face to face with the first and latest pages of world creation, for now we see also tender and beautiful flowers adding grace of form and color to the grizly walls and far away down the slopes stand the giant trees, oldest of all living things, embracing all of human history; but even their lives are but as a watch-tick since the stars first shone on these barren rocks, before the evolutive forces had so

gloriously transfigured the face of our planet home.

LUTHER BURBANK.

PLANTS, Classification of. *Vegetable kingdom.* All the plants in the world are most easily considered in systematic order, especially with reference to their arrangement in branches, classes, orders, etc. On account of the vast numbers of known species of plants (nearly 250,000) it is necessary that they should be arranged in an orderly system, for in this way only can we readily refer to or remember them. Of course, there may be many useful systems of plants, that is, systematic arrangements of the thousands of species, and in fact many systems have been proposed from time to time by different botanists. More than 300 years ago, Cesalpino, in Italy, proposed a system in which the 15 classes which he recognized were separated primarily into "trees" and "herbs," and these were again distinguished by their fruits and seeds. A half century later Morison, in England, devised a system of 18 classes based upon characters of the plant as a whole (trees, shrubs, herbs, etc.), the inflorescence and the fruit. About 200 years ago Ray, in England, published his system of 23 classes, in which he still adhered to the time-honored primary division into "herbs" and "trees," the former of which he divided into the "imperfect" (seaweeds, fungi, mosses, ferns, etc.), and the "perfect" herbs. His "perfect" plants were divided into "dicotyledons" and "monocotyledons," as they are to this day, and several of his classes were practically identical with some of the families of the present time, as Umbelliferae, Leguminosae, grasses, etc. About the same time Bachmann, in Germany, proposed a system in which he rejected the common division into trees, shrubs and herbs, and based his 18 classes upon the form of the flower; first, whether regular, irregular or incomplete, and then, whether monopetalous, dipetalous, tripetalous, etc. At the same time Tournefort, in France, proposed still another system and based his 22 classes on characters derived from the corolla. However, he still adhered to the division into herbs and trees. Linné, in Sweden, a little more than 160 years ago gave the world his so-called sexual system, in which the number and relation of the stamens characterized the 24 classes, which were again divided into orders, mainly upon characters derived from the pistils. This system, while quite artificial, was very useful in enabling botanists to arrange their rapidly increasing knowledge of plants, and it was very generally used for a century.

We owe to Linné also the suggestion of a more natural system, which he published in fragmentary form contemporaneously with his sexual system. He recognized the greater groups Acotyledons, Monocotyledons, Dicotyledons and Polycotyledons, and such smaller ones as the Orchideæ Liliaceæ, Gramina, Coniferæ, Amentaceæ, Compositi, Umbellatæ, Bicornes, Pomaceæ, Drupaceæ, Caryophyllei, Asperifoliæ, Stellatæ, Papilionaceæ, Siliquosæ, Personatæ, Filices, Musci, Algæ, Fungi, etc., which have since been incorporated into most natural systems under these or slightly different names. Half a century later this bore fruit in the system of Jussieu (in France) which divided the vegetable kingdom into Acotyledons, Monocotyledons, and Dicotyledons, and recognized 15 classes and 100 families. The dicotyledons were divided into Apetalæ, Monopetalæ and Polypetalæ, and the higher families were essentially identical with many of those now generally recognized. Thirty years later (1819) DeCandolle modified Jussieu's system, reversing the sequence so as to proceed from the higher to the lower, and dividing the petaliferous dicotyledons into the Thalamiflorals, Calyciflorals and Corolliflorals. He recognized 161 families of plants of all kinds. Over 50 years ago the Candollean system was further modified by Bentham and Hooker, and until recently this has been the commonly accepted system in English and American botanical textbooks.

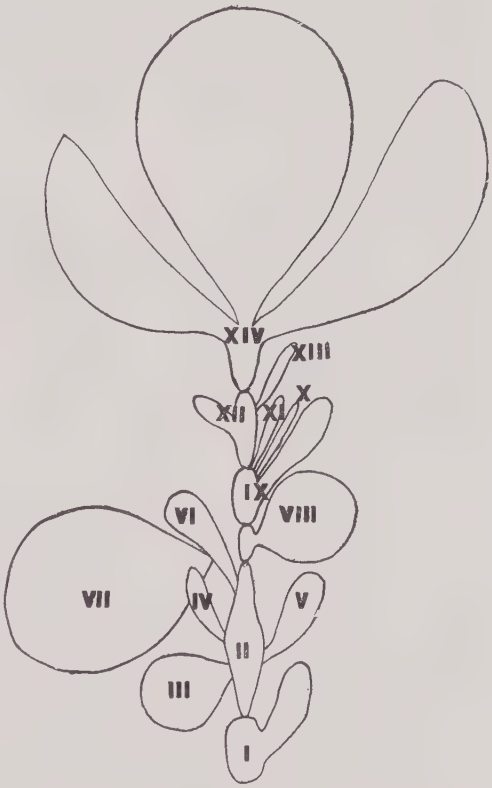

Chart showing the relationship of the phyla of the Vegetable Kingdom, the respective areas being proportional to the present number of species in each phylum.

About 35 years ago Eichler (in Germany) published his system, in which the vegetable kingdom was separated into five "divisions,"—Thallophyta, Bryophyta, Pteridophyta, Gymnospermæ, and Angiospermæ, and under these were about eight classes and nearly 40 orders. This by modification has given rise to the system of Engler (in Germany) now in common use in the United States, which in its latest form recognizes 13 primary "divisions" of the vegetable kingdom, 38 classes, about 100 orders and nearly 600 families.

The system outlined below, while conforming in numerous points with that of Engler,

differs from it in many fundamental as well as minor points. It is an attempt to make the system conform to the author's conception of the course of evolution in the vegetable kingdom. The general relations of the classes to one another may be indicated by the chart on the preceding page.

Phylum I. Myxophyceæ.— The Slime Algæ — Single cells or groups or threads of cells; blue-green to brown-green or in some cases colorless; reproduction typically by fission, rarely by internal cell formation; sexual reproduction lacking; cell walls usually soft; often secreting a gelatinous substance within which the plants remain imbedded. Fresh water and marine, one order hysterophytic and omnipresent. Two classes are recognized.

Class 1. *Archiplastideæ.* Nucleus illy defined; chloroplasts not differentiated; cell walls containing chitin. About 2,000 species.

Order 1. *Chroococcales.* The plants of this order are strictly unicellular or grouped into irregular or regular colonies, but not filamentous; coloring matter present. (Fig. 1). Two families, mostly of fresh water.

Fig. 1.— A cell of Chroococcus in process of fission; much magnified.
Fig. 2.— Part of a filament of Oscillatoria; much magnified.
Fig. 3.— A cell of Protococcus which has divided into three cells, which have not yet separated; much magnified.
Fig. 4.— A young filament of Uronema; much magnified.
Fig. 5.— Parts of two filaments of Spirogyra just before the fusion of the protoplasm of contiguous cells; much magnified.
Fig. 6.— Part of plant of Vaucheria, showing root below and green filament above, with antherid and two oogones; much magnified.
Fig. 7.— A whole plant of Dictyoneuron; much reduced.

Order 2. *Oscillatoriales.* In this order the cells are in threads which mostly do not branch; colored blue-green to brown-green; some species inhabit hot springs. Six families, including such genera as Oscillatoria (Fig. 2), Nostoc, Rivularia, etc.

Order 3. *Bacteriales.* The Bacteria. Usually minute, filamentous, or by the early solution of the filament few or one celled; lacking chlorophyll, hence saprophytic or parasitic on plants or animals, frequently causing diseases; some genera motile by flagella. A large and important group of omnipresent forms of the utmost importance. The larger filamentous forms are certainly closely related to the foregoing order, but there is considerable uncertainty as to the relationship of the more minute, one-celled genera. Seven or more families.

Class 2. *Holoplastideæ.* Nucleus with definite membrane; typical chloroplasts present. Only one order of about 20 species.

Order 4. *Glaucocystales.* Minute, one-celled, fresh water algæ.

Phylum II. Chlorophyceæ.— The Simple Algæ. Single cells, irregular or regular colonies, plates or most often filaments of cells; bright green, or rarely colorless; nucleus with membrane; chloroplasts well developed; cell walls of cellulose or related substance; reproduction by fission or internal development of zoospores or both, and usually also by the union of equal motile gametes or small motile sperm and feebly motile or non-motile egg to form a thick-walled zygote. Chiefly fresh water plants, a few genera, however, almost exclusively marine. Two classes are here recognized.

Class 3. *Protococcoideæ.* The Green Slimes. The plants of this class are strictly unicellular or united into irregular or regular colonies; mainly found in fresh water or moist places. Over 400 species, many world-wide in their distribution. One of the latter, Protococcus (Fig. 3), forms a green, paint-like coating on damp walls, tree trunks, etc. Two orders are recognized.

Order 5. *Tetrasporales.* The plants of this small order are embedded in gelatinous colonies, or provided with gelatinous stalks in some of the genera that do not form colonies. Reproduction is both by division of the cells and by zoospore formation, frequently besides by the union of equal motile gametes. Perhaps four families should be distinguished.

The order *Volvocales* is clearly closely related to the foregoing order, but is distinguished by the fact that the cells retain their flagella and remain motile, even in their vegetative state. On the other hand they present no sharp line of demarcation from the Flagellates among the animals, so that it seems best to exclude this order from the vegetable kingdom, looking upon it as perhaps the bridge between the two kingdoms.

Order 6. *Protococcales.* In this order the plants lack the gelatinous stalks or matrix. Furthermore, with a very few exceptions of rather uncertain relationship, the asexual reproduction takes place only by the internal division of the vegetative cells into motile zoospores or non-motile autospores, the ordinary type of fission of the cells being absent. Those forms with zoospores frequently also possess sexual reproduction by the union of equal or unequal motile gametes. All of the 10 or more families are green except the Synchytriaceæ, which consist of minute parasites in the cells of higher plants.

Class 4. *Confervoideæ.* The Confervas are filamentous (rarely stratose) plants which may be branched or less often simple. The color is usually bright green. Asexual reproduction is mostly by the setting free of motile zoospores, although in some genera these are replaced by autosphores. Sexual reproduction shows all gradations from the union of gametes which are equal and motile to those in which both gametes are motile but unequal and finally to forms where only the small sperm cells are motile while the eggs are large and non-motile within the mother cell (oogone). While a few forms are marine the great majority occur in fresh water. In moist climates many species are terrestrial and some are found on the

leaves of tropical evergreen trees. A few species enter such leaves and pass a partially parasitic existence. Over 600 species distributed unequally among five orders, of which the following are the most important:

Order 7. *Chætophorales.* Unbranched or mostly branched filaments, usually attached; in one family, sheets or tubes of cells; sometimes flat discs; cells normally with one chloroplast with but a single pyrenoid, and with a single nucleus; cell wall usually in one piece; asexual reproduction by various types of zoospores; sexual reproduction by the union of equal or unequal motile gametes. The plants of this order vary considerably in size. The delicate unbranched thread-like Uronema (Fig. 4) is barely one of two millimeters long, while some of the beautiful, much branched species of Draparnaldia exceed 10 centimeters in length. The delicate marine plants known as Sea Lettuce from their resemblance to a leaf of lettuce, are sometimes over a metre long.

Order 8, *Microsporales* and order 9, *Prasialales,* each with but a single family and but few species, are filamentous algæ undoubtedly related to the foregoing order and by some authors included in it.

Order 10, *Oedogoniales* consist entirely of fresh-water filamentous forms, either unbranched or branched. The asexual reproduction is by means of large zoospores produced singly in the vegetative cells of the filament. In their sexual reproduction a higher stage is attained than in any of the groups yet mentioned. In certain specially modified cells are produced one or two small, motile sperms which swim to the large non-motile eggs which are produced singly in special, swollen cells which are provided with an opening to permit the entrance of the sperm. There are approximately 250 species known from all parts of the world, divided into three genera, forming one family.

Order 11. *Coleochætales.* The few species of the single genus of this order are exclusively fresh-water forms and small. They live attached to objects in the water, such as stems of plants, sticks, etc., and form more or less circular discs (Fig. 10) or more rarely low cushions, in which the branched filaments are radially arranged. Many of the cells bear long, bristle-like extensions. Asexual reproduction consists of the formation of motile zoospores, singly in the vegetative cells; sexual reproduction occurs by the union within the usually long-necked oogone of the single large, non-motile egg and a small motile sperm which has been produced singly in a small terminal antherid. The great advance in this order is that after fertilization of the egg the surrounding vegetative cells send out branches that tightly invest the oogone in a protective coat. After a period of rest the fertilized egg divides into eight to 16 cells, each of which develops a single zoospore which produces a new plant.

Phylum III. Zygophyceæ.— The Conjugate Algæ — Aquatic chlorophyll-containing plants forming delicate, unbranched filaments which may be many centimeters long or reduced to but few cells. In many cases they consist of single cells which separate as soon as they divide. A comparative study of the various forms of this variable group makes it seem probable that these latter are to be considered as descended from long filamentous forms which have broken up early so as to be few or one-celled. Asexual reproduction is by fission only, with the doubtful exception of some little known forms. Sexual reproduction is by the fusion of the protoplasmic contents of two contiguous cells, either by means of a tube formed as a result of the contact of the cells, or by the breaking apart of the cell walls so that the two masses of protoplasm lie in contact in the space between the cells. The result of the union is the formation of a thick-walled resting spore (zygospore). Throughout the phylum the cells possess but a single nucleus and one to several, definite chloroplasts, colored either green or brown. The filamentous forms of the two classes form the connecting link as the one-celled species are extreme modifications of the group in different directions.

Class 5. *Conjugatæ.* These are plants with bright green chloroplasts and with cellulose walls. They are confined to fresh water and usually have a slimy coating which makes them slippery to the touch. They may be long filaments or in one order more often reduced to short filaments or separate cells.

Order 12. *Zygnematales.* Pond Scums. These plants are long filaments usually floating in the water, rarely attached, with chloroplasts star, band or disc shaped. The well-known Spirogyra (Fig. 5) with its spirally wound chloroplasts is a favorite subject of microscopic study. About 150 species.

Order 13. *Desmidiales.* Desmids. The beautiful plants belonging to this order are almost all visible only under the microscope. The more primitive forms possess filaments but most of the 2,100 species are one-celled. The cell wall is frequently constricted at the middle and mostly roughened with spines or tubercles. The cell wall typically is in two pieces which meet at the middle of the cell. A few species are motile, being able to glide along, but they lack flagella. Two or three families are recognized.

Class 6. *Bacillarioideæ.* Diatoms. The plants of this class are also microscopic. Their mode of reproduction is much like that of the foregoing class. Like the Desmids their walls are in two distinct halves which either meet at their edges or overlap a little like the cover and base of a pill-box. The walls are heavily impregnated with silica and are in consequence almost indestructible, so that they persist for hundreds of thousands of years as fossils, the well-known and valuable «diatomaceous earth.» The chlorophlasts are disc shaped or elongated, and brown in color. These plants are found in fresh and salt water from the Arctic and Antarctic zones to the Equator. The more than 5,000 species are distributed in two orders of six to eight families each.

Order 14. *Eupodiscales.* Round Diatoms. Mostly marine, cells round or polygonal in end view of the filament.

Order 15. *Naviculales.* Flat Diatoms. Fresh water and marine; filament flattened so that in end view it is elliptical or boat-shaped.

Phylum IV. Siphonophyceæ.— The Tube Algæ. In all of the plants mentioned hitherto the cells, with rare exceptions, were provided with but a single nucleus. In this phylum, however, we find the type of cell structure known as a coenocyte, a sort of compound cell that has many nuclei embedded in the cytoplasm instead of the one. Furthermore, the growth of the

plants of this group, which are almost all filamentous, or modifications of filaments, is mostly terminal, instead of occurring at all points in the filament as was the case in the preceding phyla. Aside from these points of difference the phylum shows many points of similarity to the Chlorophyceæ from which it doubtless arose. The plants are rather coarse, more or less branched filaments, bright green in color (rarely red in a few forms) or colorless in the species that lack chlorophyll. The colored forms are aquatic and for the most part marine; the colorless forms are fresh-water or terrestrial. Asexual reproduction is by means of motile zoospores or in some of the colorless species by the formation of wind-borne cells that are not motile. Sexual reproduction is by the union of equal or unequal motile gametes, or of motile sperms and nonmotile eggs, or by the direct union of protoplasm of sperm and egg through a connecting tube, the result in any case being a more or less thick-walled resting spore. About 1,200 species, probably best disposed in three classes. It is possible that some of the plants included in this phylum are descended from some of the class Protococcoideæ and others from the class confervoideæ, but that is a disputed point.

Class 7. *Siphonocladeæ.* Plants consisting of microscopic or moderate sized bladders from which may sprout smaller bladders or short filaments, or, of coarse filaments constricted or segmented at intervals to form numerous coenocytes. The filamentous forms are mostly branched, either irregularly or in definite patterns, often with the branches whorled; chloroplasts small disks or more often large and net-like; about 425 species, marine in most cases; a few families also contain fresh-water species. Reproduction asexually usually by zoospores, sexually (where known) by the union of equal, motile gametes, or of non-motile egg with motile sperm, to form a zygote which may germinate immediately or function as a resting spore.

Order 16. *Siphonocladales* is the only order in this class. In fresh water may be frequently found the filamentous Water Flannels (Cladophora); on damp, clayey soil often appear the minute bladder-like, green plants of Botrydium. In the ocean, particularly in the warmer waters, are found large numbers of plants of this order, among them the Mermaid's Wineglasses (Acetabulum) with calcified slender stem bearing at its apex a whorl of united, spore-bearing segments, forming a structure resembling some of the more delicate mushrooms. Four or five families are recognized.

Order 17. *Charales.* Stoneworts. (Fig. 24). The relationship of this group is obscure. It seems likely that it should be placed in the vicinity of those members of Class Siphonocladales which possess whorled branches. The plants of this group are inhabitants of fresh water, chiefly shallow lakes and ponds, and are frequently incrusted with lime. They consist of long septate tubes with whorls of branches at the joints, these in turn often with similar whorls of branches; the ultimate branches are the so-called leaves, which are cylindrical, pointed coenocytes. Asexual reproduction does not occur except by the formation of buds or of bulb-like structures. Sexual reproduction by the union of a minute motile sperm with the single large, non-motile egg contained within the oogone which is surrounded by a tight protective layer of spirally wound threads. Over 200 species, divided into six genera, in two families. Chara and Nitella are the genera most frequently found.

Class 8. *Siphoneæ.* Tube Algæ. These plants consist of elongated tubes, branched irregularly or so as to produce definite structures; these tubes are coarse and not septate, except for the production of the zoospores by which asexual reproduction mostly takes place, or of the gametes, which are (where known) always unequal, both sexes being motile in some cases or the female gamete (egg) non-motile and retained within the oogone. The plants are typically green, with numerous disc-shaped chloroplasts. In a few marine forms a violet color conceals the green to some extent. Probably two orders should be recognized.

Order 18. *Bryopsidales.* Marine forms of moderate size or sometimes large; irregularly branching coarse, non-septate, coenocytic threads or tangled masses of such threads forming definite structures, in one family the large coenocyte differentiated into parts functioning as roots, stems and leaves; asexual reproduction where known by formation of zoospores in lateral zoosporangia or by the breaking up of the plant; sexual reproduction where known by the union of unequal motile gametes; confined mostly to warmer waters. The genus Codium contains representatives forming rope-like masses sometimes several feet long; Caulerpa forms a creeping, branched stem, rooted at intervals and sometimes several feet long with upright, sometimes leaf-like branches several centimeters high. Its only mode of reproduction, so far as known, is the death of the older connecting stems so that the plant becomes separated into independent individuals. About four families, exclusively marine.

Order 19. *Vaucheriales.* Green Felts. The plants of this order are coarse, branching, green tubes, mostly forming dense tangled felts. They are confined to fresh water or to wet earth, except the few species of one family which, although green, are parasitic. Asexual reproduction by large zoospores formed in segments at the ends of the filaments, rarely by non-motile spores (aplanospores) formed within the filament. Sexual reproduction (wanting in the parasitic forms) by the union of motile sperm and nonmotile egg within the oogone. Two families. Here we find the common Green Felt (Vaucheria — Fig. 6, common in springs, damp ground, slow-moving streams, etc., as well as the peculiar leaf parasite of Aroids (Phyllosiphon).

Class 9. *Phycomyceteæ.* Tube Fungi or Lower Fungi. These plants are undoubtedly derived from the order Vaucheriales, but differ in several particulars. They lack chlorophyll and hence are either parasitic in their mode of life or feed on dead organic substances. They consist of long, usually irregularly branched, nonseptate tubes (sometimes septate in old age) which may be all alike or which may show distinction of vegetative portion contained within the substratum upon which the plant is feeding and a usually coarser external reproductive part. Asexual reproduction varies from the formation of zoospores in terminal zoosporangia, which remain attached, to the production, on the one hand, of separable zoosporangia (conidia)

which produce zoospores only when they fall into water and in some genera fail to produce zoospores at all, and on the other hand, of aerial sporangia within which are produced nonmotile, walled spores which are set free by the rupture of the sporangium. Sexual reproduction in the more primitive forms is close to that in Vaucheria, consisting of the union of motile sperm with non-motile egg within the oogone; a more advanced step is the use of a conjugation tube to transfer the sperm nucleus to the oogone; the most advanced case being the reduction of the differences between the male and female reproductive organs until they are almost equal and similar (as in some sorts of Mucor). The plants of this class are aquatic, or parasitic within land plants, or saprophytic and terrestrial. They are mostly easily visible to the naked eye. About 400 species, distributed in four orders.

Order 20. *Saprolegniales.* Water Molds. These are aquatic fungi with zoospores produced in permanently attached zoosporangia. Some of them are troublesome parasites on young fish in fish hatcheries, especially species of Saprolegnia and Achlya, others are serious pests of seed beds (Pythium). About six families.

Order 21. *Peronosporales.* Downy Mildews. These are parasites of higher plants within which they live, sending out their reproductive branches to produce their conidia which in most cases produce zoospores when they fall into water. The fungi causing respectively Late Blight of potato (Phytophthora), Downy Mildew of grape (Rhysotheca), White Rust of cabbage and radish (Albugo), are among the most common. Two families are recognized.

Order 22. *Mucorales.* Terrestrial; spores usually produced in aerial sporangia; but little difference between male and female structures in sexual reproduction. Saprophytic; sometimes parasitic on other fungi. Four families of interesting fungi including the ubiquitous Black Mold of bread (Mucor).

Order 23. *Entomophthorales.* Insect Fungi. These are minute fungi mostly parasitic within the bodies of insects which they kill. The asexual spores are produced singly on short branches which emerge from the body of the insect. The male and female reproductive organs are scarcely distinguishable. Here belongs the Fly Fungus which kills flies in large numbers in the early autumn (Entomophthora).

Phylum V. Phæophyceæ.— Brown Algæ. This group is composed of filamentous or, more commonly, massive plants, the latter of considerable dimensions and often differentiated into roots, stems and leaves. They are of a brownish-green color, due to the presence of a brown pigment which hides the bright green of the chlorophyll. The cells are uninucleate and the chloroplasts are small and disc-like or larger and net-formed. With a very few exceptions the members of this phylum are exclusively marine. The thousand or so species are divided into three classes.

Class 10. *Phæosporeæ.* The Kelps. These range from small filamentous branching plants to enormous plants hundreds of feet in length with stems, roots and leaves. Asexual reproduction occurs throughout the class by the formation of zoospores which are biflagellate and pear or kidney shaped. The organs in which they are produced, the zoosporangia, are often collected in patches on the surface of the plant. (Fig. 7). Sexual reproduction is known in many of the forms and consists of the union of equal or unequal motile gametes which are very similar to and sometimes indistinguishable from the zoospores. In a few forms the eggs appear to lack power of motion. The approximately 500 species of this class are largely found in the cooler parts of the ocean. They may be divided into three orders as follows:

Order 24. *Ectocarpales.* Gametes all motile and equal or nearly so, or the egg non-motile; from filamentous to massive forms. Perhaps 16 families should be recognized. Among the common plants of this order are the Devil's Aprons (Laminaria) which consist of a stout stem with roots below and terminating above in a broad, often longitudinally split, leathery leaf, the whole sometimes attaining a length of one to several yards and a width of a foot. The Giant Kelp (Macrocystis) of the Pacific Ocean is no doubt the longest plant in the world, sometimes reaching the enormous length of 700 feet. It consists of a long, tough, round stalk, an inch or more in diameter and many feet in length with large branching roots below and bearing many narrow leaves, two to four feet long, each having a large air vessel (an inch in diameter and four or five inches long) in its petiole. By means of these air vessels the leafy portion of the plant floats out at the surface of the water. Nor are the Sea Trees (Lessonia) also of the Pacific Ocean, any less interesting. They consist of erect stems, rooted below and branched above, the latter bearing many pendent narrow leaves. Some of these veritable trees are several yards in height. The pretty Mermaid's Strings (Chorda) are flexible, string-like stems, a yard or so in length, rooted below and smooth and delicately fringed above. They occur in the Atlantic and Pacific oceans. Dictyoneuron (Fig. 7) of the Pacific Coast of North America is a foot or so long.

Order 25. *Cutleriales.* The plants of this order are small to several inches tall, disc-shaped or erect and more or less flattened and sometimes much divided, frequently in a dichotomous manner. Asexual reproduction is by means of zoospores which are produced in different plants from those producing the gametes. The gametes are motile, but differ exceedingly in size for the two sexes. Usually the fertilized egg produces a zoospore-bearing plant and vice versa, but this is not always the case.

Order 26. *Tilopteridales.* Filamentous plants with typical zoospores and with small, motile sperms and large, non-motile eggs which are produced singly in the oogones and set free before fertilization. Only a few species of little importance and infrequent in occurrence.

Class 11. *Dictyotineæ.* The few species (about 130) included in this class in its single order.

Order 27. *Dictyotales,* are wholly marine, mainly in those portions of the sea where the water is fairly warm. They are of moderate size, growing fast to rocks or other objects, as in the preceding class. They are differentiated into basal holdfast or root and vegetative shoot

which is usually more or less flattened. It consists of several layers of cells, but there is little tissue differentiation. Sexual reproduction is by means of non-motile eggs, set free singly from superficial, crowded oogones and fertilized by minute, motile sperms produced in large numbers in similarly clustered, superficial antherids. These fertilized eggs give rise to similar plants, which, however, do not bear sexual organs, but reproduce by the production, in fours, of naked "tetraspores" which in their turn produce the sexual plants. Dictyota (Fig. 8) is the principal genus.

8 9 10

FIG. 8.— A plant of Dictyota; somewhat reduced.
FIG. 9.— Portion of a plant of Sargassum; much reduced.
FIG. 10.— A plant of Coleochæte; much magnified.

Class 12. *Cyclosporeæ.* Rockweeds. These are branching, medium sized plants, growing at or near the surface of the water, often attached to rocks between low and high water. They are exclusively marine and are found from the cold waters of the north and south Atlantic and north and south Pacific to the warm waters of the tropics. They are firmly rooted below and in some cases the plant body is differentiated into stem and leaves. No means of asexual reproduction are known. The sexual organs are formed in narrow-mouthed, almost spherical depressions (conceptacles) on the surface of the unmodified vegetative branches or of specially modified reproductive branches. The eggs are produced by eights, fours, or even singly in the oogones, escaping through the mouth of the conceptacle and there meeting the small motile sperms which have been produced in large numbers in the numerous small antherids in other conceptacles, either on the same or on another plant. The fertilized egg germinates almost immediately. There are upward of 400 species, all included in one order,

Order 28, *Fucales,* and divided among four families. The largest genus is Sargassum (Fig. 9) with about 200 species, of the warmer waters of the sea, one of which (*S. bacciferum*) is the "Gulf-weed" which floats in large quantities in the so-called "Sargasso Sea" in the mid-Atlantic Ocean. Originally, attached by its roots it has broken loose and been carried away by the Gulf Stream and other ocean currents. It floats in the water by means of its many little air bladders which occur on the petioles. Other common plants of this class are the Rockweeds, proper (Fucus), which are attached to rocks and wharves between high and low-tide marks and the Knotty Rockweed (Ascophyllum) with large bladders in its slender stems.

Phylum VI. RHODOPHYCEÆ.— The Red Seaweeds. These plants are minute to middle-sized or even large (a foot or more in length), rooted below and more or less branched above. In the simpler forms they are unbranched or branched filaments, but many form broad sheets or large and massive plant bodies. All but a few species are chlorophyll-bearing, but the green color is concealed by a red or purple pigment. The species are with very few exceptions marine. A very few species are true parasites in other seaweeds. Asexual reproduction is by means of naked, non-flagellate cells set free singly or in fours. Sexual reproduction is by the union of the nucleus from a naked, non-motile sperm with that of an egg enclosed within the oogone, the resulting cell dividing into few or many cells, some or all of which are the carpospores which give rise to the new plants. The phylum is divided into two unequal classes.

Class 13. *Bangioideæ.* Simple or branching filaments or sheets of cells. Asexual reproduction by the formation of single naked cells (monospores). Sexual reproduction by the transformation of ordinary vegetative cells into oogones or antherids. After fertilization, the oogones divide into four or eight cells (rarely not dividing) which slip out of their walls as naked, non-flagellate, amœboid carpospores. About 50 species, doubtfully divided into two orders.

Order 29. *Bangiales.* Chloraplasts single in each cell. Bangia with a dozen or more species of filamentous plants and Porphyra, "Laver," of almost 20 species are the principal genera. The last-named are flat, leaf-like, purple plants, which are very common throughout the world in salt or brackish water and are used for human food. One family only; marine.

Order 30. *Rhodochætales.* Chloroplasts several to many in each cell. Filamentous, sometimes corticated plants. Asexual reproduction by monospores; sexual reproduction not known. Two families, one marine and one fresh water. A doubtful group because of ignorance as to the sexual reproduction.

Class 14. *Florideæ.* True Red Seaweeds. This class includes approximately 3,000 species of plants, found in the seas of all parts of the world and in small numbers in fresh water as well. A few species are true parasites upon other seaweeds, and entirely colorless; others although parasitic in habit still retain some of their color. The great majority, however, are not at all parasitic. Many are edible and some are of great economic value. In this class the cells possess mostly numerous, small, disc-shaped chloroplasts and are connected to one another by plasmatic strands through the central openings in the cell wells, both being features lacking in the preceding class. Asexual reproduction is by means of monospores in a few cases, where there is no alternation of sexual and non-sexual plants. In the contrary case, however, which is the rule in nearly all species, the asexual reproductive cells are produced in fours (*tetraspores*) on one generation of plant, these producing the plants that bear the sexual organs. The latter are special cells, not merely slightly modified vegetative cells. The oogone has a long neck (*trichogyne*) and is the terminal cell of a row of three or four cells. After fertilization by the water-borne, non-motile, naked sperm the oogone sends out branches at the ends of which are produced the

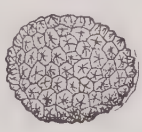
carpospores, or the oogone fuses with adjacent cells and from the common cell thus produced arise the carpospore threads. The carpospores produce the tetraspores plants in the species with alternation of generation.

Order 31. *Nemalionales.* The fertilized oogone grows out directly to form the carpospore-bearing threads. Many of the plants of this group occur in fresh water, e.g., Thorea (Fig. 11) which occurs as a somewhat slimy, branched, brown string, several inches long in fresh-water streams. Nemalion forms a mass of slimy, brownish threads on rocks between high and low water marks in the sea. Many species of this order show no alternation of generations and hence produce monospores instead of tetraspores.

11

12

13



14

FIG. 11.— Portion of a plant of Thorea; somewhat reduced.
FIG. 12.— A plant of Chondrus; somewhat reduced.
FIG. 13.— A fruit of Microsphæra with its branched appendages; much magnified.
FIG. 14.— A fruit of Tuber; somewhat reduced.

Order 32. *Cryptonemiales.* The fertilized oogone sends out long threads which unite with large nutritive cells in various parts of the plant and there give rise to the carpospore-bearing threads. Asexual reproduction by tetraspores. Worthy of notice is the genus Corallina, in which the plant body is very thoroughly infiltrated and encrusted with lime. The plants are jointed, being flexible at the joints which are not encrusted. The color is a delicate pink.

Order 33. *Ceramiales.* The fertilized oogone fuses with an adjacent nutritive cell, from which then the short sporogenous threads arise, the whole being mostly surrounded with a protective coat of sterile threads with an opening to permit the escape of the carpospores. Asexual reproduction is by means of tetraspores. Some of the plants of this order are filamentous, such as the very common and beautiful Ceramium species, others are more or less leaf-like, as Delesseria.

Order 34. *Gigartinales.* The fertilized oogone fuses with an adjacent nutritive cell as in the foregoing order but the filaments sent out from the latter are long and grow and branch in among the vegetative tissues of the plant. Tetraspores are formed. The plants are not filamentous but many cells thick. *Chondrus crispus,* Irish Moss (Fig. 12), forms branching, purple plants a few inches high in the waters of the North Atlantic. It is used for making blanc mange.

Order 35. *Rhodymeniales.* The nutritive cell with which the fertilized oogone fuses is not formed until after fertilization has taken place. From it grow out short sporogenous threads. Tetraspores are present in all species. Agar-agar, which is of such great importance in bacteriological work, is obtained from an East Indian species of Gracilaria, belonging to this order.

Phylum VII. CARPOMYCETEÆ.—The Higher Fungi. Terrestrial, rarely aquatic, filamentous, branching plants with frequent cross walls, and usually, at first, but one nucleus to a cell. No chlorophyll is produced so that the plants are dependent upon organic matter produced by other organisms. Large numbers are saprophytes, i.e., they feed upon the bodies of dead organisms, or on non-living organic matter, but a vast number are parasites, some of them very destructive, upon animals or plants. Asexual reproduction is present in almost all groups and consists usually of the rounding off and setting free of terminal cells (conidia) of ordinary or special branches. These conidia offer a multiplicity of forms and colors and great variety of detail as to the location on the conidiophores and as to the shape and grouping of the latter. Sexual reproduction is known in all of the larger groups and likewise shows great variability as to detail. In common to all the groups and to the Red Seaweeds from which this phylum probably arose is the fact that the union of sexual cells or nuclei leads to the production of a mass of threads of which the terminal (or subterminal) cells produce the spores which develop into the new plants. The approximately 64,000 plants of this phylum are distributed among three classes.

Class 15. *Ascomyceteæ.* The Sac Fungi are in many respects more primitive than the other classes of the phylum. Their distinguishing feature is the production of the spores in sexual reproduction within terminal or sub-terminal, usually enlarged cells, called asci. In each ascus the number of spores produced is most often eight, although in some cases the number is higher or lower. By bursting of the ascus, the cells are ejected with more or less violence and on germination give rise to the new plants. In some of the families of this class that show the most points in common with the Red Seaweeds sexual reproduction results from the union of a non-motile, water-borne sperm with the elongated portion (*trichogyne*) of the oogone, exactly as in the Class Florideæ. As a consequence of this union there arise from the oogone numerous threads, corresponding to those producing the carpospores, the subterminal cells of which become the asci. In more plants of this class separate sperms are not produced but the antherid comes into direct union with the oogone or its extension, the asci developing, however, in the same manner. In some cases even the antherids seem to have disappeared, and the two sexual nuclei which unite both originate within the oogone. In a few very much simplified forms the oogone is also lacking and asci arise from vegetative cells, the two nuclei that develop within the ascus fusing before the spores begin to be formed. Throughout most of the group the ascus-producing threads are associated with sterile threads so as to form a small or large fruit which may be solid (Fig. 14) or hollow, with or without (Fig. 13) a definite opening, or may open out as a cup or saucer-shaped structure (Fig. 16). In the simplified forms the asci may be naked and

scattered. The class contains about 29,000 species in perhaps 15 orders.

Order 36. *Laboulbeniales.* Beetle Fungi. These are minute fungi of but few cells each, parasitic in the chitinous wall of the body or appendages of beetles and other insects, particularly those of damp places. The oogone is provided with a trichogyne to which the usually naked non-motile sperms become attached. From the cell below the oogone an envelope is produced before fertilization, that completely invests it as a protective coat. The fertilized oogone gives rise to a considerable number of four, rarely eight-spored asci. Over 50 genera and more than 600 species have been recognized from all parts of the world.

Order 37. *Lecanorales.* Disc. Lichens. Fungi parasitic upon lower green and blue algæ, usually forming characteristic, variously colored, flat or erect, leaf-like or leafy stemmed structures growing on the ground, on rocks, on trunks of trees, etc. Sexual reproduction by the union of a minute, non-motile sperm with the many celled trichogyne that grows out from the oogone. The resulting threads that grow out from the oogone bear their asci in a saucer or cup-shaped structure (apothecium). Several thousand species distributed among nearly 30 families. Among them are the Reindeer Moss (Cladonia), which is the most important food for the reindeer, Old Man's Beard (Usnea) which hangs in long streamers from the branches of trees, etc.

Order 38. *Pezizales.* Cup Fungi. In this group the plants are parasites upon other plants than lower algæ or saprophytes. The asci are produced as in the preceding order in cup or saucer-shaped apothecia. In most forms, the details of sexual reproduction are unknown. In a few forms the oogone possesses a long or short trichogyne which grows over to an antherid with which its tip fuses. Antherids are sometimes lacking. Plant consisting of slender, branched, septate threads, usually inconspicuous but apothecia often showy (Fig. 16) varying in size from under a millimeter to 15 to 20 centimeters in diameter. About 10 families. The genus Sclerotinia contains several very destructive plant parasites.

Order 39. *Helvellales.* Related to the foregoing, but the apothecia more or less everted and frequently stalked. The Sponge Mushroom (Morchella) is a very delicious mushroom found in the woods in the spring. Three families.

Order 40. *Caliciales,* and Order 41, *Phacidiales,* are related to the first two orders. The former consist mostly of lichens (i.e., fungi parasitis upon lower algæ).

Order 42. *Tuberales.* Truffles. Plants subterranean, both as to vegetative and reproductive parts. The latter are up to an inch or two in diameter, more or less spherical, and apparently to be looked upon as an apothecium that is highly contorted, with but a very small opening. The common truffle (Tuber, Fig. 14) is found in oak forests in Europe. Some species occur in America.

Order 43. *Exoascales.* Fungi saprophytic or parasitic upon higher plants, with abundant or scanty, branching plant body upon which is produced a single layer of closely placed asci, forming a sort of simplified apothecium. Sexual reproduction unknown beyond the union of two nuclei in the very young asci. Two families of about 60 or more species. Species of the genus Exoascus cause several serious diseases, e.g., the destructive Leaf Curl of the peach and witches' broom of cherry, etc.

Order 44. *Hysteriales.* Slit Fungi. Wood and leaf-inhabiting fungi, as well as "lichens." The apothecium is very much elongated so that its opening forms a slit. Among the "lichens" is Rocella from which the pigment litmus is obtained. The genus Hysterographium (Fig. 15) is common on twigs of ash and other trees. Perhaps seven families.

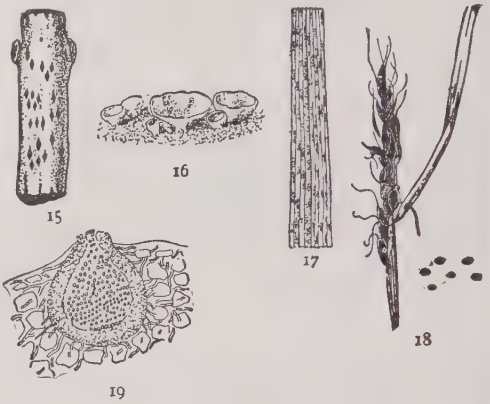


FIG. 15.— A dead stick with black fruits of Hysterographium; slightly reduced.
FIG. 16.— Several fruits of Peziza; slightly reduced.
FIG. 17.— Part of a grass leaf with a Rust (Puccinia) upon it; slightly reduced.
FIG. 18.— Head of wheat affected with a Smut (Ustilago); somewhat reduced.
FIG. 19.— A verticle section through the fruit of Phyllosticta; much magnified.

Order 45. *Pyrenulales.* Closed Lichens. Parasitic on lower algæ. Asci produced in a more or less spherical hollow body (perithecium) with a small apical opening. Twelve or so families of usually small lichens.

Order 46. *Sphæriales.* Black Fungi. Saprophytes or parasites, but not parasitic on algæ (i.e., not "lichens"). Closely related to the foregoing order, possibly to be united with it. Asci produced in more or less spherical hollow bodies (perithecia) with small apical openings (ostioles). Perithecia black and rather brittle; separate, or crowded together, or united by a special fungal mass (*stroma*). Sexual reproduction studied only in a few forms. Oogones provided with trichogyne in some genera, without it in others; separate, non-motile sperms apparently produced in some forms, the oogone and antherid uniting directly in others. More than 6,000 species in 18 or more families. The species of this group are largely found on wood or on living or dead herbaceous stems or leaves. Many of the more important plant diseases are due to their activities; e. g., Black rot of grape due to Guignardia, Scab of apple and pear caused by different species of Venturia, Bitter Rot of apple and many other plants caused by Glomerella, and Chestnut Blight caused by Endothia.

Order 47. *Dothideales.* This order is closely related to the foregoing one from which it differs in that the asci are borne within cavities

in a stroma without a special perithecial wall of their own. The nearly 800 species, representing 140 genera and four families, are found in most parts of the world but are especially abundant in the Tropics. They are, practically without exception, parasites in herbaceous stems and in leaves. The Elm Leafspot which causes the premature falling of elm leaves in Europe is caused by a species of Systremma. More than 300 species of Phyllachora are known, among them the common *Phyllachora graminis* on various grasses.

Order 48. *Hypocreales.* The several hundred species of this order show great similarity to the two foregoing orders, differing principally in the rather bright color and fleshy or leathery consistency of the perithecium or stroma. Many are saprophytes but a number of dangerous parasites occur on plants, e.g., Nectria, causing cankers on limbs of apple; Spermœdia (Claviceps) causing Ergot of rye and other grasses.

Order 49. *Perisporiales.* Mildews. Superficial fungi, mostly parasitic. Asci arising from the base in small closed perithecia, following direct union of antherid with oogone which possesses no trichogyne. Two, possibly three, families of which one (*Erysiphaceæ*) contains many important plant parasites, e.g., Microsphæra (Fig. 13) the cause of the Powdery Mildew of lilac; Sphærotheca, which, when introduced from America into Europe, proved so destructive to the gooseberry; Uncinula, which had a similar history with regard to the European grape.

Order 50. *Aspergillales.* Molds. The many hundred fungi making up this order are very largely saprophytes although a number are parasites of economic value. None are parasitic on algæ. They are mostly well provided with means for asexual reproduction, sometimes the sexual type being produced only rarely. The asci are produced within more or less spherical, closed, solid bodies, being scattered through the mass of the tissue (not basal in a cavity as in the Perisporiales). In a number of cases the union of antherid with the oogone has been observed. The fruits are mostly minute but in two families are large and subterranean. The common Blue Mold (*Penicillium*) is found in damp climates as a destructive mold on shoes and other leather goods; other species are essential to the production of Roquefort cheese; some are parasitic within the ear of man. Thielavia causes a serious root disease of tobacco and other plants.

Order 51. *Saccharomycetales.* These plants show the greatest degree of simplification in this phylum. The plant body may consist of elongated branching threads, or, in many cases, the cells may separate soon after cell division so that one-celled forms result. Even the filamentous forms resolve themselves into the other type under special external conditions. The asci are not formed within any special structure but arise on the filamentous forms as scattered lateral outgrowths, either without, or as a result of, the union of almost similar antherid and oogone. The one-celled forms (yeasts) may become converted directly into asci, with or without previous union of two cells. The most important family of this order is that of the Yeasts, of which the genus Saccharomyces is most important. The common yeasts have been cultivated from time immemorial for the leavening of bread and also for the production of alcoholic beverages.

Class 16. *Teliosporeæ.* Brand Fungi. Long, branching, septate fungi, parasitic within the tissues of higher plants, which are often very seriously injured by them. Asexual reproduction by various types of non-septate conidia. Sexual reproduction consisting of the union of adjacent cells to form binucleate cells. The uniting cells may be definitely located or the union may consist in the division of the nucleus of a cell and the failure of the cytoplasm to divide. The process may occur at various points of development, depending upon the form. The binucleate cells by division give rise to filaments of similar cells. Eventually thick-walled binucleate spores (*teliospores*) are formed in various ways, the two nuclei fusing when the spore is still young. After a short or long resting period, or immediately, in some cases, this teliospore gives rise to a short filament (*promycelium*) upon which are produced four (sometimes more) uninucleate spores (*sporidia*) which serve to infect the new host plant. Over 4,000 species divided among two orders.

Order 52. *Uredinales.* Rusts. The fungi composing this order are among the worst plant parasites of cultivated crops, as well as of innumerable wild plants. Typically, there are five spore forms: (1) teliospores, giving rise to a four-celled promycelium bearing on each cell a (2) sporidium. This produces a fungal growth within a suitable host plant which produces the (3) pycniospores, which appear to be functionless sperms, and the (4) æciospores. There is a sexual union of adjacent threads before this process so that these spores are binucleate. They give rise, in the proper host plant, to a septate branched thread with binucleate cells. From this arise the (5) urediniospores, also binucleate, and later the (1) teliospores. The urediniospores produce a growth exactly like that from the æciospores. They are properly called repeating spores because they do not introduce a different generation. Complications are very numerous, in that many rusts have this latter stage on one kind of host plant and the stage that produces the pycniospores and æciospores on another host. Again, some rusts have no urediniospores and in still others the æciospores also are not produced. The teliospores vary greatly in appearance. Among the better known rusts are the Black Rust of small grains, which has its pycnial-æcial stage upon the common and purple barberry, and its other stages on the small grains and various other grasses (Fig. 17); White Pine Blister rust with its destructive pycnial-æcial stage on the white pine and the other stage on currants and gooseberries; Apple rust, with its destructive pycnial-æcial stage on apple and the telial (there is no uredinial stage) stage on red cedar. Probably 3,000 or more species in three or four families.

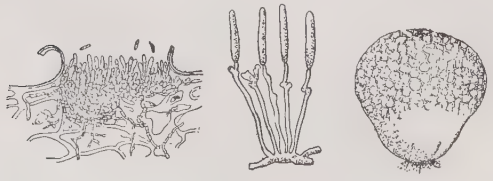
Order 53. *Ustilaginales.* The Smuts. These are also widespread as destructive parasites of cultivated and wild plants. The teliospores are usually produced as a powdery mass, within the tissues of the host plant, often totally destroying portions of the plant and thus being set free as a dark-colored dust. There is not

the complicated life history that the previous order possesses. The promycelium from the teliospores produces sporidia which may infect the host at once or which may give rise to a saprophytic growth on decaying organic matter in the soil, producing numerous small conidia which are capable of infecting the host plants. The young teliospores are binucleate, as are the cells from which they arise, but there is no strict alternation of generations with uninucleate and binucleate cells as in the Rusts. The 1,000 or more species are divided into two families. Among the more destructive parasites are the Loose Smut of wheat (Fig. 18) and the smuts of oats and corn, caused by species of Ustilago, Stinking Smut of wheat caused by Tilletia and several others on rye, barley, sorghum, etc.

Class 17. *Basidiomyceteæ.* In this vast class of about 14,000 species and perhaps nine orders, sexual reproduction has reached almost its lowest ebb. There seems to be no definite union of antherid and oogone at any definite point. By the failure to produce a cross wall, a dividing cell becomes binucleate and thus initiates a series of binucleate cells. Eventually the terminal cells of such threads enlarge, the nuclei fuse and a basidium results. From this bud out four (in some cases more or less) basidiospores, which start the new plants. The basidia are produced on surfaces either within a closed fruit or exposed to the air; in the former case the fruit opens in some way (sometimes only by decaying) to permit the spores to escape, in the latter they are set free directly into the air. The fruits are mostly of good size, from a few millimeters up to a foot or more in diameter.

Order 54. *Hymenogastrales,* and Order 55, *Sclerodermatales,* consist of fungi growing in the soil and producing their moderate-sized fruits below the surface, although they may emerge at maturity. The basidia are produced within the fruits. Unimportant groups.

Order 56. *Lycoperdales.* Puff Balls. The large, fleshy fruits of this order are often subterranean at first. They are fleshy to begin with and edible. After the spores have been produced in the small, sinuate cavities, the tissues all disintegrate, leaving the dry dark-colored spores in a large central cavity, usually with an apical pore. On logs and on the ground are found numerous species of Lycoperdon (Fig. 22), the Giant Puff Ball (Calvatia), found on lawns and meadows, sometimes reaches a diameter of 18 inches or more. The little Earth Stars (Geaster) also belong here, being puff balls whose outer coat splits down longitudinally, turning out so as to form a star-like figure.



20 21 22

FIG. 20.— A vertical section through the fruit of Gloeosporium; much magnified.

FIG. 21.— Several spore-bearing threads of Ramularia; much magnified.

FIG. 22.— A fruit of a Puff Ball (Lycoperdon); somewhat reduced.

Order 57. *Nidulariales.* Bird's Nest Fungi, whose dainty little cup or beaker-shaped fruits, containing a number of egg-like bodies, are found on the ground or old sticks, are few in number as to species, but widespread as to distribution.

Order 58. *Phallales.* Stink Horn Fungi. The fruits of the usually terrestrial fungi of this order are fleshy and produce their spores internally as in the foregoing orders. Their escape is furthered by the rupture of the fruit and the deliquescence of the sporogenous tissue into a foul-smelling slime which attracts the carrion-loving flies which serve to distribute the spores. The common Stinkhorn (Phallus) is found the world over.

Order 59. *Agaricales.* In this order which contains most of the commoner fungi of this class, the fruit is from medium size to large. The basidiospores are produced on basidia which line surfaces exposed to the outer air so that as the spores fall they are carried off by the wind and do not have to await some process by which an opening is made, as in the foregoing orders. The order has about five families, all of them world-wide in their distribution. Best known are the toadstools, in which the basidium layer occupies the surfaces of the radiating gills. These umbrella-shaped fruits (Fig. 23) are familiar to everyone. Of

23 24 25

FIG. 23.— A fruit of a Toadstool (Amanita); somewhat reduced.

FIG. 24.— A plant of a Stonewort (Chara); considerably reduced.

FIG. 25.— A Liverwort (Grimaldia) of the thallose type; somewhat reduced.

the 6,000 or more species of toadstools a few are deadly poisonous, more are mildly so, and the vast majority are harmless. One species (*Agaricus campestris*) is cultivated the world over in temperate climates. Numerous other species are collected regularly as they appear in the wild state. Most toadstools grow on decaying vegetable matter in the soil, but some are wood destroyers; a few even attacking living trees. The Pore fungi, on the other hand, are mostly wood inhabitants, causing the decay of the heart wood in some cases; of the sap wood in others or of both. They may attack only dead trees or may grow only on living trees. They contain some of our most dangerous timber destroyers. Mostly their fruits are bracket or hoof-shaped, growing out from the side of the tree or timber, within which the richly branched, septate threads of the fungus are spreading. On the under side of this fruit are minute pores which, like the gills of the toadstools, are lined with the

basidia. Among the more widely distributed fungi of this family are various species of Fomes and Polyporus. In another family of the order, the basidia line teeth or prickles that hang from the under side of the fruit (Hydnum) while in still other families the smooth surface of the fruit bears the layer of basidia (Corticium). Most of the members of these latter families are also wood destroyers, but few are found on any but already decaying logs, sticks, etc. One species of Corticium, however, is a destructive root parasite of potato, beet and many other cultivated crops.

Order 60. *Exobasidiales.* The basidia in this order are like those of the preceding one, club-shaped, with the four basidiospores arising from the rounded top. The fungus itself grows inside the herbaceous portions of living plants, breaking through the epidermis to form a single layer of basidia on the outside. There is no distinct fruit, other than this layer of basidia. The genus Exobasidium contains a harmful parasite of the cranberry.

Order 61. *Tremellales.* Jelly Fungi. These are mostly wood or ground inhabitants. The fruits are of moderate size and cushion-like or lobed in various ways. When wet, they are soft and jelly-like; when dry, very inconspicuous, dark, hard masses, of greatly reduced size. The basidia are split down lengthwise into four cells, each bearing on a long stalk a single basidiospore.

Order 62. *Auriculariales.* Ear Fungi. These resemble the foregoing order greatly in general habit, gelatinous nature of the fruit, etc. The essential difference is that the basidia are elongated and divided transversely into four cells, from each of which a stalk arises, bearing a single basidiospore. The common Jew's Ear (Auricularia) is very common as a brown, ear-shaped fungus on branches of trees.

The *Imperfect Fungi* constitute a group of fungi containing neary 17,000 species. They form in reality only an artificial group of heterogeneous species. Their sexual reproduction is unknown and they are grouped accordingly only by their modes of conidium formation or where no kinds of reproductive spores are known by their vegetative structures. As they are studied carefully, many of them are being found to be merely conidial or vegetative stages of fungi that belong to the class Ascomyceteæ or less often to the Basidiomyceteæ. It is possible that some of them are fungi that have utterly lost their sexual reproduction and reproduce now only asexually. In such a case, their exact kinship cannot be determined and they will have to remain in this group of Imperfect Fungi. For the sake of convenience, the fungi in this group are, so far as they reproduce by spores, distributed among three orders.

Order 63. *Sphæropsidales.* The conidia are produced within more or less rounded protective bodies (pycnidia) usually with an opening for the spores to escape. These fungi include some troublesome parasites of plants, e.g. —Phyllosticta (Fig. 19) which causes leaf spots on various plants, Septoria, the cause of Leaf Spot of Tomato, etc.

Order 64. *Melanconiales.* The conidia in this group are produced on rather short threads that are closely crowded side by side, usually underneath the epidermis of the host plant. They accumulate in such numbers as to burst the epidermis and allow them to exude a sticky mass. Here we have numerous species of Gloœosporium (Fig. 20).

Order 65. *Moniliales.* Molds. The spores in this group occur neither in rounded bodies (pycnidia) nor in packed threads under the epidermis (acervuli) but on more or less separate threads which emerge from the object on which the mold is growing in various ways. In Ramularia (Fig. 21) and Cercospora we have numerous parasites of leaves, the elongated conidia arising from short or elongated threads that emerge from the stomata of the host epidermis. Botrytis causes many diseases, as on onion, peony, lily, etc. Many species of Fusarium attack the potato.

Phylum VIII. Bryophyta.— Mossworts. The plants of this phylum are all massive, in contrast to the filamentous structures generally found in the preceding phyla, being composed of many layers of cells, which are aggregated into flat bodies (*thalli*) or leafy stems. They are typically terrestrial, although in the lowest family some species are still aquatic, while others have come out a little distance from the water upon the wet earth. All of the species are chlorophyll-bearing and none are either parasitic or saprophytic. Their reproduction is mostly sexual. The egg cell is invested from the first with a long-necked envelope, the archegone, which opens at the apex to permit fertilization. The antherids are compound, consisting of many small, cubical cells (each an antherid proper and producing a single sperm) surrounded by an enclosing layer of larger cells. The sperms are spirally curved and provided with two long flagella. After fertilization (which must take place in water, as in a rain drop) the egg divides repeatedly and gives rise to a globular or elongated cellular structure, some of whose interior cells ultimately divide internally into four spores each. The spores on escaping germinate and eventually give rise to new plants. The asexual reproduction, which is lacking in some species, is as follows: Upon some part of the plant, single cells (brood cells) or masses of cells (brood masses), grow on the ends of short hairs, and, falling off, grow directly into new plants. There are two classes.

Class 18. *Hepaticæ.* Liverworts. These are mostly supine, flat plants, attached to the ground by root hairs for nearly their whole length. By the deeper and deeper lobing of the margins of the thallus we find all gradations up to a leafy stem, with the leaf planes parallel to the stem axis. Such leafy stems are as distinctly two-sided (dorsiventral) as the undifferentiated thalli from which they are derived. There are about 4,000 species of liverworts, which may be arranged in three or four orders.

Order 66. *Marchantiales.* (Fig. 25). In this order are aggregated those liverworts in which the plant is thallose and the fruits indehiscent or dehiscent only by irregular or regular terminal openings. The antherids and archegones are on the upper side of the plant or the archegones apparently on the under side of special stalked receptacles. There are three families, the first of which, the Crystalworts (*Ric-*

ciaceæ), includes small, radiate, thallose plants, half an inch or so in diameter, floating on the water or growing on the wet earth. The antherids and archegones are sunken in the upper surface of the plant body. The fruits are spherical, stalkless and indehiscent and remain enclosed in the archegonial wall. Except for the outer layer of cells the whole fruit consists of spores. Riccia and Ricciocarpus are common. The Great Liverworts (*Marchantiaceæ*) are larger and dichotomous-spreading upon the ground. The thallus is ribbed in its longitudinal axis. The fruit, which is short-stalked, breaks open more or less irregularly at its apex and sets free the spores which are intermingled with elongated, sterile cells, the elaters. The archegones and frequently also the antherids are often produced on stalked portions of the thallus, the receptacles, as in Marchantia and Grimaldia (Fig. 25).

Order 67. *Anthocerotales.* Horned Liverworts. These are thin, flat, thallose plants having their antherids and archegones embedded in the upper surface. After fertilization, the egg develops into an elongated, somewhat club-shaped stalk, containing a large amount of assimilating tissues and a central "columella," the spores, intermingled with elaters being formed in the rather limited space between. This fruit may continue to grow at the base after the spores are ripe at the tip where it splits lengthwise into two valves to set the spores free. In this family, particularly in the genus Anthoceros (Fig. 26), the fruit (henceforward called sporophyte in the higher groups) is only partially dependent upon the thallose parent plant, obtaining water and mineral matters from it but manufacturing for itself most of the organic foods it requires for the nourishment of the spores.

Order 68. *Jungermanniales.* The Scale Mosses (Fig. 27) are leafy stemmed (or their simplest forms thallose) plants with their fruits (sporophytes) split vertically into four segments, setting free the spores and elaters. These little plants are frequently mistaken for mosses, which they resemble in external appearance. They grow commonly on trees, stones and sometimes on the ground. The more than 135 genera and 3,600 species may be divided into two families. The genera Jungermannia and Plagiochila (Fig. 27) are common in many parts of North America.

Class 19. *Musci.* Mosses. These are leafy-stemmed, terrestrial, rarely aquatic plants, usually erect and attached to the ground by root hairs on the lower part of the stem. The leaf planes are approximately at right angles to the stem axis and the leaves are usually in many rows, alternate and crowded, only rarely in two rows. The antherids and archegones are at the summit of the stem, sometimes together, oftener on separate shoots or plants; or at the ends of short lateral shoots. The fruit (sporophyte) resulting from the growth of the fertilized egg may develop a long stalk (as in most mosses) or be short stalked or almost stalkless. In the latter cases, however, the parent stem may grow out into a stalk (pseudopodium) which is not part of the sporophyte. The main portion of the sporophyte is enlarged and contains externally and internally considerable sterile tissue with an intermediate layer of sporogenous tissue. Mostly this "capsule" dehisces regularly, by slits or by the falling off of a lid. The spores on germinating produce a mass of green branching filaments (protonema) or a flat thallus, from which later the leafy stems bud off. There are over 12,000 species which may be arranged in three orders.

Order 69. *Andreæales.* The Black Mosses (Fig. 28) are small, leafy, dark plants, usually growing on rocks. Their leaves are thickish and composed of uniform cells. The sporophyte is raised on a stalk (pseudopodium) of the leafy plant itself. It opens to permit the escape of the spores by four or eight longitudinal slits. The protonema is thallose. The single genus Andreæa contains over 100 species.

Order 70. *Sphagnales.* The Peat Mosses (Fig. 29) are large, leafy, pale-green plants growing in bogs. Their leaves are thick and are composed of dissimilar cells, some containing chlorophyll and others with perforated walls so as to admit water freely. The sporophyte is raised on a pseudopodium and is itself short-

stalked. It opens by a circular lid to permit the escape of the spores. The protonema is thallose. There is but one family, containing the single genus Sphagnum, with over 250 species. These are found over nearly the whole world. They are highly esteemed by gardeners for packing plants, on account of their power of retaining moisture for a long time. Some species possess great value for surgical dressings.

Order 71. *Bryales.* The True Mosses (Figs. 30 and 31) are small to large plants, exceedingly variable as to habitat; they are found on trees, on the ground, on rocks and a few species in water. Some form large cushions a foot or more in diameter and several inches thick, while others are scattered and but a few millimeters in height. The leaf cells are all more or less similar and chlorophyll-containing. With a very few exceptions the sporophyte is long-stalked and the capsule is usually dehiscent by a circular lid. In the family *Phascaceæ* the capsules of the minute plants are short-stalked and indehiscent; but in the remaining families of the order the capsule develops a lid which on falling off reveals an opening usually provided with a fringe of teeth in one or two rows. These may number 4, 8, 16, 32 or 64 and constitute the «peristome.» The protonema is typically filamentous. The 12,000 or more species are divided among nearly 60 families. Among the commoner mosses are Phascum, Orthotrichum, Funaria, Bryum (Fig. 31), Mnium, Polytrichum, with sporophytes terminal to the main stem, and Fontinalis (an aquatic form), Neckera, Leskea, Climacium and Hypnum, with sporophytes arising from short lateral shoots.

Phylum IX. Pteridophyta.— Ferns. The plants of this phylum present a distinct alternation of two generations, gametophyte and sporophyte, respectively. The gametophyte is a small thallose plant resembling the simpler liverworts and bears antherids and archegones of the same plan as in those plants. The sperms are spiral and multiciliate. The fertilized egg develops into a multicellular structure which is at first enclosed within and dependent upon the gametophyte, but which soon develops roots, stem and leaves of its own and attains complete independence of the parent gametophyte. This sporophyte has true vascular bundles. It does not develop its spores until it has reached a comparatively large size. The leaves are mostly large and broad, and are clustered near the apex or scattered along the stem, but never in whorls. The stem is solid and upright or horizontal, in most forms subterranean. In contrast to the Bryophyta the sporophyte is the long-lived generation while the gametophyte persists only until the former has established itself independently. In further contrast the sporophytes of Pteridophyta develop only a relatively small part of their cells into spores. These are produced in small «sporangia» which may originate within the tissues of the plant or as external structures, always as parts of leaves. These leaves are mostly not different from the vegetative leaves, although in some species the «sporophylls» are much differentiated. Asexual reproduction occurs in a few species by the formation of little bulblets on the leaves. About 3,800 species are recognized, distributed very unequally in two classes.

Class 20. *Eusporangiatæ.* This class contains only a small number of existing species, but seems in the Paleozoic era to have been very numerously represented. Its chief distinction lies in the development of the sporangia from internal cells of the leaf. Three orders may be recognized.

Order 72. *Ophioglossales.* Adder-tongue ferns. The gametophytes of this order are subterranean and tuberous; the sporophyte possesses short, subterranean stems and usually but one leaf at a time. This is simple or compound. The spore-bearing leaves are divided into a spore-bearing and vegetative part. The chief genera of the single family are Ophioglossum (Fig. 32), the adder-tongue fern, and Botrychium, the grape fern.

Order 73. *Marattiales.* The Ringless Ferns have flat, green, liverwort-like gametophytes and large-leaved, thick-stemmed sporophytes, the leaves on some species reaching a length of 10 to 15 feet. The sporangia are formed on the dorsal side of the leaf, arising within the leaf but growing so as to project prominently. In most of the few genera the crowded sporangia are united into compound structures called «synangia.» All the species are tropical. Marattia (Fig. 33), Angiopteris and Danæa are grown in the larger conservatories.

Order 74. *Isoetales.* The Quillworts. The sporophytes of this order are plants from an inch to a foot in height, rooted in the mud in or near the water of shallow ponds and ditches. The stem is very short and sheathed by the broad bases of the narrow, pointed leaves. The single sporangium is borne near the base on the upper side of the leaf. Two kinds of spores are produced in separate sporangia; megaspores and microspores, the former large and less numerous, the latter small and very numerous. Both sorts may be produced on the same plant, the megaspores on the outer leaves, the microspores on the inner. The gametophytes are accordingly of two kinds, each retained within the spore wall; megagametophyte, producing archegones, and, after fertilization of the egg, nourishing the embryo sporophyte and microgametophyte, reduced to but one vegetative cell and one antherid producing four multiciliate, spiral sperms. The single genus Isoetes (Fig. 34) contains about 60 species.

Class 21. *Leptosporangiatæ.* This class is distinguished by the mode of origin of the sporangia, which arise from the superficial cells of the leaves, usually dorsally, and mostly are stalked. They are grouped into characteristic groups (sori) which usually have a definite protective covering (indusium) when young. There are two orders.

Order 75. *Polypodiales.* Common Ferns. Spores of but one kind are produced so that the gametophytes are also all alike, usually with both antherids and archegones on the same individual. Sporohytes with large, usually compound leaves, with prostrate, underground stem or with stem vertical and very short, or even tree-like in dimensions. Of the eight families into which the 3,500 or more species are distributed the very great majority are found in the *Polypodiaceæ.* Among the genera common in North America are Polypodium, Dryopteris, Asplenium, Adiantum, Pteridium, Woodsia (Fig. 35), etc.

Order 76. *Marsiliales.* The Water Ferns

either root in the mud in or near the water or float free on the surface. The sporophylls are folded together to form a closed "sporocarp" in one family, while in the other the indusium is indurated and completely encloses the sorus. The spores are of two kinds as are accordingly the gametophytes. Marsilia (Fig. 36) resembles a four-leaved clover. It roots in the mud. Salvinia (Fig. 37) and Azolla are floating plants and have no resemblance to the common ferns, to which they are, however, evidently related.

Phylum X. CALAMOPHYTA.— The plants of this phylum that survive are only about 25 in number, but these are the remnant of a large group of three distinct classes and as many orders, that flourished in Paleozoic times. The gametophytes are known only from the modern representatives of the phylum. They are flat and liverwort-like, producing antherids and archegones and multiciliate sperms, all essentially like those of the Pteridophyta. The sporophyte consists of cylindrical stems, jointed at the nodes where the leaves arise in whorls. If branched, as is frequently the case, the branches arise in whorls also. The ancient plants were both arboreal and herbaceous, but the modern survivors are all herbaceous.

In some forms the stem was solid but in others hollow. The sporangia are borne on modified leaves collected into a terminal cone. In one class there were two kinds of spores; in the others but one kind.

Class 22. *Sphenohyllineæ.* The Wedge-leaved Calamites were herbaceous and woody plants of Paleozoic times with solid, jointed stems and whorls of wedge-shaped leaves. The spores were of only one kind (isosporous). Long since extinct. One order.

Order 77. *Sphenophyllales.* Characters of the class.

Class 23. *Equisetineæ.* Horsetails. These are herbaceous plants extending from the Paleozoic to the present era. The stems are hollow and jointed and the leaves are united at

FIG. 37.— One of the Floating Ferns (Salvinia); considerably reduced.

their bases to form a sheath at each joint, with a tooth to represent the reduced blade of each leaf. The sporophylls are shield-shaped and produce but one kind of spore.

Order 78. *Equisetales.* This order with but one family and one surviving genus (Equisetum, Fig. 38) is found in all parts of the world except the cold regions. Their stems are green and in some species the epidermis is so filled with silica that they were formerly used for scouring cutlery, whence the name "scouring rush." They are frequently known as "joint rushes."

38 39 40

FIG. 38.— Plant of a Horsetail (Equisetum), green plant at the right, pale spore-bearing plant at the left; much reduced.
FIG. 39.— Part of a Ground Pine plant (Lycopodium), with spore-bearing cones; much reduced.
FIG. 40.— Part of a Little Club Moss plant (Selaginella), with many spore-bearing cones; somewhat reduced.

Class 24. *Calamarineæ.* The Calamites were Paleozoic plants, long extinct, forming trees with woody stems which were hollow and capable of increasing in thickness. In their terminal cones, most of them produced two kinds of spores (heterosporous), hence it must be that the gametophytes were also of two kinds.

Order 79. *Calamariales* is the only order recognized, with two families.

Phylum XI. LEPIDOPHYTA.—The Lycopods are represented now by about 700 species of herbaceous plants, but in Paleozoic and succeeding ages immense trees occurred whose remains form part of the coal deposits in various parts of the world. The sporophytes of all forms possess solid stems, sometimes unbranched, more often branched and clothed by scale or needle-like, spirally arranged, overlapping leaves. The leaves in the modern forms are green and functional. The spores are borne in sporangia which are produced singly in the axil or on the upper surface of the sporophylls. The latter are more or less similar to the vegetative leaves and grouped into a terminal cone. The gametophytes are known for only a part of the living forms and for very few of the fossil ones. The sperms are spiral and possess two long flagella, resembling those of the Bryophyta instead of the Pteridophyta or Calamophyta. The embryo sporophyte is nourished for a considerable time within the gametophyte tissues. Two classes may be distinguished.

Class 25. *Lycopodineæ.* Lower Lycopods. These are only known in their modern forms, the fossil ancestral forms being entirely wanting. The sporophytes are herbaceous, evergreen, mostly trailing plants, sending up cone-bearing stems here and there. The spores are of but one kind. The gametophytes are more or less tuberous and sometimes underground. They bear antherids and archegones on the same gametophyte.

Order 80. *Lycopodiales.* One, or doubtfully two, families. The chief genus is Lycopodium (Fig. 39), of economic value as a source of Lycopodium powder and of the "Ground Pines" so extensively used for Christmas greens.

Class 26. *Lepidodendrneæ.* The Higher Lycopods consisted so far as fossil records go of trees and of herbaceous plants; their modern representatives are entirely herbaceous. They are in general like the foregoing class but differ in that the leaves and sporophylls possess a scale-like process on the upper surface, the ligule, and the spores are of two kinds. The gametophytes are contained within the spore walls and possess no chlorophyll. In the microgametophyte there is but one vegetative cell and the antherid is single, producing but few sperms. The megagametophyte begins to form long before the sporangium reaches maturity and opens. In some fossil species this development proceeded so far that the archegone was fertilized while the megagametophyte was still retained in the sporangium — the beginning of seed production.

Order 81. *Selaginellales.* The Club Mosses are the modern representatives of this once very important class. They are small, mostly inconspicuous, moss-like, evergreen plants, resembling miniature ground pines. The single genus Selaginella (Fig. 40) contains about 500 species, mostly tropical, but a few occurring throughout the United States and in Canada. A few species are grown in greenhouses.

Order 82. *Lepidodendrales.* Extinct, Paleozoic and Mesozoic plants; mostly trees, with woody stems, capable of increasing in thickness. Four or five families. Some of these plants formed very tall trees.

Phylum XII. CYCADOPHYTA.— Although rudimentary seeds were formed, apparently, in one or two long since extinct genera of the Phylum Lepidophyta, the Cycadophyta were the first group in which seeds were regularly developed. The gametophytes are of two kinds, corresponding to the two kinds of spores. The microspores are wind carried. Even before they leave their microsporangium they begin to develop into the microgametophyte. This is at first contained within the spore wall and consists of a vegetative portion of one to several cells and a single antherid. The four megaspores are produced within a very large megasporangium surrounded by a protective "integument" which grows up around it from the base, entirely enclosing it except for a small apical opening, the micropyle. One megaspore enlarges at the expense of the other spores and then, within the megasporangium, produces a many-celled megagametophyte in which arise several archegones. The wind-borne microspore (or rather young microgametophyte) that happens to fall into the micropyle of the integument appears in some of the fossil forms to have enlarged in size and set free numerous sperms, in other fossil forms and all modern ones it sends out a tubular outgrowth to be regarded as an extension of the antherid which roots itself in the tissues of the megasporangium and thus obtains nourishment. Within this antherid are produced two to many ovoid, multiciliate sperms which escape and swim to the archegones which have been exposed by the breaking down of the intervening megasporangial tissue. The fertilized egg produces an embryo sporophyte which lies wholly within the megagametophyte and is nourished by it. After it had reached a certain size its growth stops, the integuments harden and the whole megasporangium falls off as a mature seed. Under favorable circumstances the embryo sporophyte then resumes its growth and emerges from the seed, or as we say, the seed germinates. The sporophytes in this phylum are all woody, some with underground stems, others with erect stems, unbranched or branched, forming large trees in many cases. In the lower classes the leaves are fern-like or at least large and pinnate; in their higher forms they are long and narrow or medium-sized and fan-shaped, always with numerous longitudinal veins. The sporangia are borne on the under side or edges of scarcely or much modified leaves which may be scattered among the vegetative leaves or grouped into cones.

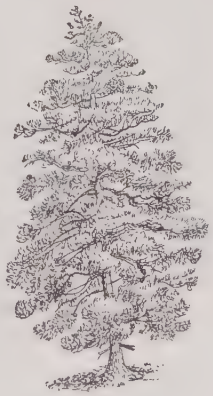
There are somewhat over 100 species of this phylum now existent, representing two out of the four classes. Many more species, in all four classes, were present in Paleozoic and Mesozoic times. Indeed, the present species represent but meagre remnants of a once dominant vegetation.

Class 27. *Pteridospermeæ,* with the single order 83. *Lyginopteridales.* Seed Ferns. This group is only known from fossils of the Paleozoic era. The plants were woody stemmed with secondary thickening, and fern-like as to foliage. The microspores were borne in sporangia similar in structure and location to those of the Order Marattiales in the Phylum Pteridophyta. The megaspores were borne in sporangia terminal to the lobes of unmodified or considerably modified leaves.

Class 28. *Cycadineæ.* Cycads. Only one order (Order 84, *Cycadales*) is now represented, confined to the tropical and sub-tropical

41

42



43

FIG. 41.— Plant of a Cycad (Cycas); greatly reduced.

parts of the world. These are plants with erect, woody, little branched stems (occasionally subterranean), with terminal clusters of large, thick, pinnate leaves. The two kinds of sporophylls are produced on separate plants, in ter-

minal cones. They are much smaller and entirely unlike the vegetative leaves in the male (microsporophyll) cones and in the female cones of all but one genus (*Cycas*) in which the loose terminal cone resembles a cluster of stunted leaves with seeds borne at the edges of the lower parts of the rachis. The development of the male gametophyte and of the sperms has been fully worked out in this group. The genus Cycas (Fig. 41) is frequently grown in large greenhouses. Zamia occurs in Florida and in the tropics. It is used as a source of starch.

Class 29. *Bennettitineæ*. The single order of this class (Order 85, *Bennettitales*) contains many species of Mesozoic plants resembling vegetatively the plants of the foregoing class (*Cycadineæ*). They differ in that the microsporophylls and megasporophylls are present in the same cone. These cones are lateral, axillary to the leaves, and numerous. They are surrounded at the base by large leaves comparable in position to the sepals and petals of a Magnolia flower. Above these are the microsporophylls, many in number and much divided, like fern leaves, bearing at the extremities of the divisions the microsporangia. Above these, occupying the centre of the "flower" are numerous simple megasporophylls, reduced to a stalk terminated by a megasporangium, and intermingled with sterile bracts. The seed is like that of the preceding order. The chief genus is Bennettites. The plants have great interest because of the light they throw on the probable ancestry of the Flowering Plants (Phylum XIV).

Class 30. *Cordaitineæ*. The trees which make up this class were often very large, so far as they are known. The trunk was usually branched, the ultimate branches being clothed with the leaves, giving the plants a tufted appearance. The leaves were thickish and parallel-veined, in some cases fan-shaped, mostly, however, long and narrow. The microsporophylls occur in small cones; the megasporophylls in imperfectly understood, complex cones. The seeds are of the same general type as in the two foregoing phyla and were in all probability, as is the case in Ginkgo (Fig. 42), fertilized by motile sperms, either set free directly from the microgametophyte or (as in Ginkgo) from a long tube produced by it. Two orders may be distinguished with certainty, others will probably have to be placed here.

Order 86. *Cordaitales*. Extinct, Paleozoic trees with elongated, narrow leaves and complex female cones.

Order 87. *Ginkgoales*. Maidenhair Trees. In Mesozoic, and probably Paleozoic times, there were many species of this order, but they are represented now by a single species native to China and extensively cultivated there and in Japan and to some extent in this country, *Ginkgo biloba* (Fig. 42). The trees are freely branched and possess fan-shaped leaves, notched at the middle of the outer edge. The microsporophylls are in small, loose cones; the seeds are borne singly or in twos at the apex of a long stalk.

Order 88. *Gnetales*. This order, consisting of three families, each with a single genus, is of very doubtful affinity. It may be related to this class or to the preceding one or its relationship may be elsewhere. The plants are more or less woody, with opposite leaves. The stems in two genera are green. The leaves are large or reduced to scales. The microsporophylls are borne singly or a few together in the axils of scales which are arranged in cones; i.e., the male cones are compound. Apparently the same is true for the female cones. The ovules (the term applied to the undeveloped seed) are naked. The sperms are not ciliated. There are three genera. Ephedra (Fig. 44) is found in arid regions, e.g., Arizona and

44 45 46

FIG. 44.— Fragment of a Joint-fir (Ephedra), with clusters of microsporophylls; considerably reduced.
FIG. 45.— Plant of Water Plantain (Alisma), in flower; much reduced.
FIG. 46.— Plants of a Lily (Lilium), in blossom; greatly reduced.

the Mediterranean Basin. The plants of this genus are leafless and jointed. Gnetum with netted-veined, opposite leaves, forms climbing woody vines or even trees, in tropical regions. Tumboa, from southwest Africa, has a radish-shaped root surmounted by a short thick stem, reaching a thickness of a yard or more and bearing two, opposite, foot-broad leaves, several yards long.

Phylum XIII. STROBILOPHYTA.— Conifers. The plants of this phylum are all woody, with secondary thickening of the stem. With the exception of a few low shrubs all are trees, some of them of great dimensions. The spores are of two kinds, megaspores and microspores. They are borne in separate cones on the same or on different plants. The megaspore is retained within the megasporangium (ovule) while it develops into a megagametophyte of a large number of cells with several archegones. The microspore, even before it leaves its sporangium, has begun its development into a gametophyte, by the cutting off of one or two small vegetative cells, the remainder being the antherid. This is carried by the wind to the megasporangium, and then the antherid begins to elongate, boring its way through the megasporangium tissue until the enclosed gametophyte with its archegones is reached. This tube (pollen tube) enters an archegone and one of the two non-ciliated sperms fertilizes the egg. The embryo develops much as in the preceding phylum, resulting in the formation sooner or later of a mature seed. The megasporangium (ovule) and resulting seed are borne on the open surface of well-developed or much reduced sporophylls which may be united into large cones or into small cones with only one or two of the sporophylls functional. The 400 living species form but one class (Class 31. *Pinoideæ*) with two orders.

Order 89. *Abietales*. The trees (rarely shrubs) of this order are resinous. The foliage of the majority of species is evergreen, the

leaves being scale-like and appressed to the twig or needle-like. The megasporangial cones consist, usually, of many scales which are usually woody, but in some genera the cone scales are fleshy at maturity. The seeds are dry and hard, externally. The six families contain many trees of the utmost economic value. The commoner are Pinus (pines, Fig. 43), Picea (spruces), Larix (larches), Abies (firs), Sequoia (redwood and big-tree), Cupressus (cypress), Juniperus (junipers), Thuya (arborvitae), Tsuga (hemlocks).

Order 90. *Taxales.* The plants of this order resemble closely those of the preceding one, but the megasporophylls are usually single. The seeds are hard-shelled within and fleshy externally. Three families may be distinguished. The Yew of Europe and Ground Hemlock of North America belong to the genus Taxus. Podocarpus is an important tree of the Southern hemisphere.

Phylum XIV. ANTHOPHYTA.—The Flowering Plants. This immense phylum includes plants varying from great trees on the one hand to minute herbs on the other. The vast majority are chlorophyll-bearing, but a few species lack chlorophyll and are saprophytes or even parasites. The leaves are most typically broad with more or less netted venation, but in many groups the venation is parallel, and narrow leaves are found in some plants of nearly every large subdivision of the phylum. The foliage may be evergreen or may fall before the new leaves appear. The plants may live only a few weeks or for hundreds of years. The microspores (pollen) are borne in modified sporophylls (stamens), consisting of a stalk ("filament") bearing usually four microsporangia (collectively, with the intervening tissues, known as the anther). The megaspores are produced in megasporangia (ovules) borne on megasporophylls (carpels) which are folded together and united at the edges or with the edges of adjacent megasporophylls to form closed cavities in which the ovules lie. These structures are known as pistils and are considered as simple if they consist of one megasporophyll and compound if two or more megasporophylls are united to form the pistil. Only one megaspore develops to maturity and produces a gametophyte. The latter (called embryo-sac) by division of the nucleus of the megaspore possesses eight nuclei of which six are set off by the organization of cells (but not necessarily with cell walls). One of these naked cells is the egg. The microgametophyte consists simply of one antherid with its tubular extension (pollen tube) which grows down through the tissues of the pistil and through the megasporangium (ovule) tissues to the egg which is fertilized by one of the sperm nuclei. The other sperm nucleus unites with the two nuclei at the centre of the embryo-sac and this stimulus leads to the resumption of the growth of the gametophyte to form the nutritive tissue (endosperm) used for the nourishment of the developing embryo.

The sporophylls are grouped in typical cones (called flowers) or these are much reduced in structure. The apical portion of the cone is occupied by the pistils or pistil; below these are the stamens and next the petals, showy modified leaves, and the sepals, usually green modified leaves that enclose the whole flower in the bud. In the primitive groups that show the closest relationship to the Bennettitales, the presumptive ancestors of this phylum, the sepals, petals, numerous stamens and numerous pistils are all spirally arranged in a large cone (e.g., flower of Magnolia), but as the evolution progresses we find the size of the flower and the number of each kind of part reduced in connection with modification of the spiral arrangement to whorled arrangement and the union of adjacent parts. Thus the flower of the Pink Family may have five whorls of parts, five to a whorl, viz., five sepals, five petals, two whorls of five stamens each and five megasporophylls united into one compound pistil. Besides reduction in number we may find actual loss of certain parts; thus many flowers lack petals and some lack sepals also. In some plants the stamens and pistils are found in separate flowers, either on the same plant (monœcious) or on different plants (dicœcious). The more than 132,000 species are divided into two unequal classes and 32 orders.

Class 32. *Dicotyledoneæ.* The Dicotyledons are trees or shrubs with true wood, increasing in thickness by means of a cylindrical layer of cambium, or herbs whose vascular bundles, with few exceptions, also undergo secondary thickening. These bundles are mostly arranged equidistantly from the centre of the stem in one series. The leaves are mostly broad and net-veined. They are scattered along the stem or whorled or very often opposite. The parts of the flowers are most frequently in fives or fours, rarely in threes. The young seedling possesses two seed leaves (cotyledons). The first order of this class shows the greatest affinity to the Order Alismatales of the next class probably having given rise to it in the course of evolution. Likewise in it are shown most clearly the points of resemblance to the Bennettitales (*Phylum Cycadophyta*) from whose close allies the Anthophyta are believed to have evolved. The first 14 orders, from Ranales to Lamiales, inclusively, represent a line of development in which one structural idea remains predominant, with very few exceptions, viz., the pistil, stamens, petals and sepals are attached successively lower down on the elongated or short, but never saucer or cup-shaped flower axis. Sometimes the axis is flattened, in which case the points of attachment are successively further from the centre of the flattened area. The pistil or pistils, therefore, are superior. Beginning this line come orders in which the various parts are numerous and separate. Reduction in number is the first noticeable feature. Soon, however, the union of pistils to form a compound pistil appears. The number of parts in the whorls of sepals, petals, stamens and carpels becomes prevailingly established at five with two whorls of stamens at first, one soon disappearing. The number of carpels then begins to be reduced, reaching two for the higher orders. Finally we find certain stamens disappearing from the whorl. All along the line petals may disappear and sometimes even the sepals. The sexes may become separated in different flowers. With these changes going on, sometimes within one order it is difficult to make a characterization that will cover all the plants in the order without going to too great length. Indeed, were it not for so many intermediate forms we would

hardly be able to justify the placing of such extremely different forms in one order as will be found here given.

Order 91. *Ranales.* Trees, shrubs or woody vines or herbaceous plants, mostly with alternate leaves (but opposite leaves prevail in some families). The flowers have their parts mostly spirally arranged upon the axis and free from each other. Mostly the flowers are radially symmetrical (regular), but in some cases they are zygomorphic and possess only bilateral symmetry. The pistils are attached to the axis above all other parts of the flower, i.e., they are superior. The carpels vary from many (typically) to few or even one; they are free; in a few cases only, being united into a compound pistil. The stamens are mostly numerous or indefinite in number, reduced to few in some cases. The seeds mostly contain a small embryo in copious endosperm. The approximately 5,600 species represent 24 families distributed all over the world. In temperate North America the Buttercup (*Ranunculus,* Fig. 47), Mag-

FIG. 47.—A Buttercup (Ranunculus) in blossom; greatly reduced.

nolia, Barberry (*Berberis*), Sassafras, Lotus (*Nelumbo*), etc., represent the commoner families of the order.

Order 92. *Malvales.* Trees, shrubs and herbs with mostly alternate leaves. The radially symmetrical flowers typically are of medium size to large, with five sepals and five petals and numerous stamens united by their filaments into one or several groups. The pistil is superior and compound, with many loosely united carpels. By various steps we find also in this order plants in which the petals are wanting, or the number of stamens has been reduced to five or even to one (*Ficus,* the Fig), or the number of carpels is likewise small. The seeds may contain endosperm or not. The over 3,800 species represent about a dozen families, of which the following are important examples: Cacao (Theobroma), Cotton (Gossypium), Linden (Tilia), Elm (Ulmus), Hemp (Cannabis), Nettle (Urtica). Some of the families are strictly tropical in their distribution, others are world-wide.

Order 93. *Sarraceniales.* A small order of less than 100 species and consisting of two families. The plants are all herbaceous and possess leaves modified for catching and digesting insects. The radially symmetrical flowers have separate sepals and petals and a few to many stamens. The pistil is superior and compound and consists of three to five carpels with many seeds with endosperm. Perhaps this order ought to be united with the preceding one.

Order 94. *Geraniales.* This order, like the Malvales, is to be looked upon as derived from the Ranales. The plants are trees and shrubs, or herbs, with mostly alternate leaves. The flowers are mostly radially symmetrical. The petals and sepals are mostly in fives and separate; the stamens are mostly in one or two whorls of five. The superior compound pistil consists of five, sometimes fewer, mostly weakly united carpels, with many or but few, usually pendent ovules. As in other orders, we find a tendency toward reduction in parts in certain lines of development. Thus some of the over 9,200 species making up the 22 families of this order have lost their petals and in some cases the sepals have disappeared also. Similarly a reduction in the number of stamens shows itself at frequent intervals. As representatives of the commoner families may be mentioned the cultivated Geranium (Pelargonium), Wood Sorrel (Oxalis), Touch-me-not (Impatiens), Flax (Linum), Orange (Citrus), Castor Bean (Ricinus), etc.

Order 95. *Hypericales.* Nearly all the 3,100 species of this order are trees or shrubs, comparatively few being herbs, these being mostly extra-tropical, while the vast majority of the families are tropical. In a few families zygomorphy of the flowers is strongly developed; the majority, however, are radially symmetrical. The kinship to the Ranales from which the order probably arose is shown by the usually large number of stamens (rarely reduced to five), and by the separate sepals and petals and superior pistils. The latter are compound, consisting of several, rarely as few as two, carpels, often joined by their edges, so that the ovules are parietal, sometimes with axial attachments of ovules. The seeds mostly have no endosperm. The 20 families of this order are represented in temperate North America by Saint John's Wort (Hypericum), Violet (Viola), Rockrose (Helianthemum), while in warmer regions of the world we find in cultivation Tea (Thea), Papaya (Carica) and Passion Flower (Passiflora).

Order 96. *Papaverales.* Trees or shrubs in some cases, but mostly herbs, usually with colored juices or pungent properties. Flowers radially or occasionally bilaterally symmetrical. Sepals and petals separate, usually in whorls of five or four, rarely numerous and spirally arranged; stamens many and spirally arranged or in one or two whorls and few in number; pistil superior, compound, of two to six, rarely more, united carpels; ovules mostly parietal; seeds with or without endosperm. Arising from the Ranales this group shows progression from forms with several carpels, many stamens (spirally arranged) and numerous petals and sepals toward those plants with two carpels, two or one whorl (sometimes incomplete) of stamens and five or four petals and sepals (or even two sepals). The seven families include nearly 3,000 species. The Poppy Family (*Papaveraceæ*) includes many plants frequently grown for the beauty of their flowers as well as several of medicinal value, e.g., the Opium Poppy (Papaver). The Mustard Family (*Brassicaceæ*) contains very many troublesome weeds and some important food plants such as

Cabbage, Turnip, Cauliflower, Mustard, etc. (Brassica), Radish (Raphanus), various kinds of Cress and other plants of less importance.

Order 97. *Chenopodiales.* Trees or shrubs, or far more numerously herbs, mostly free from harmful properties. Flowers radially symmetrical; sepals and petals usually present and in whorls of five, or in some families the petals lacking. The stamens are in two whorls or the inner whorl may be lacking; occasionally they are more numerous or fewer. The pistil is superior (with rare exceptions), and composed of several or few, most often five or three, united carpels. The ovules are borne axially or basally in the mostly one-loculed ovary. The seeds usually have a curved embryo embedded in endosperm. Nearly 4,500 species are included in this large order which comprehends 18 families. Its distribution is world-wide. As in the preceding orders the more primitive forms show their close kinship to the Ranales by their pistils consisting of several carpels; their many stamens reduced to two whorls as the first step and next, to one whorl, and their separate petals and sepals. This order is marked by the great frequency with which the loss of the petals occurs, their function being taken by the sepals or neighboring bracts which become showy, or the flowers becoming small and inconspicuous. Many of our commonest weeds belong to the latter type, such as Lamb's Quarters (Chenopodium), Pigweed (Amaranthus), Knotweed (Polygonum). Among the plants with more showy flowers are the Pink (Dianthus), Portulaca, etc. The Willow (Salix) and Poplar (Populus) are the most important trees of the order. They possess no petals.

The next seven orders are probably to be derived directly or indirectly from the more primitive forms of the foregoing order, i.e., those forms with parts in whorls of five each and all parts separate except the united carpels; with two or more whorls of stamens and with a tendency toward a unilocular ovary with free central placenta.

Order 98. *Diospyrales* (*Ebenales*). Trees or shrubs, mostly of warm climates. Flowers regular and perfect or sometimes the stamens and pistils in separate flowers. Sepals more or less united, as are the petals. Stamens in two or sometimes one or three whorls, usually attached to the united petals (corolla). Pistil of several united carpels with one or a few ovules in each carpellary cavity, usually superior. Seeds usually large, mostly with endosperm. This order is probably derived from some of the woody forms of the preceding order with the union of sepals and of petals as a forward step. The ovary is still mostly of several carpels and the stamens in more than one whorl. The four families contain over 1,100 species. The family *Sapotaceæ* contains some valuable tropical fruits, e.g., sapodilla (Sapota). The genus Diospyros of the *Diospyraceæ* (*Ebenaceæ*) furnishes the persimmon as well as many kinds of ebony.

Order 99. *Ericales.* Trees, shrubs and herbs of tropical and temperate climates. Flowers regular, perfect, with parts in fives or fours. Sepals and petals usually more or less united. Stamens in two or more often one whorl, mostly free from the petals. The superior (rarely inferior) pistil is compound, of two to many, mostly five or 10 carpels, each with several minute seeds with endosperm. A few species are parasite or saprophytes. The family *Ericaceæ* is especially associated with (but not confined to) heaths or peat bogs where, for example, the Cranberry (Oxycoccus) abounds. The order contains over 1,700 species in six or seven families.

Order 100. *Primulales.* This order, consisting of trees, shrubs and mainly herbs, appears to have arisen, like the two foregoing orders, somewhere in the Order Chenopodiales. The characters are more nearly like those of the Pinks (*Dianthaceæ*) than some of the other families. The flowers are regular, with parts mostly in fives. The stamens are mostly in only one whorl (the inner one, alternating with the sepals) sometimes with rudiments of the outer whorl as "staminodia." The pistils are mostly superior, composed of two to several carpels, usually as many as the petals, with a single locule. Seeds with endosperm. Of the approximately 1,600 species in this order the Primrose family (*Primulaceæ,* Fig. 48) is the

48 49 50 51

FIG. 48.— Flower and leaf of a Primrose (Primula); greatly reduced.
FIG. 49.— A Foxglove (Digitalis), in bloom; greatly reduced.
FIG. 50.— Flowers and leaf of Strawberry (Fragaria); greatly reduced.
FIG. 51.— Leaf and flower-heads of Compass Plant (Silphium), one of the Asterales; greatly reduced.

largest in temperate regions. The Plantains (Plantago) probably are related to this family but their position is uncertain.

Order 101. *Gentianales.* Trees and shrubs, less frequently herbs, largely of the warmer parts of the world, frequently with milky latex. Flowers regular, with sepals and petals united, usually in whorls of five; stamens as many as the petals (rarely only two), being the outer whorl and alternating with the petals. Pistil superior, composed of two, rarely four (sometimes loosely) united carpels, with mostly many ovules in each locule. Endosperm mostly present in the seed. Leaves mostly opposite. The 4,700 species represent six families, of which the following representatives may be mentioned: Lilac (Syringa), Olive (Olea) and Ash (Fraxinus), in the Olive Family (*Oleaceæ*); Gentian in the family of that name (Gentiana in the *Gentianaceæ*); Oleander (Nerium), Periwinkle (Vinca), and several important rubber plants in the Dogbane family (*Apocynaceæ*); Milkweed in the family of that name (Asclepias in the *Asclepiadaceæ*).

Order 102. *Polemoniales.* Trees and shrubs or (in temperate regions especially) more often herbs with mostly alternate leaves. Flowers regular, or somewhat bilateral in the higher families of the order; sepals and petals mostly

in fives and united; stamens one whorl (the outer) alternating with the petals and equaling them in number. Pistil superior, consisting of five or three, in the higher families of two united carpels with two to many ovules to a carpel. Seeds mostly with endosperm. The Phlox family (*Polemoniaceæ*) shows great resemblance to the Primrose family in Order 100, but differs in having the single whorl of stamens the outer instead of the inner one, in having the number of carpels reduced and in having one locule for each carpel instead of one locule for the whole pistil. This order contains about 4,100 species and seven families. The Potato (Solanum), Forget-me-not (Myosotis), Dodder (Cuscuta), Morning Glory (Ipomœa) and Phlox represent respectively five of these.

Order 103. *Scrophulariales.* Trees, shrubs and (mostly in temperate regions) herbs, more often with opposite leaves. Flowers irregular, often strongly two-lipped, the sepals and petals usually in fives and united; the stamens representing the outer whorl, but with one or three missing or represented by stamonodia. Pistil superior and composed of two (rarely four) united carpels, with many ovules in the two or sometimes single locule. Seeds largely with endosperm. About 7,100 species and 10 families. The Foxglove (Digitalis, Fig. 49), Catalpa, Sesame (Sesamum), Broomrape (Orobanche), and Acanthus belong to this order.

Order 104. *Lamiales.* Trees, shrubs and herbs with mostly opposite leaves. Flowers usually strongly zygomorphic, sepals and petals united, in fives; stamens representing the outer whorl and, therefore, alternate with the petals, usually one or three missing. Pistil superior, of two united carpels, but often four or more loculed, with one ovule in each locule. The seeds contain little or no endosperm. Over 4,100 species, in four families. In the Verbena family (*Verbenaceæ*) are found such herbs as the Verbena and such trees as the Teak (Tectona). The Mint family (*Lamiaceæ*) contains many plants cultivated for seasoning, e.g., Sage (Salvia), Thyme (Thymus), Mint (Mentha), etc.

Contrasted to the structural idea, hypogyny, running throughout the foregoing 14 orders, that of the remaining 10 orders of the class Dicotyledoneæ is perigyny and epigyny. The axis of the flower is expanded below the region of attachment of the pistils or pistil into a disc or cup on the upper surface or edge of which the stamens, petals and sepals are attached, so that they arise at a level with the body of the pistil or above it. This is called perigyny if this cup-like axis does not grow fast to the pistil that it surrounds and epigyny if the enclosed pistil is grown fast to the investing axis-cup. In the most primitive families of this series the pistils are numerous and simple and the axis-cup shallow. Progression is along several lines; thus the number of pistils may be reduced to one simple pistil, or after the reduction has reached a certain point the remaining pistils may unite into a compound pistil. This may be free from the axis-cup or as evolution progresses this may grow fast to it so that we now find an inferior, compound pistil. Similarly the large, indefinite number of stamens of the more primitive families finally becomes reduced to one whorl of as many stamens as there are petals, or some stamens may even be missing in this whorl. The primitive families of the first order of this series are certainly closely related to the more primitive families of the order Ranales, which in its turn shows kinship to the ancestral forms among the Bennettitales.

Order 105. *Rosales.* Trees, shrubs and herbs with mostly alternate leaves. The flowers are mostly regular, but in one side line of evolution zygomorphy has become prevalent. Normally the sepals and petals are in fives or (less frequently) in fours, and separate, but in some families the petals have become lost and the sepals much reduced or also lost. In the earlier families the stamens are very numerous, but in several directions of evolution the number has been reduced to double or equal to that of the petals or sepals. In the less advanced forms the simple pistils are numerous; in one direction of evolution the number is reduced to one, in another direction the reduced number of pistils unites to a compound pistil. Perigyny is present in the lower members of the order, epigyny in some of the higher members. In one group of families the seeds lack endosperm, in other it is abundant. It is only by the presence of so many forms that are intermediate in their characters that these very diverse plants are united into one order. The species number over 14,000 and represent 20 to 25 families. The Strawberry (Fragaria, Fig. 50) represents one of the most primitive groups of the order, being in its flower structure very close to plants of the order Ranales. Other plants are the Rose (Rosa), Apple (Malus), Plum (Prunus), Acacia, Bean (Phaseolus), Clover (Trifolium), Currant (Ribes), Witch Hazel (Hamamelis), etc.

Order 106. *Myrtales.* Trees, shrubs and herbs with opposite or less often alternate leaves. Flowers regular with sepals and petals separate, stamens mostly many or reduced two to four times as many as the petals, rarely just as many or fewer. Pistil compound, of two to many united carpels, with as many locules, or with one locule. Ovules mostly numerous, sometimes reduced to one; seeds with or without endosperm. Pistils surrounded but free from the deep axis-cup in one family, in the remainder enclosed by and grown fast to the axis-cup (ovary inferior). In this order we find a progression from perigyny to epigyny, from many stamens to few stamens, and from possession of petals to apetaly in a few families. Furthermore, several of the 15 families are strict parasites and leafless. Among the latter should be mentioned the East Indian Rafflesia which grows inside the tissues of the woody host as long threads of cells, for all the world like a fungus, forming its flower buds beneath the bark of the host and finally bursting out to form an immense flower, in one species over a yard in diameter. The order contains nearly 7,500 species. The Myrtle family contains many trees of economic importance such as the Blue Gum (Eucalyptus), Allspice (Pimenta), Clove (Eugenia). In another family we find the Pomegranate (Punica). In this order, too, belong the Evening Primrose (Oenothera), Mangrove (Rhizophora), Brazil-nut (Bertholletia), etc.

Order 107. *Loasales.* Mostly herbs, rarely shrubs or trees, with alternate (only rarely op-

posite) leaves; frequently climbing vines. Flowers regular or in one family zygomorphic, with separate sepals and petals, usually in fives or fours. Stamens numerous or equal to or twice as many as the petals, sometimes fewer. Pistil inferior, composed of three or sometimes more, united pistils; with one or sometimes several locules. Seeds usually many, mostly without endosperm. The plants of this order tend to be more fleshy on the whole than in the preceding one, and the ovules are more prevailingly parietal. Both orders apparently have about the same origin and develop parallelly. About 1,400 species in five families. The Gourd family, with Muskmelon and Cucumber (Cucumis), Watermelons (Citrullus), Squash and Pumpkin (Cucurbita), etc., and the Begonia family are perhaps the most familiar representatives of this order.

Order 108. *Cactales.* This order appears to have arisen from the preceding one. The plants are herbaceous and very fleshy, in a few cases with leaves, but mostly leafless. The fleshy, green stem is modified in very remarkable ways and is usually spiny. The flowers are regular or nearly so, with numerous sepals, petals and stamens. The pistil is inferior, of four to eight united carpels, with the numerous ovules parietal. Endosperm is scanty or lacking. The single family contains nearly 1,200 species. These are mostly found in warm parts of the New World, frequently in exceedingly dry situations. The Giant Cactus of Arizona (Carnegiea) attains a height of over 60 feet, while the little Purple Cactus (Coryphantha) from Colorado to Alberta is only one to five inches in height.

Order 109. *Celastrales.* Trees and shrubs, rarely herbs, with opposite or alternate leaves. Flowers small, regular, with separate sepals and petals (the latter wanting in some families), which are usually in fives (or fours). Stamens as many as the sepals, rarely twice as many. Axis of the flower expanded into a more or less glandular, turgid disc, or ring, which partially surrounds the pistil and is grown fast to it in the further developed families. Pistil compound, of two to six (rarely more) united carpels with as many locules, or the locule, only one in certain families. Ovules few: seeds with or without endosperm. This order apparently arose from some of the Rosales in which the axis-cup was shallow and in which epigyny had not yet been developed. However, the reduction in number of stamens had been established and the pistils were compound. Some of the 24 families are included here very doubtfully. In three families the plants are true parasites and in another many species are at least partially so. Belonging to this order are the Grape (Vitis), Holly (Ilex), Sandalwood (Santalum), Mistletoe (Viscum and Phoradendron) and many other plants of economic interest.

Order 110. *Sapindales.* Trees and shrubs (very rarely herbs), with alternate or opposite leaves. Flowers small (with few exceptions), regular (occasionally zygomorphic), sepals and petals separate, from 3 to 10 in number, usually four or five, petals often wanting. Stamens as many as the sepals, rarely twice as many. Axis developing a more or less pronounced disc which is grown fast to the compound pistil in the higher families but free from it in the lower ones. Carpels one or two to five, mostly two or three; pistil with one or several locules; ovules one or two in each locule; seeds without endosperm. This order probably arose from somewhere in the preceding order from which it differs in the mostly smaller number of ovules and carpels, and in the very strongly marked tendency to apetaly. The 15 families contain nearly 3,000 species of plants, of which the following may be mentioned: Maple (Acer), Sumac (Rhus), Mango (Mangifera), Walnut (Juglans), Birch (Betula), Oak (Quercus).

Order 111. *Ammiales.* Trees or shrubs or herbs with alternate or opposite leaves which are very frequently compound. Flowers regular, small, pentamerous or tetramerous; calyx of small sepals, sometimes reduced to a mere border. Petals (rarely wanting) small, separate. Stamens as many as the petals and alternating with them. Compound pistil inferior, of two (rarely three or more) united carpels with a single ovule in each locule. Seeds with endosperm. The flowers are usually borne in large numbers in umbels or small heads, often with the marginal flowers larger and showy. This order of three closely related families and over 2,800 species probably arose from some of the higher Celastrales. In the *Araliaceæ* we find the English Ivy (Hedera) and Ginseng (Panax); in the *Cornaceæ* we find the Dogwood (Cornus); and in the *Ammiaceæ* Celery (Apium), Carrot (Daucus), Fennel (Fœniculum), Parsnip (Pastinaca), etc.

Order 112. *Rubiales.* Trees, shrubs and herbs with opposite leaves which are entire or more or less dissected. Flowers medium-sized to small, regular or sometimes more or less zygomophic, single or more often in clusters of various types, including umbels and heads. Sepals and petals in fives or fours; sepals often small. Petals united into a tube or merely at their bases. Stamens separate, as many as the petals and alternating with them. Pistil inferior, of two to three, sometimes more united carpels, and one to many ovules in each locule, or in one family the locule single with one pendent ovule. Seeds mostly with endosperm. This order of about 5,100 species and five families shows kinship to the preceding order from which it differs chiefly in the united petals. Coffee (Coffea), Elder (Sambucus), Honeysuckle (Lonicera), Teasel (Dipsacus), etc., are members of this order.

Order 113. *Campanulales.* Trees and shrubs, more often herbs, with mostly alternate, undivided leaves. Flowers mostly showy and moderately large, regular or markedly zygomorphic, with sepals and petals mostly in fives. Sepals separate or partly united; petals united into a wheel-shaped or more often more or less bell-shaped corolla which is sometimes two-lipped. Stamens as many as the petals and alternating with them or fewer; united by the anthers or by the filaments or if not united at least in many cases with the anthers closely crowded around the style. Pistils compound, of two to five united carpels, mostly with as many locules as carpels and many ovules in each, in one family with one locule and a single pendent ovule. Pistil inferior, sometimes completely, sometimes only partially. Seeds mostly with endosperm. This order differs from the foregoing one in the prevalence of alternate leaves, in the tendency for the stamens to be

more or less united, and in the greater inclination toward herbaceousness. The two orders are closely related and probably have a common origin. Five or six families are recognized, containing in all toward 1,600 species. The Bellflowers (Campanula) and Lobelia are among the best-known members of this order.

Order 114. *Asterales.* Trees and shrubs or most often herbs with alternate or opposite leaves and great variety of stem structure. Flowers united into heads with the marginal flowers sometimes modified into showy structures ("rays"). Flowers regular or zygomorphic. Sepals very various, e.g., united to a low ridge, separate, chaffy scales, numerous small teeth, or long simple or feathery threads (as in thistle down). Petals five (very rarely four), united into a tube and regularly or irregularly lobed above or the tube split down on one side. Stamens five, attached at the base of the corolla tube, with separate filaments, but with united anthers. Pistil inferior, with one locule and one ascending ovule, bicarpellary. Seed without endosperm. An immense order of over 14,000 species, formerly regarded as a single family, later as constituting three families, but here regarded as representing 14 (the tribes of other authors). This order is regarded as the culmination of the evolutionary development of the Phylum Anthophyta. Among its members may be mentioned the Sunflower (Helianthus), Compass Plant (Silphium, Fig. 51), Goldenrod (Solidago), Thistle (Cirsium), Lettuce (Lactuca), etc.

Class 33. *Monocotyledoneæ.* The monocotyledons are mostly herbaceous plants, rarely trees, without true wood and without the power to increase in thickness (secondary thickening). The vascular bundles are scattered in the stem, not equidistant from the centre. The leaves are mostly scattered along the stem, rarely whorled and only exceptionally opposite. They are long and narrow and parallel-veined, or if broad usually have a midrib, with the lateral veins parallel. The parts of the flowers (sepals, petals, stamens and carpels) are mostly in three's. The seed leaf (cotyledon) is single (apparently through the failure of one of the two that start to form to continue its development). The evidence drawn from structure and from the development of the embryo makes it seem probable that this class arose from some of the herbaceous members of the preceding class (*Dicotyledoneæ*), almost certainly from Order Ranales, close to the Family Ranunculaceæ. Indeed, that group and its near relatives sometimes show a suppression of one cotyledon, a scattered arrangement of vascular bundles which even may lack the power of secondary thickening, and a trimerous arrangement of the parts of the flower. Furthermore, the members of what seems to be the most primitive order of the Monocotyledoneæ, the Alismatales, frequently possess net-veined leaves, and in seedlings of many members of this class traces are found of secondary thickening in the vascular bundles. The eight orders comprise nearly 24,000 species.

Order 115. *Alismatales.* Herbaceous, in one family shrubby or tree-like. Usually in wet soil or aquatic. Pistils simple, mostly more than one, superior to all other parts of the flower, which are also not united to each other. In some of the nine families both petals and sepals are present, in others these are lacking or represented by scales or bristles. Of the 400 species that make up the nine families some are marine; almost the only flowering plants that grow in the ocean. The Water Plantain (Alisma, Fig. 45) is world-wide in its distribution as are some of the Pondweeds (Potamogeton).

Order 116. *Liliales.* The Lilies. The plants of this order are only exceptionally aquatic or marsh inhabitants. They are herbaceous with a few exceptions. The pistil is compound, consisting of (usually) three united carpels. The stamens are in two (sometimes, by suppression of one whorl, one) whorls of three each and the petals and sepals are well developed and often alike. The flowers are radially symmetrical or nearly so. The pistils are attached to the flower axis above all the other parts (pistil superior). The flowers are mostly showy and borne singly or in spikes or various other types of inflorescence, rarely closely crowded. Here are to be found many of the most beautiful flowering plants such as the Lilies proper (Lilium, Fig. 46), Lily of the Valley (Convallaria), Crown Imperial (Fritillaria), Tulips (Tulipa), Mariposa Lilies (Calochortus), Spring Lilies (Erythronium), Hyacinths (Hyacinthus), Day Lilies (Hemerocallis), etc. There are 12 or 13 families and nearly 3,400 species.

Order 117. *Arales.* The Aroids. These have a flower structure derived from that of the Liliales. The pistil is superior and typically tricarpellary, each carpel usually with two or more ovules. The petals and sepals are reduced to small scales or are entirely wanting. The flowers are perfect (stamens and pistils in the same flower) or the stamens and pistils are in separate flowers, usually then not far distant. The flowers are crowded on

rather thick, fleshy spikes which are frequently surrounded and overtopped by a large bract (spathe). In a few cases this spike is reduced to a short axis with only one or two flowers. The plants are mostly large; in some cases being palm-like and somewhat woody, but in most cases herbaceous and upright or climbing. The leaves are large and often net-veined, and entire or lobed or compound. In one family (*Lemnaceæ*, the Duckweeds) the leaves are lacking and the small floating stem is flattened and thallus-like, bearing only one or two flowers at the edge. The 1,100 plants of

this order make up three families which are mostly inhabitants of the warmer regions of the world. In North America the family *Araceæ* is represented by the Jack-in-the-Pulpit (Arisæma), Sweet Flag (Acorus), Skunk Cabbage (Spathyema), etc., while in cultivation we find the Calla Lily (Richardia, Fig. 52) and the Elephant's Ear and Taro (Colocasia), etc. The third family (*Cyclanthaceæ*) consists entirely of tropical forms of which only a few are grown in greenhouses in the temperate regions.

Order 118. *Arecales.* The Palms (Fig. 53) are nearly all shrubs or trees, often 50 to 100 feet in height, but without true secondary thickening. Their stems bear a crown of pinnate or palmate leaves at their summits, and among them are the axial (rarely terminal), usually much-branched inflorescences along whose branches the flowers are attached. The inflorescence has one or more large bracts that enclose it when young. The flowers are of the Lily plan, consisting of a superior, tricarpellary, compound pistil producing from one to three seeds, and two whorls of three stamens each and three rather small petals and sepals respectively. The petals and sepals are lacking in some palms and in many of the tribes the stamens and pistils are in separate flowers. The single family (*Arecaceæ* divided by some authors, perhaps with right, into five or more families) includes more than 1,100 species, all natives of warm climates. Among these are the Coconut Palm (*Cocos nucifera*), "The most useful plant in the world," the Date Palm (*Phœnix dactylifera,* Fig. 53), the Palmetto (Inodes palmetto), etc.

Order 119. *Poales.* The plants of this order are grass-like plants (with the exception of the bamboos, herbaceous), with slender stems and simple, usually narrow leaves. The superior, compound pistil is tricarpellary or bicarpellary (rarely more than tricarpellary), with one ovule to each carpel, or where the pistil has but one locule only one ovule in the pistil. The perianth is reduced to small scales or bristles. The inconspicuous small flowers are accompanied with chaffy bracts. The seeds possess abundant endosperm. Of the five families in this order the Sedges (*Cyperaceæ,* about 3,000 species) and Grasses (*Poaceæ,* about 3,500 species) are the most important. These two families form the chief food for the vast numbers of cattle and wild herbivorous animals that live on prairies and in open forests. The former may be distinguished by the fact that the leaves are three-ranked with their sheaths closed to form a tube while in the grasses they are two-ranked with the sheaths split down one side. In the sedges the embryo is embedded in the endosperm; it lies at one side of it in the grasses. The chief sedges of the temperate regions of North America are very numerous species of Carex, of Cyperus, of Scirpus (Bulrush), etc., while the vast number of grasses include Timothy (Phleum), Red Top (Agrostis), Orchard Grass (Dactylis), Brome Grass (Bromus, Fig. 54), and such cereals as Wheat (Triticum), Rye (Secale), Oats (Avena), Barley (Hordeum), Maize (Zea), Rice (Oryza), etc. The Bamboos (Bambusa and Phyllostachys) are large perennial woody grasses of the warmer regions of the world where they often attain tree-like dimensions.

Order 120. *Hydrocharitales.* The plants here included are all aquatic and mostly submerged. They are found in fresh and salt water. Their compound pistils are formed of three or more united carpels and are interior (i.e., the portion of the flower axis on which the petals and sepals are borne has grown up around the pistil, growing fast to it so that the petals and sepals seem to rise from the upper part of the pistil). They have but one cavity with the mostly numerous ovules parietal. The flowers are of separate sexes, or in some cases perfect. The stamens are in one to several whorls of three. The seeds contain no endosperm. The relationship of the order is uncertain, but it seems possible that they are to be considered as derived from the Alismatales or from the Liliales not far from the point where they arose from the Alismatales. The 50 or more species of the order are placed by some authors in one, by others in two families. Eel-grass (Vallisneria, Fig. 55) and Waterweed (Philotria) are common plants of this order. The latter has become a pest in streams in Europe into which it was introduced from its native home, America, filling them up and even impeding navigation.

FIG. 56.— Iris plants in blossom; greatly reduced.
FIG. 57.— An epiphytic Orchid (Gongora), with pendent flower clusters; greatly reduced.

Order 121. *Iridales.* Herbaceous plants, sometimes of large size, often vines. Flowers radially symmetical or nearly so, with complete trimerous whorls of sepals, petals, stamens and carpels. Stamens in two whorls or the inner or outer whorl lacking. Pistils inferior. These plants are very closely related to the Liliales from which they were undoubtedly derived. The chief difference is the inferior pistil as compared with the superior pistil of that order. About six families include the 1,850 species of this order. Among these may be mentioned the Irises (Iris, Fig. 56), the true Yams (Dioscorea), Amaryllis, Gladiolus, Narcissus, etc.

Order 122. *Zingiberales.* The plants of this order are, like those of the foregoing one, herbaceous, in the case of the bananas being of tree-like dimensions. The flowers are somewhat to exceedingly irregular, either by their dorsiventral symmetry or by total lack of symmetry. The whorls of stamens are usually incomplete, certain members being lacking or replaced by petaloid "staminodia." The pistil is inferior and consists of three united carpels with one to many seeds in each. This order is closely related to the foregoing one from

which it differs chiefly by its zygomorphous or asymmetrical flowers with incomplete whorls of stamens. The Banana (Musa), Ginger (Zingiber), Canna, etc., are well-known representatives of the group which contains about 550 species in four families.

Order 123. *Orchidales.* The two families generally placed in this order are not with any certainty to be placed together. Possibly the one (*Burmanniaceæ*) should be placed with the Iridales. The two agree, however, in the inferior, tricarpellary pistil with very numerous, minute seeds with no or very little endosperm. In the one family (of about 60 species) the flowers of some species are radially symmetrical, of other species zygomorphic, the latter being the case throughout the other family (*Orchidaceæ*). In the latter family, three, four or five stamens are suppressed, while in the former both whorls or only one whorl may be present. The plants are all herbaceous. The Orchids (Fig. 57) number upwards of 7,500 species and are found from the cooler temperate zones to the tropics where they reach their greatest development. They are terrestrial or epiphytic, green or in a few cases lacking chlorophyll and then gaining their food from decaying organic matter in the soil. None are parasites. The flowers are strongly zygomorphous, with the one or two (rarely three) stamens grown fast to the pistil. They show the most remarkable adaptation to fertilization by insects. Although grown largely for the beauty of their usually long-persisting flowers, e.g.— Cattleya, Catasetum, Dendrobium, etc., the only orchid widely cultivated for other purposes is Vanilla, a climbing vine with thick, green stem and flat leaves, whose long slender pods are the "Vanilla beans" of trade. Among the commoner native orchids of temperate North America may be mentioned the Lady's Slipper (Cypripedium), Orchis, Pagonia, etc.

CHARLES E. BESSEY,
Late Professor of Botany, The University of Nebraska,
Revised by ERNST A. BESSEY,
Professor of Botany, Michigan State College.

PLANTS, Diseases of. Diseases in plants have existed as long as plants themselves — ages before the advent of man. Civilization and agriculture have usually developed together in all parts of the earth and it is not strange that anything that troubled or destroyed an important food plant should be observed and the cause sought. In the earliest historic records as well as in early Greek and Roman times some of the more destructive diseases of plants, like rust and mildew or blight of cereals, were widely known and discussed. A special deity was recognized who ruled these phenomena and to whom sacrifices were offered.

Injury due to animals, especially insects, and to extremes of weather and unfavorable soil conditions were early often associated with their appropriate causes. It was not, however, until the latter part of the 18th and the beginning of the 19th century that the solid foundations of plant pathology were laid by the development of anatomy and physiology. The early works of Unger, 'Die Exantheme der Pflanzen,' etc. (1833); Weigmann, 'Die Krankheiten und Krankhaften Misbildungen der Gewälchse' (1839), and of Meyen, 'Pflanzenpathologie' (1841), mark an important step forward in the embryo science of plant pathology. During this period miscroscopical chemical and physiological work with plants was active. The writers of this period rather overworked unfavorable nutrition as the cause of disease. Maladies that could not be traced to visible external causes were usually held to be due to unsuitable nourishment or the lack of something in the soil. It was not believed that the fungi so often found associated with diseases had any casual relation to them. They were held to be abnormal developments of the diseased cells themselves and not independent organisms. It remained for De Bary to determine the true nature and habits of fungi and bacteria and to demonstrate their causal relation to disease in many cases. His careful work gave a great stimulus to investigation in plant and animal pathology and opened what has proved to be the most important field of the science. His two most important works are 'Untersuchungen über die Brandpilze,' etc. (1853), and 'Morphologie und Physiologie der Pilze,' etc. (1866). Since De Bary the rapid development of the subject is well represented by the works of Hartig (1874–89), Frank (1880–96), Sorauer (1886–88), Marshall Ward (1889–1901). The last work, 'Diseases in Plants,' is one of the most excellent and readable expositions of the subject that has appeared.

Health and Disease Compared.— That there is no defined line between health and disease is generally recognized by pathologists and physiologists. A plant continually varies in response to changes in its environment. There is, however, for each individual and for a given species as a whole a certain accustomed range or power of adaptation to each factor of its environment and to the various combinations of these factors. The process of natural selection operates to perfect this adaptive attuning of the individual and the species as a whole to the conditions under which they live. If these conditions are subject to great extremes of moisture and dryness or heat and cold, the natural or indigenous vegetation will be found, as a rule, equal to the emergency, while an introduced species, if developed under an environment not subject to such extremes, might be seriously injured or destroyed, and if the change is very unusual even the indigenous species may suffer. A moist, warm, cloudy spring may be followed by dry, hot weather and the tender watery growth be so much dried out and checked that it may be deformed and abnormal in shape, structure and size. This variation may be slight or it may be great. If it is slight it may have no appreciable effect on the vigor and growth of the plant. The leaves becomes a little firmer and smaller and more resistant to the hot, dry conditions, while the maturer leaves that cannot adapt themselves to the change turn yellow and fall, cut off by the parent plant. The plant is better for the change and can live under the modified conditions with greater ease and safety.

If the variation is greater the growth of the plant may be decidedly checked, the leaves being small and many more of them shed. In still more extreme cases the tender leaves may be dried up and killed either wholly or in part. According to Hartig, "It is only when the sickly

condition leads to the death of some part of the plant that we may speak of actual disease.» Where a few leaves, unable to adapt themselves to a changed condition, turn yellow and fall, the leaves themselves may be diseased, but the plant as a whole is benefited by their loss by being relieved of sources of uncontrolled drain of its water supply. As the loss of leaves becomes greater, however, we pass from the extremely localized disease to a point where the whole or a considerable part of the plant is weakened, either by the direct loss of food that should be furnished by the leaves to the rest of the plant structure or by the use of reserve food in the reproduction of lost parts. It is evident in such cases that the border line between health and disease is hard to define. The case is not much easier if, instead of variations produced by moisture and temperature, we consider those caused by insects or fungi. A few leaves eaten from a tree by some insect or destroyed by a fungus might have no injurious effect on the tree as a whole and might even be an advantage, but as the number of injured leaves increases the tree is weakened and its life threatened. Slight doses of certain poisons stimulate the cells to more vigorous growth, acting as a tonic, while a little larger dose poisons and destroys the cell. Leaving all questions of consistency of definition, we may practically define as diseased all those conditions of a plant which directly or indirectly endanger its life or prevent normal development under given conditions of environment. Or, as Marshall Ward puts it, «We may define disease as dangerous disturbances in the regularity, or interference with the completeness or range of the molecular activities constituting normal life — that is, health — and it is evident that every degree of transition may be realized between the two extremes.»

Classification of Diseases.— The method of classification adopted is more a matter of convenience than importance. Most writers in plant pathology base their classifications on the causes of disease. Frank, for example, adopts the following outline: (1) Effects of insufficient room or space; (2) Effects of wounds; (3) Diseases due to atmospheric influences; (4) Diseases due to soil influences; (5) Diseases due to the action of injurious substances; (6) Diseases due to injurious plants; (7) Diseases due to injurious animals; (8) Diseases without any noticeable causes.

Hartig discusses diseases of trees according to the following scheme: (1) Diseases induced by Phanerogams; (2) Diseases induced by Cryptogams; (3) Wounds; (4) Diseases due to unfavorable conditions of soil; (5) Diseases due to unfavorable atmospheric conditions. While a classification based on cause is more scientific and more convenient for the pathologist, classifications based on the plant, the part of the plant attacked and the symptoms are the most intelligible and convenient for those who devote themselves to the practical cultivation of plants. According to such an arrangement we should have diseases of roses, carnations, violets, lilies, wheat, corn, oats, rye, apple trees, peaches, plums, maple, alder, birch, etc. Under each head we could subdivide into diseases of roots, stems, leaves, flowers and fruits, and again according to symptoms — decay or loss of parts, swellings, galls, shrinking, cankers, spots, discolorations, etc., finally coming down to the causes. It cannot be too strongly urged that pathologists writing for practical men adopt this latter type of classification at least as a key for the identification of specific diseases, as Hartig has done in his excellent work on the 'Diseases of Trees.' In practice we have in plant pathology, the same as in animal pathology, first carefully to examine, determine and interpret the symptoms (diagnosis), then to find and study the causes (etiology). We are then in a position to determine curative measures (therapeutics) or preventive measures (prophylaxis).

The general survey of the subject of plant pathology as planned in this article is based on the following classification:

I. Constitutional conditions — predisposition and immunity.

II. Diseases without apparent cause.

III. Diseases caused by the non-living environment.

- (*a*) Conditions of soil or substratum.
- (*b*) Atmospheric conditions.
- (*c*) Temperature.
- (*d*) Light.
- (*e*) Electricity.
- (*f*) Shock or jars — mechanical.

IV. Diseases caused by the living environment.

- (*a*) Antagonistic association, crowding, isolation, etc.
- (*b*) Vegetable parasites.
- (*c*) Animal parasites.

Constitutional Conditions — Predisposition and Immunity.—A plant may be likened to a very delicately constructed and complex machine automatically adjustable under certain conditions and capable of running and doing work if properly supplied with energy. The accurate and perfect working of the machine depends first upon the perfection of its construction and adjustment, down to the minutest detail. It comes from the manufacturer with a wheel or screw missing, or the parts incorrectly adjusted or made, it must do its work, if at all, with more or less imperfection, and we may consider that the mechanism has a constitutional difficulty or imperfection. Perhaps a new machine is assembled from parts of old ones so differing from each other that it becomes impossible to produce a perfectly coordinated mechanism. Some of the variations that occur in the constitution and organization of plants during the process of reproduction and development are of the nature of such imperfect construction or adjustment. When these imperfections endanger the life of the plant we have a constitutional disease, or at least a predisposition to disease.

Predisposition to disease may be normal or abnormal. Normal predisposition is where some perfectly normal condition of growth makes the plant liable to injury. Young cereal plants, for example, are liable to infection by smuts, while older plants are quite resistant. When the formation of young, tender growth coincides with the spore dissemination of some fungus or the prevalence of some insect best able to attack growth in such condition, the plant is at this stage normally predisposed to such attack. In the same way there may be normal predisposition to injury by cold, light,

heat, etc., but in no case of this kind could the predisposition be considered in any sense disease. Abnormal predisposition is where some abnormal change takes place in the plant from any cause which lowers its vitality or resistance, and which is in itself a pathological condition. Wounds and mechanical injuries may permit the entrance into the plant of insect or fungous parasites, as is the case with many of the wood rot fungi. Injuries from cold or heat may reduce the normal resistance to parasites. Plants which have been severely chilled during rapid growth, though not to the point of killing or even freezing, are often unable to resume normal growth even under the most favorable conditions. They appear to be partially paralyzed and are in this condition extremely subject to insect and fungous attack. So many predispositions develop as the result of starvation, overfeeding or unbalanced nutrition even before the initiative pathological changes have become chronic.

Genera, species and individuals vary among themselves in liability to disease or resistance to it as they do in other ways. Races resistant or immune to certain unfavorable conditions or parasitic enemies are common in nature, and may develop as the result of natural selection, or more quickly and certainly as the result of artificial selection of a natural tendency. If a natural tendency to resistance is not present in a given species, race or variety, it may be introduced into new generations through the processes of breeding and selection combined. The production of plants for special purposes resistant or immune to certain diseases is proving of immense value to agriculture. On the other hand, both in natural and artificial selection and breeding, non-resistant or sensitive individuals, varieties and races may develop or be developed unusually subject to disease.

Seedless or non-fertile individuals may result from too close fertilization, or where the parents are too distantly related; or if seeds are produced in such cases, the individuals grown from the seeds often lack in vigor or reach an incomplete or imperfect development the same as in animals.

Many species of plants, like the violet, strawberry, lilies and bulbous and tuberous rooted plants in general, are naturally propagated by vegetative offshoots, runners, buds, bulbs, etc., and by seeds. The seed generations under normal conditions are usually the most vigorous and variable. Take, for example, plants from the seeds of *Lilium harrisii* (Bermuda lily), derived from crossing individuals of the same variety, as compared with plants from bulblets of the same individuals propagated for many years by bulb generations, and note the differences. The plants direct from the seed and from the bulbs produced by the seedling generation are relatively much more vigorous than the plants from bulbs distantly removed from a seed generation. The latter are much more sensitive than the former to the attacks of aphides and red mites on the leaves and the bulb mites on the bulbs and roots. The latter are also more sensitive than the former to fungous parasites, and to unfavorable conditions of the non-living environment. The same is true of the cultivated violets, especially the varieties that are propagated from runners and seldom produce seed on account of the doubling of the flowers. Long continued asexual propagation appears in these cases to gradually reduce the power of individual adjustment or adaptation to changes in environment, resulting in decreased vigor and resistance to unfavorable conditions. On the other hand, there are many varieties of plants thus propagated that do not appear to suffer in this way. That it is the cause of predisposition to disease in some cases, and even constitutional derangement, must not be overlooked in the study of ætiology of a disease.

Diseases without Apparent Cause.— Under this head a number of obscure but well-defined diseases are grouped, the ætiology of which is still unknown. Among these are the California vine disease, peach yellows and peach rosette, little peach, some forms of gummosis of the stone fruits, die back of the orange and a score of other diseases, apparently contagious, though the cause has not yet been found.

Variegation.— Formerly variegations were included in this class. These are characterized by the development of white, yellow or colored spots, blotches, segments, stripes or bands in the otherwise apparently normal green leaves. The transition from the diseased to healthy cells is usually sharp and well defined from the youngest to the oldest stages of the leaves or other tissues involved. Any particular cell is subject to the disease only while in a state of active division. It, therefore, never spreads to a cell that has stopped dividing. The diseased cells are usually smaller than healthy cells, and are of much slower growth. The nucleus and protoplasm are more vacuolate, but the most apparent change is in the development of the chloroplast and the chlorophyll. The chloroplasts may be reduced in number and size, and the chlorophyll may be reduced or entirely absent. The change in the diseased cells themselves is often progressive, starting with a reduction of chlorophyll, gradually fading to yellow, then to white as the cell matures. In many cases the disease is transmitted through the seed and is thus hereditary. In others it is propagated only by division of the original plant by buds, cuttings, etc. When a variegated bud or branch is grafted into young, rapidly-growing tissues of a normal or healthy plant of the same variety, branches formed above and below the graft often become variegated, demonstrating that the disease is thus transmissible or infectious. When it once appears in a plant it is very persistent, especially when it has gone to the point of involving the seed generation. Sometimes, however, a plant which has been producing variegated growth suddenly returns to the normal green. While such changes are usually classed as spontaneous variations, they differ in many respects from normal variation. Recent investigations by the writer and others have demonstrated that variegations, including the so-called mosaic diseases, develop as the result of certain disturbances of nutrition of the young dividing bulb cells.

All forms of variegation weaken the tissues involved and make them more subject to insect and fungous attack and more easily injured by cold or high temperature. Besides this the changes are in themselves strictly pathological, and threaten or cause the premature death at least of the parts affected.

Albinism.— When the loss of the green col-

oring matter is complete and apparently spontaneous, not curable by addition of some lacking nutrient, it may be classed with variegations. Other forms of albinism, yellowing or chlorosis are brought about by lack of iron, excess of lime, carbonic acid, lack of light, etc., and will be further discussed when these factors are considered in relation to disease. The cure and prevention of diseases of this class must be based on securing and maintaining a correctly balanced nutrition for the young cells — protecting them from shocks, especially those due to temperature variations. Peach yellows and rosette, California vine disease, die back of the orange and diseases of this type can be controlled only by rooting out the diseased individuals upon the appearance of the first symptoms. At the present time we know no cure for these particular diseases. In many respects they behave like variegation or mosaic diseases.

Diseases Caused by the Non-Living Environment.

From what has been said in previous paragraphs, it is evident that unfavorable physical and chemical conditions of the soil, excessive dryness or moisture of the soil or atmosphere, unfavorable conditions of temperature, light, etc., may cause derangements resulting in temporary or chronic disease. Plants which have become adapted by natural or artificial selection to a certain range and sequence of soil, moisture, temperature and light conditions usually suffer some sort of derangement if exposed to a set of conditions materially different in any particular factor, group of factors or in the relation of these to each other. It is absolutely necessary, therefore, in studying the ætiology of diseases to know the natural or constitutional requirements of the plants and their powers of adaptation. This knowledge can be obtained only by long and intimate acquaintance with the kind of plants in question under varying conditions.

Soil.— In natural conditions it is a matter of general observation that certain varieties of plants thrive best on particular kinds of soil, the same as in particular conditions of light, temperature and moisture. The storage and movement of water in soils and its availability to plants, the solution of soil foods, nitrification, temperature and aëration depends largely upon the structure or physical composition of the soils. Water, food, air and temperature are among the fundamental requirements of vegetation. It is the varying amounts and relations of these factors maintained by a given soil that largely determine whether or not it is *naturally* suited in a given region to a particular class of plants. Where all these conditions are under easy control the kind of soil is a matter of less importance. The work of furnishing and maintaining proper conditions is done by the gardener instead of by the soil in the latter case. It is not profitable, however, to employ soils that require close and constant attention, even where conditions are largely under control. It is the aim of economical production to select a soil for a given crop that, with a minimum of labor expended on the part of the cultivator, produces the desired results. It is evident from these considerations that the conditions of the soil must be considered in connection with all of the other factors of environment, as no one of them ever acts independently and alone in the production of disease. The plant, too, has to be considered. It may be adapted to withstand the variations that take place in a sandy soil in a locality characterized by particular meteorological conditions, while it could not thrive in a clay soil in the same locality. On the other hand, with changed meteorological conditions the same plant might do best in the clay soil.

Root Suffocation.— This is one of the most usual diseased conditions caused by physical conditions of the soil preventing the ready access of atmospheric oxygen or the ventilation of the soil. A very fine sand closely packed, or a clay soil with a crust excludes the air, unless the sand is stirred or the crust broken. Carbon-dioxide accumulates and the oxygen is reduced. The root hairs and feeding roots die for lack of sufficient oxygen for respiration. Growth is checked by starvation due to reduced root action. The tissues become hard and woody. The plant may then die in dry, hot weather by desiccation, or it may simply starve to death. Plants injured in this way, even slightly, often become the prey of insects and fungi, especially of those that attack the roots. This form of suffocation is also often found where the roots of plants have to grow under close pavements or hard packed ground or heavy sod. Another form of root suffocation results from poor drainage or excess of moisture in a soil, thus excluding the oxygen and preventing soil ventilation. The feeding roots die and ferment, not only cutting off the proper absorption of soil food elements but resulting in poisoning the plant by products of fermentation. The leaves rapidly turn yellow and drop, and unless the soil is dried out and aërated the plant soon dies. This latter form of root suffocation is very common among plants grown in pots or tubs. When the natural drainage is stopped up or the plant is over-watered, the soil becomes sour.

The best thing to do in such a case is to repot the plant into fresh soil containing a little lime or wood ashes, first washing off the old soil and trimming off the diseased roots. Good drainage must be furnished and over-watering avoided. It must be clearly understood that the roots of most plants require an abundant supply of oxygen, and that they will suffocate and die if they do not get it.

Poisonous materials in the soil are also often the cause of serious root injury. Illuminating gas leaking from gas mains or pipes and diffusing through the soil in the minutest quantity kills and poisons the roots of all kinds of vegetation. The only thing to do in such cases is to stop the leak and air the soil.

The decomposition of organic matter, especially manures rich in nitrogen, in soils not well supplied with oxygen, results in the formation of products injurious to the roots of plants. Injurious acids are often set free from their combinations in the soil by the action of plant roots, bacteria and fungi and by chemical changes brought about by the use of certain fertilizers, like the acid of superphosphates. In all those cases a liberal addition of lime to the soil acts as a cure to the injured plant and corrects the acid condition.

Alkali Soils.— In some cases, on the other hand, there is too much lime or other alkaline material such as carbonate of soda, etc., in the

soil. The root hairs and feeding roots are killed by a sudden rise of a soluble alkali, or they may die a slow death if there is too much lime. It is a curious fact that a liberal addition of gypsum tends greatly to reduce the injury in both these cases and to raise the limit of endurance of most crops of alkali. Where alkalis cannot be washed out of soils through proper drainage, much can be done by breeding and selecting varieties of plants better adapted to such conditions. Great progress has already been made in this direction with alfalfa, sugar beets, cereals, date palms, etc.

Soil Nutrients.— Every green plant requires for its healthy development, besides water, oxygen and the CO_2 of the air, a certain proportion of nitrogen in the form of nitrates or ammonia, a salt of potassium and of phosphoric acid, available calcium and magnesium in about equal proportion, sulphur and a trace of iron and chlorine. If these are not available to the plant in the right form or ratio, or if any of them is too greatly in excess or lacking, a diseased condition of the plants in such soils quickly develops.

Nitrogen.— Lack of nitrogen in available form causes a proportionately diminished vegetative growth, light green or yellowish leaves, even where there is abundant moisture and other nutrient materials. An excess of nitrogenous fertilizer, on the other hand, causes various pathological derangements. Abnormal vegetative growth at the expense of flowers and fruit thus inducing temporary sterility is one of the commonest results of a food containing too much nitrogen in comparison with potassium and phosphoric acid. The tissues in such cases are likely to be soft and watery, easily injured by unfavorable temperature or moisture conditions as well as by insect and fungous parasites.

Tissue degeneration is in many cases the result of overfeeding with nitrogenous fertilizer. This appears to be one of the commonest causes of " die back " or gummy degeneration of the orange. Peaches and plums also suffer from a similar malady from the same cause. Large gum pockets develop in the wood as a result of the degeneration of the cells. The movement of water and food materials in the plant is greatly interfered with. The wood does not mature properly and as a result winter kills, or it is destroyed by insect and fungous parasites.

Phosphoric acid is an important constituent of every living cell, entering largely into the composition of the nucleus. Its reduction below the cell requirements is followed by a cessation of cell division and growth and in green cells by disorganization of the chlorophyll which first becomes reddish, then yellow. These latter changes take place first in the maturer leaves, then in the younger parts. An application of phosphates or superphosphates usually promptly corrects these pathological conditions.

Potassium also is required in considerable quantity by all plants. One of the first signs in a plant of a lack of available potassium is a decided cessation of growth without other apparent cause of trouble. During the early stages of potash starvation the plants often retain their normal green color. In later stages very little starch or sugar is made and almost no protein or nitrogenous matter. Unless the missing element is supplied the plants finally become yellow and slowly die. Potassium hastens and perfects the maturing of plants, especially the ripening of the wood of perennial plants, making them less liable to winter injury.

Calcium.— Lack of this element in plant nutrition is first indicated by a more or less marked yellowing of the young leaves due to a reduction in number and size of the chloroplasts though the chlorophyll itself may be normal. The starch made by the chloroplasts is converted with difficulty into sugar. This retardation is probably due to the fact that in calcium starvation the production of the starch transforming enzyme (diastase) is greatly reduced.

Magnesium.— While this element does not appear to be of such fundamental importance to the vegetable cell it is nevertheless absolutely required, especially during the periods of flowering and fruiting. A very small amount may often suffice to meet the requirements of growth up to the flowering period, but at this time a decided lack of magnesium results in the failure to set fruit or its failure to mature. With a more decided lack normal vegetation soon ceases, proleptic shoots develop with shortened stems, small, distorted, yellowish leaves crowded together in rosettes somewhat resembling potash starvation except in color.

It appears to be necessary that magnesium and calcium always be associated in plant cells except in some of the lower classes of plants. The ratio of one part of magnesium to three of calcium is the most favorable in many cases though this is quite variable for different species. In a large number of cases an excess of magnesium over calcium results in greatly retarded growth and an early death of the cells.

Both magnesium and calcium oxides (lime) play a secondary part in the soil by combining with the acids set free by root action, fermentations and other biological and chemical processes. If these were not at once combined the root hairs and feeding roots would be injured or killed and the plant would suffer from general starvation if not actual poisoning.

Sulphur.— This element usually absorbed by plants in the form of sulphates is one of the absolute requirements of all organisms. It enters into the structure of protoplasm and the more highly organized nitrogenous foods, proteids, required as the direct food of growing cells. Its abnormal reduction results in the cessation of proteid manufacture and consequently causes proteid starvation. Growth ceases and death follows unless the element in some available form is supplied.

Other elements and compounds are often important to the plant though not required. Silica for example is found very commonly deposited in the cell walls of plants, especially in the epodermal cells of cereals and grasses. Its presence stiffens the stems and leaves and in a measure protects them from biting and sucking insects and other small animals. Aside from decreased resistance to such attack a plant grows as well without silica as with it.

Chlorine.— This element in very small quantity appears to be necessary to the vigorous growth of plants, especially during the formation of flowers and fruit. In excess it is usually injurious except to plants adapted to soils rich in chlorides, such as sugar beets, asparagus, celery, etc. It is an interesting fact that sugar beets and celery are rendered much more resistant to spot diseases caused by Cercospora when well supplied with sodium chloride, than without it. Why this is so has not been determined.

Iron.— A small amount of this element is necessary to the formation of chlorophyll. An insufficient amount of iron is indicated very quickly by the formation of chlorotic or white leaves which become green on the addition to the soil of a soluble iron salt, such as iron sulphate. Often the failure of a plant to obtain iron is due to the death of the root hairs and feeding roots from various causes, alkali or acid, excessive moisture or dryness, insect or fungous attack, etc. In such cases, however, there are indications of general starvation as well as of lack of iron, and the diseased condition can be cured only by removing the cause of the death of the roots.

Atmospheric Conditions.— The close coordination between the conditions affecting the plant in the soil and atmosphere is at once apparent. In most of our ordinary plants, water, with various materials in solution, is absorbed by the roots from the soil and passes up through the stem to the leaves and other parts above ground. From these there is a continual loss of moisture, regulated in part by the plant, but depending largely upon whether or not conditions of the atmosphere, light, etc., favor evaporation, or transpiration as it is more correctly termed where living plants are under consideration.

Moisture Variation.— Plants growing in soil and air uniformly moist have smaller root systems and a larger total leaf surface than they would have if grown under constantly varying conditions of soil and atmospheric moisture. A plant reared in a moist greenhouse will gradually shed its older leaves if the air is allowed to become too dry or the plant is removed to an ordinary dwelling-room. The new leaves that develop under such circumstances are adapted to the drier air and are better able to retain the water furnished by the roots. If, however, the change from moist to dry is too sudden, the defoliation will be excessive and the new growth may develop very slowly and be poorly nourished. In the case of house plants there is almost a universal tendency to over-water the plant at such times. This brings on suffocation and death of the root hairs and feeding roots, and ends in death of the plant. Instead of watering under such conditions the soil should be allowed to become

comparatively dry until renewed growth of leaves create a demand for water from the roots.

Plants which have been growing for a considerable period with a comparatively small water supply develop a large number of root hairs and firmer and smaller leaves adapted to reduce transpiration to its lowest terms. If a cloudy, wet period suddenly follows, or the plants are over-watered, they become gorged with water. The more plastic tissues start into growth, with the result that the leaves often become distorted, wrinkled, curled or twisted. If there is a continued excess of moisture many of the root hairs and finer roots may die, and symptoms of root suffocation develop, the leaves become spotted with yellow and finally drop off.

Œdema is a pathological condition characterized by the formation of water blisters or warts on the stems or along the vascular bundles of leaves over-gorged with water. This diseased condition often develops in plants growing in moist situations, especially under conditions where the soil is likely to be warmer than the air, thus favoring absorption of water by the roots, but not favoring transpiration through the leaves. The disease often develops, also, in extended periods of moist, warm, cloudy weather.

Burning or Scalding.— The growth that plants make under cloudy, moist conditions is often watery and soft, an easy prey for parasitic fungi and likely to dry out, wilt and die easily if suddenly exposed to clear, hot weather. Such "burning" or "scalding" of the edges and tips of leaves is very common in the spring, when moist, cloudy periods are suddenly followed by clear, hot days.

Wind often causes injury by whipping and tearing the leaves or breaking limbs. In the latter case injuries are produced which predispose the plant (especially trees and shrubs) to attack by insects or fungi. Wherever possible all such injured parts should be cut out to uninjured tissue and protected by antiseptic washes or grafting wax. Dry, hot winds coming early in the summer often cause the death of tender foliage by desiccation.

Injurious Gases.— Slight traces of illuminating gas escaping in rooms or greenhouses, or the slightest trace of sulphurous fumes from burning coal from furnaces or stoves, is extremely injurious to vegetation. The presence of these gases in the atmosphere causes the gradual yellowing, browning and finally the death of leaves, especially the tips and edges. Although the soil, temperature and light conditions may be the most favorable, the plants gradually die where they are more or less constantly exposed to a trace of these gases. In the neighborhood of factories or large cities vegetation is often injured, as described, by these and other poisonous gases. In some cases the amount of poisonous gas thrown into the air with the smoke from certain factories is so great that vegetation of all kinds is unable to thrive in the neighborhood. The injury extends often several miles from the factory in the direction of the prevailing wind.

Temperature.— Many predispositions to disease, as well as specific pathological conditions, are produced in plants as the result of unfavorable temperature conditions. As a rule, when growth is taking place and the cells contain much water, vegetation is most sensitive to heat and cold. When growth has ceased and the tisses are mature or in a resting or dormant condition and contain much less water, they are least sensitive to heat and cold. The temperature range for any individual during growth, and even in the dormant or resting condition, varies for different individuals, varieties and species. These temperature ranges have become more or less fixed within certain limits for different individuals and species through the influence of the temperature factor in the environment under which the species or individuals have developed. Thus, plants adapted to long growing seasons of the South will not thrive in the shorter, colder season of the North. On the other hand, many plants adapted to Northern conditions do not thrive in the South. When an individual or a species becomes adjusted or accustomed to the conditions and changes of a particular environment it may be unable wholly or in part to adjust its life processes to an unusual change in any factor or group of factors or the relation of these to each other. The orange, lemon, lime and numerous other subtropical fruits, for example, do not have a well-defined resting or dormant period like the apple, pear, peach, etc., in the North. They would, therefore, be quickly killed if exposed to severe frosts.

Certain varieties of peaches and plums which survive Northern winters without injury, when planted in the South often winter-kill. Extended warm spells in the latter part of winter, and the warming effects of the sun on the south and southwest sides of the trunk start the activity of the cambium, which is subsequently injured or killed by freezing, the same as are young buds pushing out too early in the spring under the influence of warm days and when caught by the late frosts.

Varieties that start into growth readily under such conditions may be completely winter-killed if the conditions are such as to stimulate a general premature activity. If only the tissues warmed by the direct action of the sun are involved, patches of various sizes may be killed. These usually start near the surface of the ground on the southwest side of the tree and extend up the trunk to the limbs, varying in width from a few inches to the whole south and southwest side.

Winter Sun Scald.— This term is usually applied to cases like those just described where smaller areas on the south or southwest side of trees are killed during winter by the successive warming and freezing of the tissues. This form of injury is common in the North and West. Considerable protection may be afforded in all such cases by coating the tree with whitewash or protecting it from the direct action of the sun in some way.

Winter Desiccation.— Evergreen trees and shrubs are often killed or greatly injured during periods of bright warm weather in the winter by rapid evaporation of water from the leaves while the ground and roots are frozen and unable to replace what is lost.

Another form of winter desiccation is through the direct action of freezing, where, by intense cold, the water is drawn so completely from the protoplasm into the cell walls or intercellular spaces in the formation of ice crys-

tals that the cells are unable to reabsorb water on thawing. This effect of freezing is similar in many respects to that of drouth. Water is withdrawn from the protoplasm to a greater or less extent, according to the duration and severity of the cold and the retaining power of the protoplasm. If the withdrawal has not been too great and thawing process is slow so that the cells can gradually reabsorb what was given up in freezing, the plant may suffer no harm. If on the other hand, the tissues are thawed rapidly, the air is driven out of the intercellular spaces and the cells may die for want of oxygen or the water may be lost by evaporation before it can be reabsorbed. Frozen plants should, therefore, be thawed slowly and protected from evaporation by sprinkling with cold water or shading. While most cases of injury from freezing are due to the conditions just described, there is another class of cases where the injury is apparently due to structural and chemical changes in the protoplasm induced by the cold.

Cold Rigor.—As already pointed out, the sensitiveness of protoplasm of various plants and at various stages of growth differs remarkably, but in all cases during vegetative activity there is a point either a little above or below the freezing point of water where protoplasmic movement and growth cease without the cells being necessarily frozen or killed. This condition is known as cold rigor and is often taken advantage of by florists and gardeners in holding their flowers or fruits temporarily in some particular stage of development for a particular market period. Uusually when the temperature is raised the growth continues normally, but occasionally, if the temperature is a little too low and long continued, the plant fails to respond again to a higher temperature and is found to be in a state of permanent rigor or paralysis; though the plant does not die, it makes little or no growth.

Mechanical Separation of Cells.— In many parenchymatous tissues, leaves, bark, parenchyma, fruits, etc., which can stand considerable freezing without injury to the protoplasm, there is more or less rupture of the cells from each other by the formation of ice in the cell walls or intercellular spaces. In some cases the epidermal cells are almost completely separated from the rest of the tissue. In other cases, as in apples and bark parenchyma, the individual cells may, in extreme cases, be separated and form a powdery mass. If the separation is complete the cells die after a time. In any case, even a partial separation and breaking of the protoplasmic connections between the cells interferes with normal development, and may cause the premature death of the whole or parts of the plant by interfering with the movement of food materials, etc.

Frost-cracks.— These usually occur as the result of rapid freezing and shrinking of the outer tissues of trees, especially while the inner tissues are relatively warm. After the cold period is over and warmer weather comes such cracks close up.

Frost Canker.— This name is applied to wounds that are prevented from healing through the action of late frost in killing the callus rings as they develop. The killing of roots and the lifting of plants from the soil by freezing are familiar phenomena to all gardeners, but further consideration of this subject cannot be undertaken here.

Scorching or Burning.— Sometimes in hot, dry weather smooth-barked trees and shrubs may have portions of their tissue exposed to strong sunlight actually killed by the high temperature. In light-colored, sandy soils the reflection of heat from the sand often kills the lower leaves of low-growing trees, shrubs and especially of herbaceous plants. The reflection of sun heat from the south or west side of buildings, etc., may also cause similar injury. The direct injury in such cases is often, however, confused with the effects of excessive transpiration. The burning effect of hot, dry winds is largely due to the excessive transpiration they induce. The burning is especially severe when there is an insufficiency of soil moisture as the result of drouth or lack of proper cultivation.

Sudden Variations of Temperature.—As already indicated, the injury resulting from changes of temperature above the maximum or below the minimum for a species or individual depends in large measure upon the rapidity of the change. If the change is slow, even the individual plant may adjust its vital processes to temperatures which would have resulted in death had they been sudden. Some of the algæ, for example, live in hot springs at a temperature of 93° C., while the original stock from which these forms were derived lives in water rarely exceeding 40° C. A transfer of individuals from 40° to 93° would result in almost instant death, while by slow, gradual change they could be accustomed to this extreme temperature. For flowering plants (Phanerogams) the possible maximum is much lower, 50° being the extreme limit, while the average limit is from 37° to 46°.

Sudden variations well within the fatal limits, however, are productive of pathological changes. A rose, tomato, violet or almost any other plant grown at a cool temperature (8° to 15° C.), all other conditions remaining the same and then suddenly exposed to 24° to 27° C., will turn yellowish, become weak and spindling and very sensitive to insects and parasitic diseases. The same plants, started at 24° to 27° and growing normally at that temperature, if suddenly dropped to 15° or 8° become yellowish and weak and very sensitive to parasite enemies. In either case the change from one temperature to the other could be made without serious injury if made gradually and slowly. For a general discussion of this subject with references to literature, consult Davenport's 'Experimental Morphology.'

Resting or Dormant Period.—A resting or dormant period is more or less well defined in many perennial plants. In northern and temperate latitudes this period coincides with cold weather and has developed in response to this constantly recurring seasonal change. In other cases in hot climates a partial rest may occur during the dry season. In many cases this period of rest has come to be a necessity to the normal and healthy development of the plant. Detmer and Müller-Thurgau have shown in the case of potato tubers and many dormant buds that in the fall and early winter the tissues contain only enough sugar to meet the demands of respiration of the dormant cells, not enough to stimulate growth. Müller-Thurgau has dem-

1-6. Brand-fungi (Ustilagineae) of Oats and Wheat, with Spores. 7-10. Potato Rot. 11-15. Rusts, showing effects on leaves. 16. Leaf affected by Hymenomycetous Fungi (Oidium). 17. Oidium-Growth. 18-23. Ergot-fungus, showing development and effects.

onstrated that exposure of tubers dug in August to 0° C. for a few weeks causes an accumulation of sugar sufficient to start normal germination when the cooled tubers are placed under favorable conditions. The cold reduces the amount of sugar used in respiration and probably also causes an increase of diastase, the enzyme that converts starch into sugar. The same has been shown to be true also in the case of the dormant buds of many trees and shrubs. Exposure of dormant buds, bulbs, tubers, etc., to sulphuric ether for several days has a similar effect to that produced by exposure to cold. In the case of plants that have their dormant or resting period in dry weather there is an accumulation and modification of reserve foods preparatory to the next season of growth. Buds, bulbs and tubers may often be forced to grow before they have accumulated sufficient reserve food in the proper form, but the result is usually a weak plant very subject to disease. A good example of this may be seen in the attempt that is often made to force bulbs that are immature and that have not had their normal period of rest or have been forced the previous season. Variegation or mosaic disease is also often produced in this way.

Light.— Practically all the chlorophyllaceous plants are dependent upon sunlight for normal development and activity. Every individual and every species is adapted or attuned to a particular range of light intensity and suffers injury if the intensity becomes too great or too small, or if the change from one intensity to another is too sudden.

Injury from Strong Light.— Many bacteria and fungi, for example, *Bacillus anthracis* and *Botrytis cinerea,* grow best in darkness or very weak light, but are killed in a short time by exposure to sunlight or to artificial light strong in the blue-violet rays. It is this portion of the spectrum that causes the chemical disorganization of the protoplasm or rather its destruction by oxidation as in the absence of oxygen during exposure no change takes place. The same is true of the more highly developed chlorophyllaceous algæ and shade plants — too strong light not only destroys the chlorophyll by oxidation induced by the blue-violet rays, but the protoplasm itself may finally be thus killed or chemically disorganized. This is also well shown in the injurious effect of the ultra-violet rays in the naked electric arc light. A glass globe which cuts off these rays prevents the injury. This pathological condition in varying degrees of intensity is produced not only in shade plants when exposed to direct sunlight, but also in other plants when grown in the shade and suddenly exposed to strong light. It is also common when an extended period of cloudy or foggy weather in the spring is suddenly followed by bright, clear days. Under such conditions there is not only a partial destruction of the chlorophyll, but an excessive loss of water from the poorly cuticularized leaves. Such leaves are also unable to close their stomata quickly, which is another reason for their suffering from excessive loss of water. The action of light in promoting evaporation or transpiration is mainly by raising the temperature of the tissues above that of the surrounding air. When the air temperature is very high the increased temperature of the tissues of plants exposed to strong sunlight is often sufficient in itself to cause injury or death.

Injury from Weak Light.— While too strong light cannot be endured by any plant, lack of light is injurious only to cholorophyllaceous plants. When the light intensity is reduced below the minimum for any of these plants the synthesis of carbon and nitrogen compounds is reduced accordingly until in very weak light or darkness the plant can make no use whatever of the carbondioxide of the air. That the plant will starve in proportion to the reduction in photosynthetic activity is evident.

Electricity.— That electrical conditions of the earth and atmosphere and of the plant have an important relation to the physiological condition of the latter has been demonstrated in many cases, but the full significance of this relation is not yet understood. Plants vary in sensitiveness to electric currents in much the same way that they do to light or heat. A current above the maximum for a plant causes the disorganization and death of the protoplasm. This is often accomplished by a comparatively weak direct or alternating current, but is perhaps most familiar in cases of injury or death from currents of high intensity, as from electric-light wires or lightning stroke.

Mechanical Injury.— Finally, among the causes of disease in the non-living environment, we have to mention mechanical injuries, such as those produced by hail, wind, falling trees, etc. Hail stones often severely cut and tear the foliage of trees and herbaceous plants and may also produce more or less serious wounds in the more resistant tissues. Wind may injure the foliage, break limbs, etc., as may also falling trees. In all these cases, except in the most severe forms, the greatest danger comes from the entrance into the tissues of the wounded plant of parasitic insects and fungi. Large mechanical wounds, however produced, should have antiseptic treatment where practicable, especially in large and valuable trees. The injured parts should be trimmed to healthy tissue in such a manner as to favor rapid formation of callus. After a wash of some disinfectant, such as copper sulphate 1 per cent solution in water, the wound should be protected by shellac or grafting wax or white lead paint.

Diseases Caused by the Living Environment.

Struggle for Room.— The results of crowding are so familiar and apparent that discussion of the subject is scarcely required. The strong plants occupy the soil with their roots and the air space with their leaves and branches, crowding out the more backward or weaker individual or species. Some are thus starved to death, others are reduced in size and vigor according as they lack the proper space in which to grow.

Plant Associations.— Plant associations spring up controlled by certain dominant species. Each individual of such a community has its influence on the others. The shade of a tree keeps back some sun-loving species and makes it possible for shade-loving species to grow, and so, with countless inter-relationships, plant communities develop, often of great complexity. If the tree or other dominant factor is removed the changed conditions are followed by a breaking-up and readjustment according to the new conditions. Many of the former occupants

of the area will be starved or crowded out in the struggle. Others may suffer from excess of light or too high temperature. Disregard of the natural requirements of plants and their inter-relations in communities often leads to disastrous results in clearing or planting in landscape gardening.

Symbiosis.— This term was first used by De Bary to designate plant partnerships such as those represented by the co-operation of fungi and algæ in the formation of organisms known as lichens. The fungous hyphæ surround the algæ cells and furnish them with water and dissolved salts from the substratum, and the algæ in return supply to the fungus hyphæ the required organic nutrient materials. The community forms in itself a specific vegetable organism, though under favorable conditions of nutrition both the fungus and the algæ forming the lichen may live independently of each other. Another type of symbiotic relationship is found in the so-called *Mycorhiza* or fungus roots. These are specially common on plants growing in humus. Two types are distinguished, one where the fungus is in close external union with the roots, covering them with its filaments and preventing the formation of root hairs, actually taking their place by supplying the plant not only with water and mineral food but also with organic nutriment from the humus. These external associations are usually termed ectotrophic mycorhiza.

Monotropa hypopitys is a good example of a non-chlorophyllaceous plant dependent upon ectotrophic mycorhiza for its food. Among forest trees the phenomenon is very common especially in the *Cupuliferæ* and *Abietineæ*. That the fungus mantle in these cases supplies the host with food materials from the humus has been amply demonstrated. Ordinarily the host plant in these cases furnishes little or nothing to the fungus, which is able to obtain all its nutriment from the humus. In some cases, however, the mycorhiza fungus has been observed to penetrate the root sheath and become parasitic. It is a short step from this condition to the cases where the fungus is normally internal, forming the so-called endotrophic mycorhiza, as in many of the *Orchideæ, Ericaceæ, Epacrideæ, Empetraceæ* and representatives of other groups living in humus soils. In many of these cases, while the plants are not in any way apparently injured by the fungus, they can thrive as well without as with it, and the relation of the fungus to the host has not as yet been fully investigated. Among the *Leguminosæ*, however, the case is different. All legumes in their native soils have their roots covered with "tubercles." These develop as the result of stimulation produced by certain bacteria which enter the young roots through the root hairs and grow symbiotically within the cells. The bacteria draw their organic nourishment from the stores in the root and in return secure nitrogen directly from the atmosphere which afterward becomes available to the legume. Legumes with these tubercle bacteria can thrive in a soil absolutely devoid of nitrogen, whereas, without the bacteria, they could not live at all in such a soil. The failure of legumes to thrive in certain soils is often due to the absence of these tubercle organisms. On the other hand, the tubercle organism often degenerates into a mere parasite. Similar organisms are also found in symbiotic relation in the alder and in several other groups of plants.

Vegetable Parasites.— The true vegetable parasites (obligate parasites) are those which cannot, in any phase of existence or stage of development, live independent of the host plant. There are many true parasites both among the higher and lower orders of plant life. Many organisms, however, are parasitic during certain stages of their development and saprophytic in other stages; where the parasitic nature is predominant they are called hemi-parasites; if the saprophytic phase predominates they are classified as hemisaprophytes. All of these classes are responsible for the production of diseases of various types. The true saprophytes, which live entirely on dead organic matter, are seldom the cause of diseases. The disease of plants due to vegetable and animal parasites constitute by far the larger number of diseases and are those of greatest economic importance. In some cases, as previously suggested, it is difficult to determine whether we are dealing with a harmless symbiotic relationship or one where the host is more or less injured. In this doubtful category, for example, are to be placed the mistletoes (*Loranthaceæ*). These plants possess leaves containing chlorophyll and are related to their host the same as a scion to a stock. The true mistletoe of Europe (*Viscum album*) and its relatives in America (*Phoradendron flavescens*) are parasitic on a great variety of deciduous trees and sometimes do considerable damage. Here also must be placed those endotrophic mycorhiza of many plants growing in humus where neither benefit nor injury has been shown as a result of the presence of the fungus in the roots. Among the phanerogams, however, there are many true parasites, for example, the *Orobanchaceæ*, which are devoid of chlorophyll and derive all their nourishment from the roots of the host plants to which they are attached. These parasites often do considerable damage to tobacco, hemp, lucerne, clover and other crops. The Dodders (*Cuscuta*) are also true phanerogamic parasites, deriving all their nourishment from their host plants, which they overrun and penetrate with their sucker roots (haustoria). The most dangerous and prolific disease-producers, however, are the pathogenic fungi and bacteria.

Pathogenic Fungi.— The consideration of diseases caused by pathogenic fungi is usually based upon the fungus and the genetic relationships of the fungi usually determine the order in which the diseases are discussed.

While this practice is undoubtedly the best one to follow in a systematic treatise, it is probably the cause of the erroneous impression sometimes encountered that the fungus is the disease. The disease is the functional or cell derangement of the plant or part of the plant. The same functional or cell derangement and, therefore, strictly the same disease, may in some cases be produced by a great variety of totally unrelated causes. More attention should be given in plant pathology to the study of the disease itself; though not less attention should be paid to the determination and study of the cause. This latter course is especially necessary in the case of the pathogenic fungi, bacteria or insects. A complete and accurate knowledge of the life history and nutritive re-

quirements of pathogenic organisms furnishes the best foundation on which to base the procedure for preventing or controlling the diseases caused by them. As already suggested, there is every possible gradation among the pathogenic fungi, between the strict saprophyte (such as sooty molds), causing disease only by chance association, and the strict parasite (such as rusts and smuts), unable to exist independently of their living hosts.

Among the diseases caused by strict saprophytes may be mentioned the starved and chlorotic condition of many leaves and fruits due to the presence of sooty molds on their surface. These black, mold-like fungi grow in sugary excretions, especially the "honey dew" excreted by insects, aphides, scales, leafhoppers, etc. This black growth, where it covers the surface of leaves, occasionally cuts off so much light that the chloroplasts lose their green color, and the formation of starch and sugar is so greatly reduced as to cause partial starvation and general retardation of growth of the whole plant. This is intensified by the injury produced and the food removed by the insects.

Many of the saprophytic yeast fungi, molds and bacteria cause fermentive decomposition in the weakened and dead cells of the wounded tissues, especially those rich in sugar or other reserve materials. Toxic products are thus produced which weaken or kill all the cells absorbing them. Such fermentations are especially common following mechanical injury to ripening fruits and to the sapwood of trees, in the latter case particularly following the work of borers. Fungi of this class grade imperceptibly into the hemisaprophytes or facultative parasites which start their vegetative development in dead or weakened tissues like the heartwood of a tree or the dead tissue of a wound, and then gradually spread into the living tissues, killing them. The best examples of this class are the wood-destroying *Polyporeæ* (bracket fungi), *Agaricineæ* (toad stools), and related fungi. When these get into the heart-wood through a wound, or into an area of dead cambium bark or sapwood, they first kill the dead area with their mycelium and gradually spread into surrounding living tissue, in some cases by secondary action through decomposition products, or by cutting off the water or food supply from the living tissues, or by primary action, where the mycelium spreads from its saprophytic vantage ground directly into the neighboring living tissue.

In order to prevent wound infection of woody plants it is necessary either to keep the surface of the wound dry, preventing the exudation of sap and the entrance of water by searing with a hot iron, or by treating the injured surface with an antiseptic or protective coating, paint or wash, such as coal tar, white lead, copper sulphate, etc.

Besides the hemisaprophytic wood-destroying fungi which gain entrance through wounds and are not able otherwise to infect a sound plant there are others of the same class, such as *Agaricus melleus,* whose mycelial strands or rhizomorphs are able to work their way through the sound bark of numerous conifers, underneath the bark and in the wood of which the fungus produces dense white, felt-like mycelial membranes. These kill the bark and wood and stimulate an excessive flow of resin into the injured parts, finally resulting in the death of the tree. This same fungus also attacks deciduous broad-leaved trees, but here it is more particularly a wound parasite.

Botrytis, Pythium, Sclerotinia and many other fungi, though able to pass the whole of their existence as saprophytes, are also able under favorable conditions to infect the living tissues of plants and destroy them. It is a short step from these fungi to those of a slightly more decided parasitic nature, the *hemiparasites,* organisms which cannot in nature complete their life history as saprophytes. The *Ustilagineæ* (smuts) are among the most familiar examples of this class. These grade imperceptibly into the strict parasites such as the *Uredineæ* (rusts), which cannot live at all as saprophytes.

Among the strict parasites there is often a high degree of specialization, a given species of fungus being restricted in many cases to a particular genus or even species of plant. In some of the rusts there is a peculiar phenomenon of this nature known as heteroecism. Many species of rusts go through their whole life history producing all their various forms of spores on the same host. In other cases, however, spermatia and æcidiospores are produced on one host and the uredospores and teleutospores of the same fungus are produced on an entirely unrelated host.

Injury Caused by Parasitic Fungi.— It is extremely difficult to classify the various reactions of plants to parasitic attack. Every case has to be considered in a large measure individually. There are, however, certain general types of reaction and injury that may be noted. There are many parasitic fungi, for example, that attack the leaves of plants; some of these, like the powdery mildews, grow only on the surface of the leaves and younger stems, forming powdery, whitish spots or coatings and drawing nourishment from the surface cells by sending down into them short, root-like growths, *haustoria.* When these surface parasites attack the young growing leaves, stems or fruits, the areas occupied by the fungus are greatly retarded in development, often causing more or less distortion of the leaves, and in severe cases often killing them and causing early defoliation. The flowers and fruit may thus also be destroyed. The proper ripening and maturation of the wood of perennials is often so much retarded by these direct and indirect effects that it winter-kills. When these fungi, however, attack only a few leaves on a plant, or where they attack the leaves after they are full grown, the injury is comparatively slight. Prompt burning of the fallen leaves in autumn is one of the best preventive measures. Sulphuring, so widely practised in the case of vine mildew, helps to rid plants of the fungus, and spraying with Bordeaux mixture is a good preventive as well as curative treatment.

Besides these external parasites there are a large number which penetrate and vegetate directly in the cells or in the intercellular spaces of the host. Some of these after a time kill the tissues in which they are growing, producing a dead area. If these dead areas are in the leaves and are numerous or large, the value and working power of the leaf may be seriously impaired or destroyed altogether. The destruction of the first crop of leaves often results

from the attack of leaf-spot fungi early in the summer, and the plants are obliged to put out a second crop of foliage. This must be done at the expense of reserve food stores. In such crops as sugar beet, Irish potato, etc., this use of reserve food becomes evident in the reduction of yield of tubers and sugar. In crops like beets and potatoes, where there is a continual succession of new growth, a second attack is not so serious as in the case of trees and shrubs where two successive defoliations either kill the plant outright or so weaken it that it winter-kills or dies of starvation. The weakening effects of premature defoliation are often not fully realized. Where one premature defoliation has occurred from any cause, great effort should be made to protect the second crop of leaves and to stimulate the plant with nitrogenous fertilizers. If the plant is a perennial, some protection, if possible, should be furnished during winter, as the wood is likely to be poorly ripened. Practically all the leaf-spot diseases are easily controlled by spraying the foliage with Bordeaux mixture or other good fungicide. Immediate removal, if possible, and burning of the diseased leaves also serve to hold these diseases in check.

If prompt action of this kind is taken when the trouble first appears it may often be checked without other treatment. It is safest, however, to spray the plants with a fungicide, whenever practicable.

Many fungi which may start by attacking the leaves are not limited to them, but spread to or even directly attack the stems. The *Peronosporeæ*, or downy mildews, are good examples of this class. Plants which have developed in moist, cloudy weather are particularly sensitive, and the parasite starting in leaves or stems may in a few days invade all the tissues of the plant, causing a rapid soft rot. The well-known "potato rot," often causing the complete destruction of the crop in a few days, is caused by one of this group of fungi. Many other crops are similarly affected by fungi of this group. Like the leaf-spot fungi, these are easily prevented from gaining entrance to the tissues of plants by keeping them well sprayed with Bordeaux mixture or other good fungicide.

The root rot and damp-off fungi — *Rhizoctonia, Ozonium, Agaricus melleus, Botrytis, Pythium, Fusarium*, etc., usually attack the plant through the roots or base of the stem, and cause a more or less rapid decay of the invaded tissues, followed by the starvation and death of the whole plant.

The cultivation of resistant individuals or the use of uninfected or sterilized soil and attention to general cultural conditions, especially rotation of crops, drainage and aeration of soil, are the best preventive measures for diseases of this type.

In other cases stems and leaves may be invaded by fungi (rusts or smuts), but rotting or sudden death of the tissues does not occur. The plants may, however, be so reduced in vigor that they fail to mature. The cereal rusts, for example, often greatly reduce the yield of grain. In case of the smuts the grain is replaced by the spores of the fungus, but the plant is apparently not otherwise injured.

Hypertrophy.— In some cases the tissues attacked by fungi are stimulated to excessive growth. Finger and toe disease of turnip roots caused by *Plasmodiophora*, plum pocket and "leaf curl," "witches' brooms," etc., caused by *Exoascus*, the large galls on *Vaccinium* and *Rhododendron* caused by *Exobasidium*, the large swellings produced on conifers by *Peridermium*, etc., are good examples.

Pathogenic Bacteria.— The casual relation of bacteria to numerous animal diseases has been the subject of much careful study, but until recently there were only a very few plant diseases known to be caused by these organisms.

Among the best known examples may be mentioned the "fire blight" of pomaceous trees, especially pear and apple. The tops of the trees are killed back as if burned by fire. The bacillus causing the trouble is carried from tree to tree by bees and other insects. The principal infection is through the nectaries of the flowers, and possibly, also, through the glands or water pores of the young leaves. The twigs are usually killed back for a few feet, then as the wood begins to mature the bacteria usually die, except where they have invaded a large limb or the body of the tree. To prevent the disease being carried over from season to season it is necessary only to find and remove all these latter sources of infection.

A bacterial disease of the English walnut on the Pacific Coast is a serious menace to the culture of these trees. A bacterial gall or tumor of olive trees is serious in Europe, and has appeared in some of the olive groves of California. Among the bacterial diseases of vegetables may be mentioned the bacterial rot of the tomato, egg plant and Irish potato, carried by biting insects, the brown rot of cabbages, and a bacterial disease of sweet corn entering the tissues through water pores in the edges of the leaves. Numerous other plant diseases have been shown to be due to bacteria, and the number will probably be greatly increased as the field is more carefully worked.

Diseases Caused by Animals.— Next to diseases of vegetable origin, those caused by animals, especially insects, are the most numerous and destructive. Many fungus and bacterial diseases are carried from plant to plant by insects; for example, pear blight by bees, potato rot by potato beetles, ferment and wood-rot fungi by boring beetles, etc. In the case of pear blight the bees, though they are carriers of the disease, are beneficial to the trees in aiding pollination. In other cases the injury caused by the insects may in itself be serious. The biting insects may in some cases cause more or less complete defoliation, or the sucking insects and mites may so reduce the stores of plant food as to seriously interfere with growth. Among the best known and most injurious of these are the scale insects, mealy bugs, plant lice (*Aphidæ*), leaf hoppers, and the "plant bugs" (*Capsidæ*). All of these feed on the sap of the plant by sucking it out of the tissues, but causing little or no mechanical injury to the cells. In many cases there is simply a general or local retardation of growth due to the removal of sugars and proteids; in other cases irritations are set up, possibly by some material injected into the tissues by the insect, resulting in gall-like swellings or various hypertrophied developments of the parts attacked, for example, *Phylloxera* on the leaves and roots

of grape; woolly apple louse (*Schizoneura*) on roots of apple; *Colopha*, cockscomb gall on elm, etc. In other cases the growth of the tissue is checked, as where tissues are attacked by scale insects such as San José scale, and by many of the plant lice and leaf hoppers. In other cases growth is neither checked nor accelerated, but definite spots are produced which continue to enlarge, resembling a fungus or bacterial infection (*Stigmonose*) or puncture diseases, etc.

Borers may more or less completely ring a tree, cutting off the connection between root and leaves and thus resulting, in many cases, in death. Hypertrophy of tissues is also often the result of insect attack. Many insect larvæ developing from eggs laid in young tissues cause, by the irritations they set up, growths known as galls. Nematode worms attacking the roots of plants also cause gall-like swellings.

As in the case of the fungi, the complete life history and habits of any particular injurious insect must, as a rule, be determined before the greatest success in controlling it can be attained. Many insects have their natural enemies, which, if favored, may hold a serious pest in check. The development of natural resistance in plants by selection is also an important means of preventing injury in certain cases. And finally, the use of insecticides must be resorted to, as arsenic, etc., for biting and eating insects, and contact poisons for sucking insects.

PLANTS, Embryology of. See EMBRYOLOGY OF PLANTS.

PLANTS, Fertilization in. See FERTILIZATION IN PLANTS.

PLANTS, Food of. Two classes of definitions have been applied to this term. Those formulated by agriculturists include all such substances as plants can assimilate from soil or air, anything adapted to form tissues and sustain the growth, functions and reproduction of plants, such as natural materials, manures or fertilizers. Botanists, on the other hand, exclude all these materials and limit their definitions to those substances elaborated or manufactured by and within the plant organism itself for building cellular or other tissue or cell contents. What the former considers as plant foods the latter calls plant food materials. Of the two definitions the first given is the most widely accepted because the most rational and satisfactory. From the agricultural standpoint the definition is generally extended to include those substances which supply perhaps only one element of their composition but which is essential to some function of the plants. Some of the elements secured are built into the cell tissue; others are contained in the protoplasm or other materials with which the cells are filled. When plant foods are readily taken up by plants they are termed *available foods*; when not easily assimilated *unavailable foods*. The latter must pass through changes of various kinds before they can become available. Without exception, however, both available and unavailable foods when secured by the plant from the soil must be in a form soluble in water.

In order to attain normal development every plant requires 10 or more substances which are called essential elements because the lack of any one will interfere with growth and development and in time prove fatal. These elements are carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, potassium, calcium, iron and magnesium. The first four of these and sometimes the fifth and sixth are called "organogens" because they are considered as charasteristic of organic compounds. Besides the 10 elements mentioned most plants also contain silicon, sodium and chlorine, but these have not been proved essential; usually plants seem to grow more normally with than without them.

The physiological functions of these various foods have been largely determined by experiments but in some cases much remains to be discovered. A knowledge of these functions is of profound importance in crop production, especially since manuring, fertilizing, tillage and many other farm practices may be more intelligently carried on when they are understood. Briefly the principal rôles are as follows:

Carbon enters through the leaves where by means of photosynthesis (q.v.) it combines with water to form the foundation compounds of which starches, sugars, cell tissue and other carbon-containing organic substances are the final or resultant products. Thus carbon becomes the most important organic element, not only within the plant, but in nature, because all its naturally occurring organic compounds, whether in plants, or as assimilated by animals, or deposited as coal, oil or gas, trace back to it via nature's chemical laboratories in the leaves and other green parts of plants.

Oxygen ranks next to carbon as a constituent of the dry matter since it is in almost all plant compounds. It is also essential to respiration (q.v.), to oxidation of materials and thus to the development of energy in the growing plant. When combined with hydrogen in the form of water it is both the main solvent and the transporting vehicle for crude and elaborated plant foods dissolved in the "sap." Water also performs several other functions in plants; for instance, maintaining turgor, reducing temperature through evaporation, etc.

Hydrogen enters into every organic compound excepting neutral oxalates in plants, yet because of its extreme lightness plants contain only about 6.5 per cent of it.

Phosphorus is largely used by plants to make proteins, cell nuclei, to stimulate growth of seedlings, increase root growth, divide cells, ripen the seed and to reduce the content of nitrogen in cereal seeds. When plenty of it is in the soil, especially during a dry season, plant roots are able to penetrate deeper than they could otherwise and thus tap surer sources of water. When applied as fertilizer in the drills of corn and other crops it stimulates the crop, as in the practise of the New England Indians who deposited a dead fish in each hill of corn.

Potassium is necessary to the manufacture of the carbo-hydrates in plants, for the hydrolysis of starch, the production of cell tissue to help give rigidity to stems, to help resist fungous diseases, strengthen leaf development, increase yields of potatoes, sugar beets and other crops rich in starches or sugars, to neutralize

acids, produced by plant growth and to heighten the color of fruits.

Nitrogen is essential to the production of proteins, the formation of protoplasm, chlorophyll (qq.v.) and many other compounds. It stimulates plant tissue, especially of leaves which it makes large and dark green, as every market gardener can testify from his experience in using it upon cabbage, spinach, lettuce and other pot herb crops. Over-stimulation with it delays seed maturity, tends to make plants weaker stemmed and tender to frost and to disease, thus acting opposite to phosphorus and potassium.

Sulphur helps to make most proteins and many flavoring oils such as in onion, cabbage and mustard.

Calcium, like potassium, helps dissolve and transport starch, develops strong cell walls and root hairs, precipitates oxalic acid which is formed by plant activity and unless crystallized would poison the plant.

Magnesium aids the formation of chlorophyll, of proteins, the assimilation of phosphorus and the development of seeds presumably as a carrier of phosphorus in the plant.

Phosphorus and nitrogen migrate to the seeds during the ripening process so that there are often two or more times as much of these in the seeds at that time as in other parts of the plant. Potassium and calcium remain in the stems then to aid in assimilation — two or three times as much of the former and almost eight of the latter as in the seeds. Sulphur and magnesium are more uniformly distributed. Iron is largely in the green coloring matter.

About 75 per cent of the live weight of plants consists of water. The balance is termed "dry matter" which is either taken up or manufactured by the plant. It consists mainly of organic material in about the following proportions: Carbon, 11 per cent; oxygen, 10 per cent; hydrogen, 2 per cent. The balance includes the nitrogen, part in organic form and part in the "ash," or residue left after burning. All of these ash elements are necessary in the formation though not part of the fundamental plant substance.

Foods reach the interior of plants in two ways, through the air and through the soil; practically all the carbon and much of the oxygen in the former and part of each combined with certain ash elements in the latter by which way also the other elements enter in the form of various compounds such as phosphates, nitrates, sulphates, carbonates, etc., always in solution. When taken up by the roots soil water becomes sap which passes from cell to cell till it reaches various kinds of conduits which direct it to the leaves and other parts of the plants, where needed.

The absorbing parts of the roots have a selective action which allows helpful substances to enter but to a greater or less degree prevents the entrance of phosphites, nitrites and sulphites, etc., which are not plant foods but plant poisons and so would prove harmful. This selective action is still more refined, for at times when the plant may be in special need of nitrates it will seize these but take up little or no phosphates, though the case may be reversed or both be equally absorbed at another time. Again the protoplasmic layer of the roots may appropriate the nitrate from nitrate of soda or some other salt by chemico-physiological processes but leave the undesired sodium in the soil. PLANTS, Lore of. Quite apart from all the fancies connected with flower language and symbolism (see FLOWERS, SYMBOLISM OF), there is an abundant stock of traditionary lore associated with all kinds of trees, plants and flowers. The study of this throws much light on many puzzling survivals in folk-lore, and some writers have shown its importance for part of the problem of primitive religion. Among Australians and red Indians the totem often takes the form of a plant or tree, for which the individual shows his reverence by refusing to gather or destroy them. The worship of trees is widely prevalent among savages everywhere, and there is ample evidence that it was an important element in the religion of all the families of the Aryan stock. Grimm thinks the oldest sanctuaries of the Germans were natural woods, and hints at a historical connection between the ancient sacred inviolate wood and the later royal forest.

The oak-worship of the ancient Druids, the sacred fig-tree of Romulus in the centre of Rome, the *Ficus religiosa* of India, and the sacred groves of the Semitic and pre-Semitic races still surviving at Carthage a century after Augustine, are ready examples of tree-worship from sufficiently wide centres of civilization. The primitive mind of the savage readily conceives of a tree as animated by a conscious soul cognate with his own, and he may regard the tree either as its permanent outward organism or merely as its characteristic dwelling-place. Hence trees have their place in fetishism, idolatry, and the upward development of religion. Buddhists do not include trees among sentient beings possessing mind, but recognize the existence of the genius of the tree, and Buddha himself was regarded as such no less than 43 times during his transmigrations. The reverence paid to the famous bo-tree shows how fundamental a fact is tree-worship, which undoubtedly formed a large part of the old Hindu religion amalgamated by the new philosophical faith.

But the sacred tree and grove are likewise to be found within the range of Semitic and Aryan influences. From all sides appears evidence at once of the great antiquity and uniformity of the worship of trees, whether for the services they render to man, for their venerable antiquity, their form, for particular qualities ascribed to them as containing the seeds of fire, for their situation, as on sombre and lonely mountain tops, or for their association with certain phenomena, as plagues and pestilences, or certain events in the history of the homestead. In the growth, life, decay and death of the plant the primitive man easily sees an

analogue to his own life-history, and herein we may find the philosophy of the widespread rustic rites associated with marriage and with the birth of children. The custom of scattering flowers and the fruits of the field over the footsteps of a newly married pair conveys an obvious reference to the belief in the reproductive powers of vegetation. Primitive ideas of the fertilizing and fruit-bearing powers of nature led to the belief that each tree or plant possesses spiritual as well as physical life, being tenanted either by semi-divine spirits or by the ghosts of the dead, and a natural generalization of this notion made plants and trees collectively the abode of particular inhabitants — an example of animism developing into polytheism.

A forest-god has been deduced from a mere tree-soul, both alike regarded as powerful to produce rain or sunshine, to cause fruits to spring and cattle easily to bring forth their young. A still higher generalization gave a belief in a genius of plant-life or forest-life, or, higher still, a genius of growth or fertility in general. This universal genius of growth was symbolized by a bush or tree, brought in triumph from the forest, gaily decked, and solemnly planted near the homestead or in the village. In many cases the tree-spirit was regarded as detached from the tree and clothed in human form as a man or girl decked with flowers — the May-king, Queen of the May, the Old Woman or Corn-mother of German harvest-fields, the Jack-in-the-Green of young London sweeps, and the like. The existence of those corn spirits which especially haunted and protected the waving corn is dimly recognized in characteristic ceremonies of an English harvest-home, and in the French and German observance of the Harvest May, in which a branch or tree decked with ears of corn is carried home in the last wagon from the harvest-field and hung on the roof of the farmhouse till the next year.

Sympathetic affinities between plant and animal life strongly impress the primitive imagination and play an important part in many cosmogonies, as in the Iranian account of how the first human pair grew up as a single tree, the fingers or twigs of each one folded over the other's ears, till the time came when they were separated, and endowed with distinct human souls. Other mythical cosmogonic trees are the heavenly fig-tree of the Vedas, and the ash-tree Yggdrasil of Norse mythology. The belief that a child's rickets can be cured by passing him through a cleft ash-tree till lately lingered in corners of England, and stories of trees giving forth human groans and exuding human blood are common in folk-tales everywhere. Families, as well as individuals, have tutelary or guardian trees.

Even the Christmas-tree, which originally made its way into England and France principally through the influence of Prince Albert and the Duchess Helen of Orleans, is really a survival of an ancient German custom of heathen origin. Many plants have received a kind of religious consecration from the name of some saint whose festival fell on the day on which they were gathered. Christianity, like Buddhism, early showed a marvelous adaptability in the way in which it adopted popular rites of an earlier religion and rebaptized them as its own. Many remnants of primitive superstitions survive in the local English names of plants and flowers, chiefly in connection with the fairies, the devil, the Virgin and the Cross, and we have a great wealth of association from one cause or other between saints and flowers, as Saint Agnes with the Christmas rose, Saint Joseph of Arimathea with the Glastonbury thorn, Saint Patrick with the shamrock, the Virgin with the white lily, just as Thor had its oak-tree, Venus her myrtle, the Indians the lotus, and the Druids the mistletoe. Again, historical personages and families are frequently associated with particular flowers — it is enough merely to name the orange lily, the red and white roses, the fleur-de-lis, the planta genista, and the violet. Family and clan crests frequently take this form, as the fir, holly, juniper; also national badges, as the rose, thistle, shamrock.

More curious and interesting, though obscure, are the notions of magical properties connected as persistently with some plants as medicinal properties are with others. Most prominent in European folk-lore are the elder, the thorn, and the rowan or mountain ash; but strange properties are still ascribed to the rosemary, vervain, Saint-John's-wort, mandrake, asphodel, and to fern-seed; and many flowers lend themselves through some obscure inherent fitness to special methods of divination. The doctrine of signatures, so important in the history of medicine, opens up a special chapter of sympathetic magic, involving the belief that plants bore by nature marks indicating plainly for what diseases they were medicinally useful. The trees of Paradise, of Chaldæan and other cosmogonies, the oracular oaks of Dodona, those trees of healing spiritually allegorized in the Apocalypse, the trees of Liberty and the French Revolution, and the trees round which an Indian bride and bridegroom walk hand in hand point as unmistakably to a real sympathetic affinity between the human and the vegetable world as did the Dryads, Fauns and Satyrs of the ancient Hellenic mythology, with their analogues the elves and fairies of the woods, the transformation-myths, the Orpheus whose lyre laid its charm on beasts and trees alike, or the Pan at the report of whose death all nature mourned aloud. Consult Dyer, 'Folk-lore of Plants'; Frazer, 'Golden Bough.'

PLANTS, Malformations in. Malformations in plants are more or less conspicuous growths or deformities which do not occur in the normal life history of the plant but are caused by various agencies, such as insects and other animals, fungi and other plants, and sometimes by merely mechanical accidents, and sometimes by agencies which are entirely unknown.

Most of the conspicuous malformations caused by insects and by other plants are called galls (Fig. 1). The gall-flies (Cynipidæ), the gall-nats (Cecidornyiidæ), mites, caterpillars and the larvæ of the beetles are the most frequent causes of galls; but many are caused by fungi. In most cases the depositing of an egg by an insect is the stimulus which initiates the formation of abnormal tissues and outgrowths; but in many cases, the principal stimulus comes later, in the development of the larva from the egg. The nature of the stimulus still needs

investigation, but it has some of the characteristics of fertilization; at least, there is a stimulus to growth and development. Whether there is any transmission of hereditary characters or not is a question; but it is an undeniable fact that certain insects produce certain galls with such distinct characters that analytical keys can be constructed for the identification of galls.

FIG. 1.— Gall on leaf of White Oak: a sectional view is shown below, at the right. The harder, inner part, suspended by strands, contains the grub.

Galls occur in every great group of plants, even in the algæ and fungi; they are not numerous in the Bryophytes, the liverworts being particularly free; in the Pteridophytes they are more numerous. In the Gymnosperms, there are many galls, some of them, like the "Witches Broom" and "Cedar Apples," being very conspicuous. In the Angiosperms, especially in the Dicotyls, galls reach their maximum in display, distribution and variety. No less than 901 different kinds of galls are found in the Fagaceæ, the family which includes the beech, chestnut and oak, the latter having more kinds of galls than any other plant. The Compositæ (Sunflower Family) come next with 664, followed by the Salicaceæ (Willows and Poplars) with 573, the Rosaceæ (Rose family) with 500, the Leguminosæ (Peas, Beans, etc.) with 481, the Cruciferæ (Mustard, Radish, Turnips, etc.) with 256, the Labiatæ (Mint family) with 217 and various others ranging down to a single gall. Among the Monocotyls, the Gramineæ (Grasses) lead with 193, no other family having even as many as 50. Many families, both in Dicotyls and Monocotyls, are entirely free from galls.

A gall may consist of a single cell or of many cells which have been modified by the infection, producing distortions without adding to the number of cells; or the infection may stimulate cell division and growth, building up extensive new tissues with characteristic forms. In plants which are normally hairy, the hairs may be enlarged and modified in shape, but the infection often results in the formation of hairs on plants which are normally smooth, as in case of the common basswood. The leaves are quite smooth, but when infected, the epidermal cells grow out into long hairs (Fig. 2). In this connection it is of great interest to note that not only may structures, like the hairs, be produced in plants which are normally smooth, but it is claimed the structures called forth by the stimulus may resemble those of closely related species.

Entire leaves are often greatly reduced and distorted, their margins may be folded in and adjoining surfaces may grow together. Flower clusters are often modified and young vegetative shoots may be greatly reduced, so that the leaves become crowded and make the shoot look like a cone, as ofter seen in the willows. In some Composites, like the sunflower, the infection causes a distorted vegetative development to take the place of floral development and the head looks like a modified involucre.

Large swellings are often caused in the stems of herbaceous plants, the galls on stems of golden rod being familiar examples. The more or less spherical galls on rosebushes and on leaves and twigs of oaks are often highly colored. The large spherical gall, often an inch in diameter, found on oak leaves and twigs, is a good example of a very complicated gall (Fig. 1). At maturity, it is dry, papery and hollow, with slender strands suspending a hard portion within which is the insect.

Many malformations caused by plants come within the category of galls. Some of these take the form of conspicuous irregular distortions; while others are scarcely noticeable blisters or spots on leaves or stems, or may be merely internal malformations, not visible from the outside. Perhaps the most familiar gall of the irregular distortion type is the corn smut, caused by the fungus, *Ustilago Maydis*. On the young ear of corn this gall becomes as large as one's fist, and on the tassel the distorted portions may be as large as hickory nuts or walnuts. Similar galls, not so large, but caused by related fungi, are very numerous. The smut on wheat and oats and other cereals are only too well known examples. (Figs. 3 and 4).

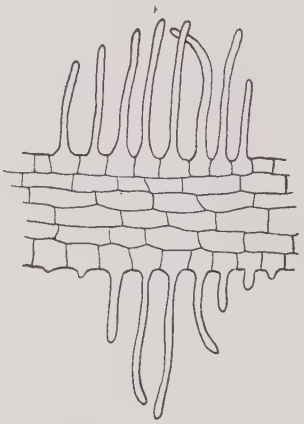

FIG. 2.— Filamentous gall on leaf of Basswood.

The "Club Root" of cabbage, cauliflower, turnip and other members of the Crucifer family is a large gall caused by *Plasmodiophora brassicæ*, one of the Myxomycetes (Fig. 5). The knotty swellings prevent the normal functioning of the root and thus stop the growth of the head and finally kill the plant. The spores of the fungus will live in the soil for years.

The «Black Knot» caused by the fungus, *Plowrightia morbosa,* is very destructive to cherry and plum trees. The infected twigs become swollen, often to several times their normal diameter, and the disease becomes so deep seated that the branches are killed. In

Fig. 3. — Rust of wheat and oats; the æcidium, or cluster cup stage on leaf of Barberry. The rust appears as yellowish spots.

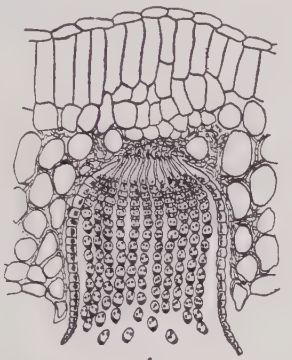

Fig. 4. — A greatly magnified view of a section of one of the cluster cups on Barberry leaf.

1906, «Black Knot» had become so destructive to cherry trees in North Carolina, that cherry-growing was practically abandoned in that State, and at one time this disease almost put an end to the cherry industry in Maine. Infected twigs should be pruned off in the autumn or early winter and destroyed.

The «Cedar Apples» of the Red Cedar, *Juniperus virginiana,* are interesting galls caused by the fungus, *Gymnosporangium.* The cedar twigs are infected in the autumn and the gelatinous, yellowish galls appear in the spring. They consist of great masses of teleutospores

Fig. 5.— The " Club Root " gall on roots of a turnip.

which promptly germinate putting out a short tube consisting of four cells, each of which produces a spore. These spores germinate on young quinces, june berries, hawthorns and apples, or on the young twigs of these trees, causing destructive malformations. Since the fungus cannot complete its peculiar life history without the cedar apple stage, the disease can be eradicated by destroying the junipers in the vicinity of the orchards.

The «White Rust» caused by the fungus, *Albugo candida,* is rather common on the «Shepherd's Purse,» *Capsella,* and upon various other members of the Mustard family. On the stems, leaves and flowers of *Capsella,* it forms blister-like white galls, which rupture the epidermis and scatter the asexual spores. It also develops a sexual stage, usually on the upper part of the stem or on the flowers, causing considerable distortion but not rupturing the tissues or causing any change in color. On the other hosts, the sexual stage may cause a distinct change in color.

One of the most familiar galls is seen in the «root tubercles» of the Leguminosæ (Pea family) caused by bacteria (*Rhizobium radicicola*). These swellings, or tubercles, enable the plant to make use of free nitrogen in the soil. Clover is abundantly supplied with these root tubercles which not only add to the vigor of the clover, but improve the soil.

A peculiar gall caused by «Bacterioids» associated with a blue green alga (*Anabaena*), is found on the rootlets of the cycads. The infection causes the rootlets to swell to several times their normal size and changes the direction of their growth, so that instead of growing down, they grow straight up and emerge above the surface in profusely branching coralloid masses.

One of the most remarkable and most thoroughly investigated of all galls is the «Crown Gall,» which has been called a plant cancer and is caused by *Bacterium tumifaciens.* It is very destructive to the apple, peach, plum, cherry, apricot, blackberry, grape, potato, tomato, tobacco, turnip and many other crops. It is particularly disastrous to young plants in the nursery. The bacteria have been isolated in many cases and from pure cultures obtained in this way many species have been inoculated and the characteristic galls have been induced, so that the relation between the bacteria and the galls has been established. The development of the disease closely parallels the progress of cancer in man and animals. In both cases, there is some stimulus to internal cell division. In case of the «Crown Gall,» that stimulus is a definite organism, but in man no definite organism has yet been discovered. The results of investigations upon the crown gall make it seem probable that some organism may yet be found to be the cause of human cancer.

Some malformations caused by large plants have been classed as galls. As the mistletoe grows into the branch of its host, the host is stimulated and grows up around the base of the parasite. When the parasite dies and falls off, the outgrowths of the host, with the characteristic markings left by the parasite, are called «Wooden Roses.»

There are many malformations in plants not caused by either insects, fungi or other plants One of the commonest of these malformations is known as *fasciation.* A familiar example is often found in the dandelion, where the flower scape, instead of presenting its usual tubular shape, becomes broad and ribbon-like. Many plants show deformities of this sort. Various malformations are found in flowers, the most

common being those in which one floral organ takes the form of another or in which a floral organ takes the form of a leaf. In the doubling of roses and many other flowers, the stamens become petals, or rather, the embryonic growths which normally would have developed into stamens, develop into petals. Similarly, we sometimes find leaves where we should expect to find carpels, which form the ovary. Any of the floral parts, sepals, petals, stamens and carpels may be replaced by leaves, and this fact is cited as proof that they were all leaves originally and that they have been modified to their present form from which they occasionally revert to the ancestral leafy condition.

The leaves of ferns, especially in greenhouses, often become greatly modified. Plants of the "Boston Fern" type often have leaflets which branch repeatedly at the tips, so that the plant bears little resemblance to the type. *Pteris cretica,* which normally has entire leaflets, has given rise to varieties with leaflets profusely branched.

The navel orange is a very valuable malformation due to an excessive enlargement of the axis just below the portion which constitutes the fruit in seedy oranges. The "Navel" of the navel orange represents the whole orange of the normal type.

Most of the literature on malformations is found in works dealing with galls and with various plant diseases.

No. 255, 1912); Masters, M. T., 'Vegetable Teratology' (London 1869); Heald, F. de F., 'Manual of Plant Diseases' (1926).

CHARLES J. CHAMBERLAIN.

PLANTS, Medicinal, plants of which some part is used in medicine or from which some preparation is extracted for similar purpose. To persons unacquainted with the nature of the various wild plants which surround them in farm and outdoor life, it comes as a great surprise to find that the world's supply of crude, botanical (vegetable) drugs are for the most part procured from the leaves, bark, seed, flowers, rhizome, etc., of these very plants, many of which are regarded as noxious weeds. The most valuable drug-plants which grow in America, from the point of view of the grower, are ginseng and golden seal (qq.v.), but there are all told more than 1,000 different plants which are indigenous or naturalized in the United States alone. Some of these are very valuable and have, since their medicinal properties were discovered, come into use in all parts of the world, others now collected in the United States have been brought here, and much, like the English sparrow, become in their propagation a nuisance and a pest to the farmer. The limitations of the present article preclude any extended discussion of the methods and habits of growth of the several plants, the methods of planting, cultivating, curing, preparation or extraction of the drugs, prices, etc. This information will be found, in the case of the more important plants, in the articles on these plants, v.g., Ginseng. It is intended here merely to set forth briefly those plants having a medicinal value, indicating the part or parts so used, and the general uses of each. As in the case of many native medicinal plants the early settlers in America learned of the virtues of Golden Seal (*Hydrastis canadensis*) through the Indians, who used the root as a medicine and the yellow juice as a stain for their faces and a dye for their clothing. Golden Seal is also known by different names in different localities, most of them bearing some reference to the characteristic yellow color of the root, such as yellow root, yellow puccoon, orange root, yellow paint, yellow Indian paint, golden root, Indian dye, curcuma, wild curcuma, wild turmeric, Indian turmeric, jaundice root and yellow eye, eyebalm, eye root and ground raspberry. The rhizome or rootstock and rootlets are the parts used in medicine. When dry the root measures from one to two inches in length and from one-eighth to one-third of an inch in diameter. The Indians regarded Golden Seal as a specific for sore and inflamed eyes and it was a very popular remedy with pioneers of Ohio and Kentucky for this affection, as also for sore mouth, the root being chewed for the relief of the last-named trouble. The juice is also used as a diuretic stimulant and escharotic, the powder for blistering and the infusion for the dropsy. It is useful in digestive disorders and in certain catarrhal affections of the mucous membranes. In 1860 the root was officially listed in the United States Pharmacopœia. The plant is native from southern New York to Minnesota and south to Georgia and Missouri. It is estimated that the average consumption of Golden Seal root is from 200,000 to 300,000 pounds annually, about one-tenth of which is exported. Consult Bulletin edited by Alice Henkel and published by the Bureau of Plant Industry of the United States Department of Agriculture.

Black Cohosh (*Cimicifuga racemosa*), also known locally as black snakeroot, bugbane, bugwort, rattlesnake root, rattleroot, rattletop, richweed and squawroot. It grows in the shaded woodlands from Maine to Wisconsin and south to Georgia and west to Missouri. The Indians long regarded the root as a valuable medicinal plant, not only for the treatment of snake bites, but it was also a very popular remedy among their women, and it is to-day esteemed as an alterative, emmenagogue and sedative. It is officially listed in the United States Pharmacopeia.

Blue Cohosh (*Caulophyllum thalictroides*), also known locally as papoose root, blueberry root, blue ginseng, yellow ginseng. The dried root is the part used in medicine as a demulcent, antispasmodic, emmenagogue and diuretic. Snakeroot (*Asarum canadensis*), also called wild ginger, Indian ginger, Vermont snakeroot, heart-snakeroot, southern snakeroot, colt's foot, broadleaved asarabacca, colic root, etc. The root is used as an aromatic, diaphoretic and carminative. Serpentaria, also known locally as snakeweed, pelican-flower, sangrel, sangree-

root, etc., grows in rich woods from Connecticut to Michigan and certain varieties occur in the southwestern States. The roots are used for their stimulant, tonic and diaphoretic properties. It is officially listed in the United States Pharmacopeia. May-apple (*Podophyllum peltatum*), also locally named mandrake, wild lemon, ground-lemon, hog-apple, raccoon-berry, duck's foot, umbrella-plant, vegetable calomel, etc. It grows all over the eastern half of North America. The root is used as an active cathartic and is official in the United States Pharmacopeia. Pokeweed (*Phytolacca decandra*), also commonly called poke, pigeon-berry, garget, scoke, pocan, coakum, inkberry, American nightshade, cancer-jalap, redweed, etc., is found in rich soils along fence rows and on unimproved land from Maine to Minnesota and south to Texas. The root is used for its alterative properties in treating various diseases of the skin and blood, and in certain cases in relieving pain and allaying inflammation. It also acts upon the bowels and causes vomiting. The matured berries are also used in medicine. Seneca snakeroot (*Polygala senega*) or mountain flax, the root, once used by the Indians as a cure for snakebite, is now employed as an expectorant, emetic and diuretic. Lady's Slipper (*Cyripedium hirsutum Mill*), or moccasin-flower, nerve-root, male nervine, umbril root, etc., rootstock and roots are used in medicine as a nerve tonic and an antispasmodic, also for the same purposes as valerian. Bethroot (*Trillium erectum L.*), birthroot, bathwort red wake-robin, bumblebee-root, dishcloth, Indian shamrock, wood-lily, etc. Root used in medicine as an astringent, tonic, alterative and expectorant. Culver's Root (*Leptandra virginica*) or black-root, speedwell, tall veronica, wholywort; rootstock and roots used as an alterative, cathartic and in disorders of the liver. Stone root (*Collinsonia canadensis*), or knobroot, horsebalm, richweed, ox-balm, citronella; root used for its tonic, astringent, diuretic and diaphoretic properties. Leaves are also used as an application to bruises. Crawley-Root (*Corallorhiza odontorhiza*) or coral root, dragon's claw, chicken toe, fever root; root used to promote perspiration and also as a sedative and in fever. Male fern (*Aspidium*) or sweet brake, basket-fern, etc.; root used as a remedy for worms. Care must be taken to avoid overdoses which are highly dangerous. Goldthread (*Coptis trifolia*) or cankerroot, mouthroot, etc.; root used as a remedy for ulcerated and sore mouth; also as a wash or gargle for similar affections and as a bitter tonic. Twinleaf (*Jeffersonia diphylla*) or rheumatism root, helmet pod, ground-squirrel pea, etc.; rootstock used as a diuretic, alterative, antispasmodic, and a stimulating diaphoretic. Large doses are emetic. Canada moonseed (*Menispermum canadense*), or yellow sarsaparilla, vine-maple, etc.; both roots and rootstock are used in medicine as a tonic, alterative, and diuretic. Wild turnip (*Arum triphyllum*), or wild pepper, devil's ear, starchwort, priest's pintle, etc.; the partially dried corn is used as a stimulant, diaphoretic, expectorant and irritant. Black Indian hemp (*Apocynum cannabinum*), bowman's root, wild cotton, etc.; root has emetic cathartic, diaphoretic, expectorant and diuretic properties, and is much used in dropsical affections. Chamælirium or Helonias (*C. luteum*), or unicorn root, drooping starwort, devil's bit, etc.; of especial use in derangements of women. Wild Yam (*Dioscorea villosa*), or colic root, devil's bones; root is said to possess expectorant properties and to promote perspiration, and in large doses providing emetic. It is sometimes used in bilious colic. Skunk-cabbage (*Dracontium fœtidum*), or polecatweed, collard, stinking poke, etc.; rootstock is used in affections of the respiratory organs, in nervous disorders, rheumatism and dropsical complaints. American Hellebore (*Veratrum viride*), or bear-corn, bug-bane, earth-gall, itchweed, etc.; it is an acrid narcotic poison, and has emetic, diaphoretic and sedative properties. Other medicinal plants with their specific uses in medicine are: Water-eryngo (diuretic, expectorant); yellow jasmine or jessamine (powerful effect on nervous system); sweet flag (aromatic stimulant and tonic in feeble digestion; dried root chewed for dyspepsia); blue flag (alterative, diuretic and purgative); cranes-bill (tonic and astringent); dandelion (tonic in diseases of the liver and in dyspepsia); soapwort (tonic, alterative, diaphoretic); burdock (alterative in blood and skin diseases); yellow dock (purifier of blood and in the treatment of skin diseases); stillingia, or queen's root, nettle-potato, etc. (alterative); American colombo, or yellow gentian, ground century, etc. (simple tonic, emetic and cathartic); couch-grass, quitch-grass, etc. (fluid extract used in affections of the kidney and bladder); echinacea, or coneflower, nigger-head (alterative and to promote perspiration); aletris, or stargrass, starwort, aloe-root, husk-wort, etc. (of value in digestive affections); wild indigo, or yellow broom, shoofly, etc. (emetic and cathartic in large doses; stimulant, astringent and antiseptic; and as a local application to sores, ulcers, etc.); pleurisy-root (used in disordered digestion and in affections of the lungs to promote expectoration and induce easier breathing); bloodroot, coon root, yellow puccoon, tetterwort, turmeric, etc. (tonic, alterative, emetic and stimulant); pinkroot, or star-bloom, wormweed (principal use is as an anthelmintic); Indian physic or false ipecac (emetic); wild sarsaparilla, shadbush, wild licorice (alterative, stimulant and diaphoretic); comfrey, or bruisewort, gumplant, slippery-root (used in coughs and diarrheal complaints; action is slightly astringent and demulcent); elecampane, or horseheal, elfwort, velvet-dock, wild sunflower (used in affections of the respiratory organs, in digestive and liver disorders, catarrhal discharges and skin diseases); queen of the meadow, or boneset, motherwort, quill-wort, etc. (astringent and diuretic); hydrangea, or seven-barks (as a diuretic and in calculous complaints); Oregon grape, or holly-leaf barberry (tonic and blood purifier, berries in preserves and cooling drinks). Ginseng (roots exported to China, where they are reported to be used as an almost universal remedy. Odd-shaped roots are said to be especially prized as talismans. Many other plants are used in limited quantities, among which are black birch bark, blackberry, catnip, chicory, corn ergot or smut, geranium, hemlock, huckleberry, penny-royal, peppermint, sheep laurel, tag alder, water pepper, wintergreen, witchhazel, etc.

PLANTS, Migration of. Plants need a constant change of situation because they may exhaust the amount of the special food of each species in the soil; or impart to that soil injurious elements; or for the sake of increased vigor. They accomplish the needed change by many methods. Very low forms, such as the molds, spread by a creeping action; some higher plants are torn up by the roots and rolled long distances, to survive and renew their fixture and growth when favorable conditions are reached. Those that have "runners," like the strawberry, reach out, take root at a distance and so advance by long steps, as it were; while the grasses, ferns and others make similar progress by means of underground root-stems. Dissemination is accomplished more generally, however, by means of fruit (seeds). In many cases the seed-pods are so strained by ripening that at last they burst, hurling the seeds to a considerable distance, or the pods open and the seeds are tossed out by some agitation of the plant, usually with elastic force. No sort of this machinery, however, advances the plant-species more than a few feet; and far more effective is dispersal by wind and water. To this end seeds of a large variety of trees and herbs are provided with wings, like those of the maple and tulip-tree, or with long feathery attachments, like cotton and dandelion, which serve as parachutes to sustain them in the air while wafted away to new habitats. These windblown seeds are always minute and oily, the latter feature giving them the necessary lightness of weight. Floating is a means of dispersal important not only to aquatic plants, but to others. Many river and pond-plants move bodily and are carried here and there by currents; and floods often transport living land-plants to new regions. Some send abroad regenerative parts, as buds; or, in more cases, seeds in capsules or little bladders, or air-tight pods. The wide distribution of the cocoanut palms throughout the tropics is due to the ability of the tight nut to float long distances. Mangrove seeds are especially fitted to do so; and that a great many other land-growing trees and plants can make long voyages, as seeds, is shown by the vegetation clothing remote islands and the way in which island floras are related to prevailing oceanic currents. That animals assist plants to migrate is well known. Many seeds are provided with hooks that catch in hair and wool and are carried onward by passing animals. Birds and mammals eat fruit and drop the uninjured seeds perhaps miles away. The planting of nuts by squirrels, jays and so forth, is useful in this direction. Finally, man has been distributing plants by his operations ever since he began to move about, by the use of fruit and seeds for food, by passing them on for new orchards and grainfields from country to country; and also by the accidental carriage of them in his ships and otherwise. Every country now has many introduced species. See PLANT GEOGRAPHY.

PLANTS, Morphological Evolution of. The distinction of all living things into plants and animals seems on first thought to be an easy one to make. Animals walk or fly or swim, have mouths by which they eat food and stomachs in which to digest it; they have eyes with which to see, ears to hear, etc.; while plants are firmly fixed by their roots, have no power of motion, take their food from the air and dissolved in water from the soil and have in the common view no power of perception of light, sound, etc. The foregoing distinctions are true if we confine our attention solely to the higher groups of plants and animals. But when we follow downward from the more complex to the simpler plants and animals we find that we are converging more and more until we reach some groups of organisms which have been claimed by both botanists and zoologists. It is impossible to deny that some of these have almost equal right in either kingdom, so that any line that may be drawn to separate animals and plants must be arbitrary. On the other hand many forms that were once considered to be plants are certainly animals, e.g., sponges, corals (*Bryozoans*), while such a group as the slime molds (*Myxomyceteæ or Mycetozoa*), still regarded as belonging to the plants by most botanists, in reality seems to show phylogenetic kinship only with the animals and so ought to be placed there. There still remain, however, certain groups which cannot be looked upon as other than transitions from animals to plants or plants to animals. It is for these transitional groups that it is especially difficult or absolutely impossible to draw a natural line of separation between the two kingdoms. The organisms in question include the *Flagellata* (in the wider sense of the term) and the related *Volvocales* (often included in the *Flagellata*) and the *Peridiniales* (or *Dinoflagelata*). These are in part colorless organisms, but many of them are green and contain chlorophyll by means of which they manufacture food in the same manner as undoubted plants. They are, however, motile during their chief vegetative period, non-motile and encysted only during rest periods. In the latter stages they are very similar to the ordinary vegetative stage of many undoubted plants belonging to the order *Chlorococcales*, in which during reproduction motile, naked cells are formed that are scarcely distinguishable from the vegetative stages of the organisms under question. Any line drawn will be arbitrary: perhaps the most logical procedure, then, is to consider as animals those forms in which the motile, usually naked stage is predominant, with the non-motile, encysted stage serving merely to tide the organisms over until favorable conditions again occur, while those forms are to be called plants in which the ordinary vegetative stage is non-motile and only the reproductive stages motile. The foregoing distinctions must, of course, be understood to apply only to those debatable groups which have most of their other characters in common. The sponges are motile only during their reproductive stages, but in their other

characters they are animal so that this rule would not apply, while the motile diatoms like *Navicula* are so plantlike in other features that they would also not be affected.

With the forgoing in view we may consider the stages of evolution in plants. In so doing it must be remembered that the first plants came into existence eons ago and that it is impossible to be certain just what they looked like or what was the early course of their evolution. Judging by the simplest plants now known these first plants must have been naked, without any hard parts to be preserved as fossils. Hence the earlier rocks carry very few remains that can be with certainty ascribed to the simpler plants, it being only in the most recent rocks that some of the softer aquatic forms are recognizable, although it seems certain that for ages the only plants in existence were water plants. Accordingly we must have recourse to the now existing forms of these simpler plants, making the perhaps not unwarranted assumption that they represent, as it were, stragglers along the line of evolutionary advance whose progress has been slow, so that although they are descendants of those primitive plants of ages ago yet they have changed but little in this long period of time. By this method the main lines of evolution may perhaps be indicated with a fair probability of correctness, but it will perhaps always be impossible to clear up the details to such a degree as has been done in the study of the ancestry of the horse and other animals which having hard skeletons have left permanent records in the rocks.

The simplest plants now known are some of the bacteria and the one-celled blue-green algæ (*Chroococcus,* etc.). There is no serious doubt that the bacteria and the blue-green algæ are closely related; which are the oldest, however, is a question that offers many difficulties and that seems beyond our present powers of solution. Most bacteria are unable to grow without the presence of some organic matter while the chlorophyll-containing algæ are independent in that they can manufacture their own organic matter from inorganic substances. Thus *a priori* they would seem to be more primitive. Yet, on the other hand, there are a few bacteria which if supplied with ammonia or nitrites are able to make use of CO_2 without the need of light or of chlorophyll and thus build up their necessary organic compounds. It is here assumed, however, that the bacteria are not primitive but derived from the blue-green algæ.

These most primitive plants that we know, e.g., *Chroococcus,* consist of minute balls of protoplasm colored bluish green and enclosed in a thin wall made up in part of chitin. The central, uncolored part of the protoplasm probably functions as a nucleus or directive centre for the plant, but is not set off distinctly from the rest of the cell as is the case in the higher plants. Neither is the coloring matter located in definite organs of the cell, the chloroplasts, but merely scattered throughout the outer part of the protoplasm. Reproduction, also, is simple, consisting of the division of the cell into two cells which soon separate. The next step in evolution seems to have been that of the adherence of these cells for some time after division, resulting in the formation of irregular colonies. As the successive directions of division became more and more fixed these colonies came to have more and more definite shape, square plates, cubes, hollow spheres, etc., the furthest advance seemingly having occurred in the formation of filamentous colonies. In these the successive planes of division are all in the same direction. In *Oscillatoria* and its near relatives the cells of the filament are all alike, but in the somewhat higher forms such as *Nostoc,* certain cells are enlarged (heterocysts). A further type of cell differentiation is seen in *Rivularia* and its relatives in which the basal cell is a heterocyst and attached to some object, the next cells being large, those further out gradually diminishing in size until the ultimate cells are very long and slender or even pointed.

The bacteria are considered as an offshoot from plants related to *Oscillatoria* (e.g. *Phormidium*), the chief difference between such blue-green algæ and the higher bacteria such as *Beggiatoa* lying in the presence of the coloring matter in the former and its absence in the latter. The mode of growth and of reproduction are the same. From *Beggiatoa* the gradation is gradual throughout the filamentous bacteria and down to the one-celled forms that constitute the commonest forms of bacteria. Yet it is not certain that this line is continuous, for flagella, which are apparently lacking in the blue-green algæ and *Beggiatoa* are present in many of the one-celled bacteria. Possibly this indicates an origin of the latter independent of that of the filamentous bacteria.

All of the foregoing forms are placed in the Phylum *Myxophyceæ.* There remains a small group of plants placed by some botanists in this and by others in other phyla that are possibly a transition to the next phylum. These plants (*Glaucocystis,* for example) are blue-green, like the others, and multiply by division of the cells, but differ in the possession of a definite nucleus cut off from the remainder of the cell by a nuclear membrane, and in the restriction of the coloring matter to definite organs, the chloroplasts.

In the next phylum, Chlorophyceæ, the coloring matter is bright green, instead of blue-green, and is mostly, if not always, confined to definite chloroplasts, usually large and few in number in the cell. The nucleus, moreover, possess a definite membrane and is well organized. The cell wall is composed of cellulose or carbohydrates of kindred nature. Multiplication by simple division of the cell is not the sole method of reproduction except in a few forms, such as Protococcus. On the contrary we find that two great advances have taken place in the reproductive methods in this phylum. The first is the production of zoospores. The contents of a vegetative cell, or, in a few of the more specialized forms, of a special cell, divide up within the wall into a number of naked cells provided with long flagella, or swimming organs, by means of which after emerging from an opening in the cell wall the zoospores (as these naked swimming cells are called) swim around. After a while they settle down, form a cell wall and start the new plant. The second great advance is the introduction of sexual reproduction. This seems to have been at first a modification of the foregoing method, for in some of the more primitive forms of this phylum, e.g., *Ulothrix,* cer-

tain swimming cells act merely as zoospores under some external conditions while under other conditions the naked cells fuse by pairs, not merely the cytoplasm but also the two nuclei undergoing fusion. In the more highly developed members of this phylum we find the two functions entirely separated so that the cells that function sexually are entirely distinct from those that act as zoospores for the asexual reproduction of the plant. In this first appearance of sexuality it is noteworthy that sexual reproduction occurs in plants (and the same is true for animals) before there is any distinction of sex.

In this phylum as in the Phylum *Myxophyceæ* we find two tendencies exhibiting themselves in the vegetative structure, viz., the formation of plants consisting of single cells or regular or irregular colonies of cells (Class *Protococcoideæ*) and that of plants consisting of simple or branched filaments or rarely sheets or tubes (Class *Confervoideæ*). In the more highly developed members of the latter class we find that the sexual reproduction has undergone a further evolution. Instead of producing sexual cells that are all alike these plants produce two kinds of gametes, smaller, very actively motile sperms, usually arising in large numbers, and larger, less numerous, sluggish eggs. This is the beginning of the differentiation of sex. The further development along this line of evolution led to the complete loss of motility by these eggs and their retention, for further protection, within the walls of the mother cell (the oogone) where the sperm seeks them out and fertilizes them, entering through some sort of an opening in the cell wall. The height of evolution in this direction in this phylum is reached in *Coleochæte,* in which the fertilized egg becomes surrounded by an investing layer of protective filaments which makes its safety doubly sure.

Closely allied to the one-celled green slimes (Class *Protococcoideæ*) are those organisms mentioned before, whose assignment to the animal kingdom or vegetable kingdom is a matter of rather arbitrary choice. A form like *Chlamydomonas* is to all intents and purposes a permanently motile zoopore which loses its flagella and becomes invested with a firm cell wall only to enable it to survive unfavorable conditions. In mode of reproduction and in structure it clearly approaches on the one hand such an undoubted plant as *Chlorococcum* and on the other certain of the *Flagellata* whose kinship to the rest of the animal kingdom is incontestible.

From the simpler, filamentous *Chlorophyceæ* appear to have arisen the conjugate algæ phylum (*Zygophyceæ*), whose more primitive forms are filaments made up of uninucleate cells with green chloroplasts. The power of producing motile zoospores has become lost and sexual reproduction takes place by the union of the non-flagellate protoplasmic contents of adjacent cells, usually of neighboring filaments, rarely within the same filament. By a further differentiation of the cells and organization of the cell wall into two distinct pieces we find the desmids (Order *Desmidiales*) arising. In this order the filamentous condition of the more primitive forms soon becomes lost as the filaments become more and more constricted at the joints, until in the highest genera the filaments are very few celled or even more often reduced to single cells. The diatoms (Class *Bacillarioidcæ*) with their silicified walls and their brown-colored chloroplasts appear to be related to the desmids, to the filamentous forms of which they show the nearest resemblance, especially if the filamentous diatoms are selected in making the comparison. In parallel development we find the gradual shortening of the cells of the filament in each order and the eventual breaking up of the filaments into one-celled forms, exactly as happened in the desmids.

Again going back to the simpler filamentous *Chlorophyceæ* we find another group (phylum *Siphonophyceæ*) arising. The evolutionary tendency in this case has been along the line of cœnocyte development, the rather short, uninucleate cells of the *Chlorophyceæ* giving way to longer, multinucleate cœnocytes with septa at occasional intervals (*Cladophora*) and finally to tubular cœnocytes almost completely lacking cross walls. In the simpler forms the asexual reproduction by zoospores and sexual reproduction by the union of equal motile gametes resembles very closely that of the simpler *Chlorophyceæ,* but, as in that phylum, the higher groups show, first inequality of gametes, both retaining motility, and finally the complete loss of motility on the part of the female gamete which is retained within its mother cell wall, as in *Vaucheria.* From plants clearly very close to this last have arisen a large number of genera and species of chlorophyll-less forms comprising the class *Phycomyceteæ.* Vegetatively these resemble *Vaucheria* and its nearest relatives in consisting of branching, non-septate, tubular cœnocytes, the chief point of difference being the lack of chlorophyll. This necessitates a different mode of life, either saprophytic, i.e., feeding on dead organic matter, or parasitic upon animals or more often plants. As to asexual reproduction that, in the lower *Phycomyceteæ* is by means of zoospores while sexual reproduction is by means of motile sperms which seek out the non-motile egg within its oogone. In most members of this class, however, evolution has gone a step further and made fertilization less a matter of chance by developing a tube which leads from the antherid into the oogone, so that there is no opportunity for the sperm or at least its nucleus to fail to reach the egg. These colorless plants are aquatic, like their green ancestral forms, in the more primitive groups (*Saprolegniales*), but in the downy mildews (*Peronosporales*) we find that they have emerged and become parasitic in higher plants. Having ceased to be aquatic they did not at once cease to produce zoospores in the course of their life cycles. However, the zoosporangia became reduced in size and instead of setting the zoospores free while still attached to the plant, the zoosporangia themselves are set free to be scattered by the wind, producing the zoospores only when they fall into a drop of water. In two genera of the group there is one step further that has been taken in that the zoosporangia fail to produce zoospores at all and germinate directly.

In the black molds (*Mucorales*) the evolution proceeded differently. Evidently this group also arose from the aquatic *Saprolegniales,* but as the fungi emerged from the water and be-

Evonymus curopaea

alpinum

Rhodoleia Champion

Callistemon angustifolia

Alloplectus peltatus

Salvia sclarea

came terrestrial the zoosporangia became larger instead of smaller and did not set their contents free as naked zoospores but permitted these to become encysted before they were set free to be scattered by the wind. In this group a few genera show a rapid reduction of size of these large sporangia until some forms are known in which, as in the preceding group, the sporangium is reduced to a small, wind-distributed body or conidium.

The *Chlorophyceæ* appear to have been a very prolific group for the production of other phyla. So in still another direction we find arising the brown algæ (*Phylum Phæophyceæ*), whose primitive filamentous forms reproduce asexually by zoospores and sexually by the union of equal motile gametes. In this phylum the vegetative structure has undergone the greatest evolutionary advance among all the lower plants. From simple filaments of cells to the massive kelps or complicated rockweeds or sargassums there is almost an unbroken series. Except for some of the largest trees the biggest plants in the world are the giant kelps (*Nereocystis*) of the north Pacific Ocean, some of which attain a length of several hundred feet with stems several inches in thickness. Along with this external differentiation we find tissue differentiations to a higher degree than in any other plants outside of the so-called "vascular" plants, which are very much further developed evolutionally. On the other hand the reproductive processes are but little modified. Asexual reproduction by means of zoospores persists in most of the forms, although lacking in some of the higher members of the phylum. Sexual reproduction consists of the union of equal motile gametes in the lower forms, of unequal motile gametes in those a little further advanced, and in the union of motile sperms of small size with large, non-motile eggs in the highest forms. In all cases the union occurs outside of the parent plant and the product of the union is a simple cell which by its division produces the new plant.

The great phylum of the red seaweeds (*Rhodophyceæ*) probably also had its roots in the *Chlorophyceæ*, but so many intermediate forms have been lost that it is difficult to imagine just how to picture the steps along which the evolution progressed. The simplest red seaweeds consist of unbranched or branched filaments of uninucleate cells, with their chloroplasts stained red or violet. Motile reproductive cells are totally lacking in the group, barring a possible amœboid motion observed in a few cases. Asexual reproduction consists of the production of non-ciliate cells, either singly or in fours (monospores and tetraspores, respectively), these escaping from their walls as naked protoplasts which are carried about by the water currents. Sexually, an egg, enclosed in an oogone, is fertilized by a naked-non-motile sperm which is carried by the currents and which clings to a projection of the oogone, the trichogyne. The sperm nucleus enters this projection and passes downward to the egg nucleus with which it unites. Now, unlike the forms hitherto under discussion, the fertilized egg undergoes rapid nuclear division and ultimately branches out into several or many filaments which terminate in the ultimate reproductive cells, the carpospores. Thus one sexual union results in the production of numerous reproductive cells instead of one. In the higher red seaweeds the carpospores give rise to plants which produce only the asexual tetraspores, while the plants arising from these tetraspores are, in turn, the sexual plants, thus introducing a new feature, the "Alternation of Generations" (q.v.). It is worthy of note that this feature appears to have arisen at various points in the vegetable kingdom independently. Aside from this complexity of reproductive processes the red seaweeds show all gradations within the group from simple filaments to very complex, massive bodies. Like the brown seaweeds they are prevailingly marine.

The red seaweeds are of interest, because from them seems to have arisen the great group of the higher fungi phylum (*Carpomyceteæ*) just as the lower fungi (*Phycomyceteæ*) arose within another phylum (the *Siphonophyceæ*). The fungi in question are filamentous and largely terrestrial, often parasitic upon plants or even animals. They lack chlorophyll, but in many ways show structural characters found also in the *Rhodophyceæ*. Asexual reproduction is by the production of non-motile conidia. The more primitive forms have a form of sexual reproduction that resembles greatly the process in the red seaweeds, viz., the union of a non-motile, water-borne sperm with an extension of the oogone, the result of the union being the development of an extensive mass of threads which terminate in the reproductive cells. These terminal reproductive cells are different in the three great classes of this phylum, being an ascus, containing usually eight spores, in the *Ascomyceteæ*, a basidium, producing externally usually four spores, in the *Basidiomyceteæ*, and a teliospore, producing a usually four-celled promycelium, which gives rise to four spores, in the *Teliosporeæ*. In this phylum we find that the sexual process has undergone several modifications as we pass from the more primitive to the more highly-developed groups. Thus the formation of separate sperm cells is omitted and the antherid and oogone (or its extension, the trichogyne) come in immediate contact. Finally antherids seem to be wholly omitted, the sexual process in such plants consisting in the union of what were potentially egg nuclei or their derivatives. In many fungi even the oogones fail to be produced, the nuclei that eventually unite being apparently of vegetative origin. Throughout the phylum the vegetative structure maintains its simplicity, consisting essentially of a more or less loose weft of branching, septate threads. It is the reproductive structures that show the greatest differentiation. Thus, one finds in this group such varied structures as the cup-like apothecia of the cup fungi, the globose, subterranean fruit of the truffle, the umbrella-formed mushroom, the bracket-like pore fungus, etc.

One of the most significant steps in the evolution of plants resulted in the development of the liverworts and mosses phylum (*Bryophyta*). This is the first group of chlorophyll-bearing plants to become terrestrial, although even in the first phylum (the *Myxophyceæ*) a few forms crept out on land to inhabit damp places. The plant body is mostly more compact than in the more or less filamentous *Chlorophyceæ*, which were probably the ancestors of this group. They are attached to the soil by

rhizoids which serve not only to hold the plant in place but also to absorb water and pass it on to the plant. Their aquatic ancestry is still shown by the production of motile sperms which are dependent upon the presence of water at the proper time to enable them to swim to the egg. Another forward step is seen in the fact that the eggs are surrounded before fertilization by a protective layer of cells, forming a flask-shaped structure, the archegone. Unlike the lower *Chlorophyceæ,* the fertilized egg in this phylum does not become a thick-walled oospore but divides rapidly, forming a complex structure, rooted in the parent plant from which it draws a large part of its food, that produces internally the ultimate reproductive spores. The plant body likewise shows evolutionary development from a flat thallus in the lower liverworts, becoming lobed in those higher in the scale, and finally reaching the leafy-stemmed mosses.

In the next step, which probably took place rather rapidly, the relative importance of the sexual stage (*gametophyte*) and of the spore-bearing stage (*sporophyte*) has been reversed. As in the *Bryophyta,* the sporophyte starts as a single fertilized egg cell within an archegone. This egg divides repeatedly to form a many-celled structure which is at first enclosed within and dependent upon the gametophyte. Soon, however, it acquires its own roots and leaves and quickly becomes entirely independent of the gametophyte, which dies, leaving the sporophyte as the long-lived stage. This is the step of evolution that has been reached by three phyla, *Pteridophyta, Calamophyta* and *Lepidophyta.* These differ markedly from one another in the structure of the stem, leaves and spore-bearing organs, but the fundamental life history is the same, at least in the lower representatives of each group. By an apparently parallel development each of the three groups has taken a further but similar step, in that the spores produced are of two kinds, which produce respectively male or female gametophytes. These sexual plants are much smaller in size and depend for their food largely upon the food stored up in the spores themselves, instead of manufacturing it in large amounts, as in the mosses and liverworts or the lower members of these same phyla. This line of evolution is carried one step further in the phylum *Cycadophyta* (sago palms and their relatives), where the spores that produce the female sexual plants are permanently retained within the parent plant, undergoing their development there, including the formation of egg, fertilization of the latter and the beginning of the development of the new sporophyte generation. The resulting structure, consisting of the spore-containing organ (the sporangium), containing the remains of the female gametophyte, which in its turn contains the new sporophyte generation, is what is called a seed. In this phylum the aquatic ancestry is still revealed in the production by the much reduced male gametophyte of motile sperms which accomplish the fertilization of the eggs.

The last developed phyla in the vegetable kingdom retain the chief characters of the last-mentioned phylum. In them, however, the sperms are no longer provided with cilia or flagella by means of which they swim a short distance from the ruptured tip of the male gametophyte to the archegones containing the eggs. The male gametophytes themselves grow as long tubes down through the intervening tissues and spaces directly to the egg, only there rupturing to permit the sperm to accomplish its function. In one of these phyla (*Strobilophyta,* the conifers) the reproductive structures are chiefly arranged in cones with the seeds produced on their open surfaces. The highest development is found in the other phylum (*Anthophyta,* the flowering plants), where the seeds are enlosed within special structures, the pistils, thus attaining a maximum of protection. Vegetatively it is noteworthy that the sporophyte, which from the *Pteridophyta* (ferns) onward is the long-lived structure, becomes more and more complex in its external and internal structure, thus reaching its culmination in the *Anthophyta,* whose tissues as well as general structure are differentiated further than in any other group of plants. Within this group the plants vary from the minute duckweeds, only a few millimeters in dimensions, to the tall eucalyptus trees, towering 400 feet into the air, from annuals that live but a few short weeks and then lie dormant as seeds until favorable conditions again appear, to trees that may live for many centuries, from submerged aquatic inhabitants of rapidly-flowing streams to the spiny, leafless cacti of the deserts. And yet throughout this group the one structure, the flower, holds them all together in a common bond of kinship, and through this structure we can trace backward the steps of evolution until we again find the minute microscopic sexless plants that seem to represent most nearly the first plants that arose, eons ago, in the water or mud of the primeval sea.

ERNST A. BESSEY,

Professor of Botany, Michigan Agricultural College.

PLANTS, Ornamental. The climate and soil of North America vary so tremendously that only by a close study of local florists' catalogues, and the reports of State experiment stations, can the ornamental plants suitable for any given locality be determined. A hint of the trees, shrubs, climbers, aquatics and lesser herbaceous plants, of the perennial type, most frequently set out, is given below.

Rapidly-growing trees, particularly for treeless regions, are the cottonwoods (*Populus*) common along mid-western water courses; the silver maple (*Acer*) and the white willow (*Salix*) for moist soils: white and Scotch pines (*Pinus*) for sandy ones: white and Norway spruces (*Picea*); green ashes (*Fraxinus*); osage orange (*Toxylon*); European larch (*Larix*); black locust (*Robinia*); hardy catalpa (*Catalpa*) and Russian mulberry (*Morus*) are recommended for planting, serving as windbreaks, as shade trees and as material for fence posts and fuel.

For street planting in city and village, certain trees have been found more or less resistant to the deleterious effects of urban existence. The most important of these are the plane-tree of Europe (*Platanus*) readily identified in winter by its long-hanging balls of fruit; the trim maples (*Acer*) the leaves of some species turning to gorgeous color in fall; graceful elms

(*Ulmus*) arching over roadways, wherever they can be protected from noxious insects; the tree-of-Heaven (*Ailanthus*), evil-smelling when in bloom, but gay later with huge bunches of pinkish fruits, half-hidden in the compound foliage of this most enduring of all these trees. Rather less common are the Japanese Gingko, a conifer which sheds its fan-shaped foliage in winter; ashes (*Fraxinus*) untroubled by insects; shapely lindens (*Tilia*), fragrant in bloom and humming with nectar-seeking bees, and occasionally other trees like slowly-growing oaks (*Quercus*) and Liriodendrons. Lombardy poplars (*Populus*) and bald cypress (*Taxodium*) are planted for formal gardens; tall, slender and conical they also make good deciduous screens. Coniferous evergreens are planted moreover for screens as well as for windbreaks and ornament, especially the spruces (*Picea*); pines (*Pinus*); firs (*Abies*), and hemlocks (*Tsuga*). Sombre, thick-foliaged cedars (*Juniperus*), Chamæcy-paris, and arbor-vitæ (*Thuya*), lend themselves to architectural effects, being symmetrical of growth; they are frequently set and trimmed for hedges, taking the place of the old-time slowly-growing yew (*Taxus*) and box (*Buxus*). Privet (*Ligustrum*) is also used much for quickly-growing hedges; also barberries (*Berberis*) brilliant in autumn with arching sprays loaded with oval scarlet berries; the even more interesting holly (*Ilex*); thorns (*Cratægus*), handsome both in flower and fruit; the glossy osage orange (*Toxylon*), and honey-locust (*Gleditsia*), the latter being sufficiently armed with spines Japanese quince (*Cydonia*), flowering gayly, is used for low hedges. The Southwest has thickets of cactus, impressed for impenetrable spiny hedge-rows.

On lawns and in gardens are planted beeches (*Fagus*) some varieties having purple leaves; the "silver-vested birch" (*Betula*) most interesting in its weeping forms; the weeping willows (*Salix*) and Camperdown elms (*Ulmus*) with other "weeping" forms of different trees; sumachs (*Rhus*) holding up their pyramids of scarlet velvety fruit all winter; mountain ash (*Sorbus*), the rowans of Scotland, attractive to all birds when adorned with its bunches of red berries, and repellant to witches if such be about; honey-locust (*Gleditsia*) prodigal of thorns, and of heavy pods filled with sweet pulp hanging amid the delicate compound foliage of the flattened top. These are more conspicuous for foliage and form than for their flowers, but there are a number of available flowering trees. That locust (*Robinia pseudacacia*) called "acacia" in Europe, covers itself with masses of white fragrant pea-blossoms as the compound leaves appear, yielding much honey to bees; even earlier bloom the purple flowers of the Japanese Paulowina, on naked stems, like those of the Sophora, from the same country, which blooms much later, but is scarcely hardy north of New York; and those of the gay redbud (*Cercis*), as well as the white tassels of the shadbush (*Amelanchier*) and the great snowy bracts of dogwood (*Cornus*). Japan sends some of the most exquisite flowering plums and cherries, scarcely more beautiful, however, and not as fragrant as the native flowering crabs (*Pyrus*). Yellow wood (*Cladrastis*), the fringe tree (*Chionanthus*) and the silver bell tree (*Halesia*) are native white flowering trees of much value for small places. Indian bean trees (*Catalpa*) although of Southern origin are frequently seen in Northern parks, where their great panicles of white, streaked, velvety flowers are set off by the huge heart-shaped leaves. The catalpa is apt to be irregular, even sprawling in habit, but the familiar horse-chestnut (*Æsculus*) and its American relatives the buckeyes, are singularly symmetrical in growth, and the former has striking flower-spires of white.

In warmer climes we find live oaks (*Quercus*) dripping with Spanish moss; palms — Washington, Royal, Phœnix and Monterey, and near the coast palmettoes and cocoanuts; Australian eucalyptus, tall with strangely-set foliage and tasseled flowers; handsome liquid-ambar with star-shaped leaves that turn to red and purple in the fall; the pleasant-fruited pecan (*Hicoria*); mulberries (*Morus*) whose soft fruit is so attractive to birds that the tree is sometimes planted to allure them from more valuable fruits, and luscious figs (*Ficus*). The Pride-of-China tree (*Melia*) is another favorite food-tree of birds who are said to occasionally intoxicate themselves with its rather poisonous translucent berries. Pepper trees (*Schinus*) and the madrona (*Arbutus*) laden with scarlet berries, are also frequented by birds. The crape myrtle (*Lagerstræmia*) with crinkled petals of rose and white, the blazing royal poinciana (*Poinciana*); the handsome golden-flowered Cassia fistula; the whole tribe of wattles (*Acacia*) including the fragrant-flowered cassie (*A. farnesiana*); the fern-leaved silk-oak (*Grevillea*) and the weird she-oak (*Casuarina*) are well-known exotics frequently planted. Among the natives are the blue-flowered California lilac (*Ceanothus*), the magnificent magnolias and the loblolly bay (*Gordonia*).

The South, again, can have a wonderful collection of flowering shrubs, both native and foreign, some of which are cultivated in the window gardens and greenhouses of the North. Such are the oleander (*Nerium*) bearing great sprays of pink or white or cream flowers; Chinese Hibiscus, or shoe-black plant, tossing its gay flowers with long projecting column out of every shrubbery; the pomegranate (*Punica*), its flowers of pure vermilion followed by heavy fruit that pulls down the slender branches; golden Allamandas, half-climbing in habit, azure phlox-like Plumbago; stiff waxen Ixoras of many hues, the scentless Camellias, and all those shrubs of different families called jessamine, scented and white and waxen of petals. One is the Cape jessamine better known at the North as Gardenia; another is the crape jessamine (*Tabernæmontana*) the rose-bay of India; still another is the Confederate jasmine (*Trachylospermum*) with delightful flowers like tiny children's windmills. Among native shrubs are the Stuartia with large white flowers; the lovely Matilija poppy (*Romneya*); Bauhinias, with orchid-like flowers, gorgeous Lantanas; the sea-side mahoe (*Paritium*), with effective yellow flowers like hollyhocks; Daturas with huge white nodding trumpets and many others.

The calico bush (*Manzanita*) thickly bedecked with fragrant white bells (*Arctostaphylos*) also noted for the rich color of bark and

twigs; the extraordinary tree-yuccas (*Yucca*); Californian holly (*Heteromeles*), whose cardinal-berried sprays are used for Christmas decoration; that barberry (*Berberis*), with holly-like foliage, called most frequently Mahonia; the golden-flowered Fremontia; the tree-mallow (*Lavatera*); the tasseled Garrya; and the fragrant California laurel (*Umbellularia*) are often seen in Western and Pacific Coast plantations.

There is, however, no lack of flowering or fruiting shrubs for the more severe climates, and a certain amount of garden-color may be procured for even the dreary winter season, by planting broad-leaved evergreens, such as the stiff formal box (*Buxus*); hollies (*Ilex*); mountain laurel (*Kalmia*) and Rhododendron, the last two being even more desirous when in bloom. Dwarf conifers also, as the spreading Canadian yews (*Taxus*), junipers (*Juniperus*) and low pines (*Pinus*) form masses of grateful green in the foreground of shrubberies. Certain cornels (*Cornus*), which bear cymes of pretty flowers in summer, followed by white or blue fruit, are remarkable for their brightly colored twigs in winter; likewise willows (*Salix*), brightening toward spring, and Kerria, are useful for their tinted bark.

All those shrubs which bear winter berries are also important for color; they include sumach (*Rhus*); burning-bush (*Euonymus*) and its allies; barberries (*Berberis*); wild roses (*Rosa*); and deciduous hollies, especially that known as black alder; wax-myrtles and bayberries (*Myrica*), most of which also afford a winter fare for hard-weather birds. Others that are tempting to the avian palate, but which mature earlier are the spice-bush (*Benzoin*); choke-cherries (*Prunus*); red- and black-fruited elderberries (*Sambucus*); oleaster (*Eleagnus*); service-berries (*Amelanchier*); buckthorn (*Rhamnus*); sea-buckthorn (*Hippophæ*); buffalo berries (*Shepherdia*) and the white fruited snowberry (*Symphoricarpos*).

Among the flowering shrubs one can have blossoms in early spring on fragrant mezereon and Daphne (*Daphne*); on the sweet-scented Asiatic bush honey-suckles (*Lonicera*); on the drooping golden bell (*Forsythia*), and the scentless yellow jasmine (*Jasminum nudiflorum*). These are swiftly followed by pink and flaming azaleas; by the chocolate-colored, spicily-fragrant "Sweetshrub"; by Golden-flowered Kerria; by lilacs (*Syringa*) in all shades of purple and white; by flowering almonds (*Prunus*) and graceful snowy Deutzias; Kalmias and Rhododendrons come in June and July with a gorgeous company of Spiræas, some with hemispherical heads of white, some shooting up into spires of pink tiny blossoms. Huge snowballs (*Viburnum*) follow, the old-fashioned guelder-roses and the equally well-known Rose-of-Sharon (*Hibiscus*), tree-like covered with flowers like hollyhocks, pink or white. Single wild roses (*Rosa*) as the pink prairie-rose, the eglantine with lemon-scented foliage, and the robust Japanese roses are suitable for hedge-rows, in company with heavily scented mock-oranges (*Philadelphus*); pepper-bush (*Clethra*) and late white Azaleas; and with the scentless but floriferous raspberries (*Rubus*); garlanded pink Weigelas (*Diervilla*); the blue-spired Buddleia, delightful to butterflies; the smoke-like puffs of Rhus Cotinus and the heavy heads of Hydrangeas of ever-changing tints.

The seashore claims its own peculiar shrubby flora. Among those shrubs that may be planted along the dry strand are feathery Tamarix, each spray tipped with a wand of delicate rosy bloom; the native dark-colored aromatic bayberry (*Myrica*), dense clusters of high-water shrub, (*Iva*), fleshy-leaved like its neighbor, the Baccharis, which in autumn is smothered in white down of its fruits; and where the climate permits, wattles (*Acacia*) that are excellent sand-binders. Beach-plums wreathed with white bloom in early spring, hung with blue fruit in fall, and the creeping matted bearberry, thickly studded with scarlet berries, will thrive in sandy wastes.

Vines carefully trained over trellis or wall or tree are valuable for ornamental as well as for the more prosaic purpose of screens. Since their methods of ascension are different, these must be taken into consideration. Virginia creeper and its familiar relative, the Boston ivy (*Ampelopsis*) raise themselves by sucker-like discs at the end of tendrils, and are especially suited for creeping up walls, rocks and tree-trunks. European ivy (*Hedera*) and the American creepers (*Tecoma*) which ascend by thrusting out aerial rootlets, are equally adaptable for this use. Other common vines climb by tendrils or by weaving, twining or scrambling and are therefore useful for twisting about wires, or weaving into the meshes of a trellis. Wistarias are familiar examples of this sort, often becoming in age self-supporting, dropping their heavy purple and white racemes from tree-like trunk and branches. Bittersweet (*Solanum*), covered with purple star-flowers in summer and with yellow and scarlet berries in fall; honeysuckles (*Lonicera*) prodigal of scented yellow or pink or white blossoms or unscented red ones; Clematis, bearing either large formal flowers of white or purple, or small clusters of small white ones of the type known as traveler's joy, succeeded by gray fluffy seed-balls of feathery-tailed fruit; fragrant cinnamon vine (*Dioscorea*); matrimony vine (*Lycium*) throwing out long wands freighted with scarlet berries; Akebia quinata, delicate in foliage and gay in fruit; far-scrambling wild cucumber (*Echinocystis*); and humble gourds of all shapes with the hop (*Humulus*), laden with pale fruit, form verdurous screens.

Our wild bittersweet, or wax-work (*Celastrus scandens*) gorgeous with scarlet and gold far into winter; the delicate mountain-fringe (*Adlumia*) with its fern-like foliage and pink, saccate blossoms and the ground-nut (*Apios*) wreathed with violet-scented balls of old-rose tinted blossoms, are perhaps best left to garland fence and hedgerow. Climbing roses, such as the Baltimore Belle, the ubiquitous ramblers and various hardy hybrids are useful for trellis and garden arches, one of the best being the native prairie-rose (*Rosa setigera*) and its varieties. The South, however, can grow a number of climbing roses like the deliciously fragrant yellow Marechal Niel, the Gloire de Dijon and the wonderful single white Cherokee rose which takes possession of hedges. They have also the fragrant yellow jessamine (*Gelsemium sempervirens*) and the exotic star-flowered, perfumed white jasmines (*Jasminum*)

as well as the tropical Solanums with large blue flowers.

Climbing also in those favored lands are the incomparably blue Clitoris ternatea, purple and brick-red Bougainvillæas, smothered by their papery triple bracts; the gayly-colored climbing lily (*Gloriosa superba*), shell-pink rosa-de-montana (*Antigonon*) flinging its branched coral-like sprays in wild profusion; Clerodendrons with scarlet corollas peeping out of white bag-like calyxes; Thunbergias, some small, white or yellow with purple eye, some huge of leaf, fringed with long racemes of gigantic velvety flowers of white or purple. They have, too, quaintly-flowered Aristolochiæ, grotesquely shaped, strikingly reticulated with pale veins on a purplish or brownish velvety ground.

Convolvuluses are rampant in tropical climes, and great moonflowers, and the satiny chalices of pink and white and blue are common there, as well as the charming cypress-vines (*Ipomæa*) with delicately cut foliage, which are grown at the North as annuals.

If the size of the place prohibits the use of many trees or even of shrubs, there are still a number of perennial plants that are large and conspicuous enough to be truly decorative. Peonies form an important group of extremely hardy herbaceous plants, being found in many single and double varieties and as many hues, often rose-scented, moreover. Irises are a close second, having a bewildering number of species, types and colors, a constant succession of varieties being obtainable from early spring to midsummer. Lilies (*Lilium*), too, include many species of many colors, but always decorative and graceful, very often fragrant. Daylilies (*Hemerocallis; Funkia*) are also very decorative and form huge clumps, the orange and yellow varieties liking moisture and full sunshine, while the white and blue kinds prefer shade: this preference is shared by fragrant lilies-of-the valley (*Convallaria*) which carpet wide ground-space, and by evergreen, trailing periwinkles (*Vinca*) starred with purple blossoms in early spring. Some of the members of that large group, Campanula, both blue and white, also like shady places, and one species, the bluebells of Scotland is never so happy as when perched on rocky slopes or cliffs. It is one of the best plants for a simple rockery, sharing the damp stony location with dancing columbines (*Aquilegias*). Rosetted Saxifrages and Sedums, trailing Phloxes, sweetscented Daphne, and the scrambling rose (*Rosa wichuriana*) are all fit subjects for the sunnier aspects of a rockery, or for hot banks.

Aconites with cowl-like flowers of rich purple or yellow, Virginia bluebells (*Mertensia*); tall white Phloxes. and fragrant sweet rocket (*Hesperia*); scarlet and violet bee-balms (*Monarda*); and the stately foxgloves (*Digitalis*) are striking border plants for more or less shady places. In the full sun we may find the annual humble but glowing sunflower (*Helianthus*) splendid screening plants; azure larkspurs (*Delphinium*), ever a lure for humming birds; gray-green grass-pinks (*Dianthus*) profuse of fragrant bloom in June and evergreen throughout the winter, and the picturesque hollyhocks (*Althæa*). Hardy old fashioned pompon Chrysanthemums bloom gorgeously far into fall undisturbed by frosts, the stiff papery flowers of immortelles, the satin discs of honesty (*Lunaria*), and the vermilion, inflated calyxes of the Chinese lantern plant (*Physalis*), lend their cheer to the late garden, followed by the stiff waxy blossoms of the Christmas rose (*Helleborus*).

Southern climates permit of the culture of green-white Eucharis; Pancratiums and Crinums of varied hues; of viciously-armed Cacti and the stiff Aloes, Agaves and Yuccas, extremely decorative with their formal tufted growth and pyramidal bloom. There hothouse plants of the North, Heliotropes, Fuchsias, Begonias and Geraniums, become bushes, and the tea-rose blooms perpetually. They have also the gaudy dwarf Poinciana and the even more brilliant Poinsettias and Acalyphas (*Arundo*). Shrubby lantanas choke roadsides, and Bamboos and giant reeds form thickets.

Swampy lands and quiet pools, natural or artificial, filled with tepid water and with goldfish for the reduction of mosquitoes, can be turned into most decorative features, as bog- or aquatic-gardens. In the moist soil of the bog-gardens can be planted a variety of native plants such as the purple ironweed (*Vernonia*); the old-rose gigantic Joe-Pye-weed, and its smaller congener, the massive-headed, white boneset (*Eupatorium*); the vivid cardinal flower (*Lobelia*) and its blue relative: the pale turtle-head (*Chelone*) topheavy with its long continuing masses of oddly-inflated blossoms; yellow and magenta Lysimachias; goldenrods (*Solidago*); Asters and some of the more conspicuous orchids. The flaunting rose-mallow (*Hibiscus*), and marshmallow (*Althæa*) may also be suggested. The most splendid aquatic plants are in the genus Nelumbium, or lotus, our native species being pale yellow and the Oriental, pink or white, raised high in the air over huge umbrella-like leaves. Various waterlilies (*Nymphæa*) some hardy, and others tender, in the North, float on the surface of the pond, with the humble spatter-dock and the purple water-hyacinth (*Eichornia*) which is become such a pest in Southern water-ways, and gay water-poppies (*Limnocharis*).

Tall blue spikes of pickerel-weed (*Pontederia*) and the white fugitive flowers of the arrow-head (*Sagittaria*) and tufts of umbrella plant and ancient papyrus (*Cyperus*) rise above the water. HELEN INGERSOLL.

PLANTS, Physiology of. Since the plant is the ultimate source of all of the world's food, the study of the processes by which these substances which serve for food for man and beast are built up from the elements is exceedingly interesting and highly important. That is Plant Physiology. It is important because of its value in increasing food production. But apart from the utility of the study there is also an æsthetic value. There is keen pleasure in learning by observation and experiment how plants live and grow and reproduce their kind and incidentally supply food for the world.

As will be seen from a brief history of the development of the subject the scope has been extended gradually with increase of knowledge, and the particular aim in the study of the sub-

ject changes with different times and conditions. The aim of the first plant physiologist, Stephen Hales, is given in the preface to his book 'Vegetable Staticks' (1726): "Since we are assured that the all wise Creator has observed the most exact proportion of number, weight and measure in the make of all things; the most likely way therefore to get any insight into the nature of these parts of the creation which come within our observation must in all reason be to number, weigh and measure." Most of the early observers in plant physiology were interested in recent discoveries in animal physiology and were curious to see if plants behaved similarly. Hales compares the "quantities of moisture perspired" by plants and trees with the amount perspired by a man; the perspiration of a 160-pound man is to the perspiration (transpiration) of a sunflower plant as 141 to 100. Also after he had determined the force of blood in the arteries of dogs, he measured the pressure of the sap in grape vines. Again, Hales found that there is no circulation of sap in plants similar to the circulation of blood in animals, but that there is free movement of the sap upward and laterally. These few examples serve to show the general attitude of the first experimenters in plant physiology.

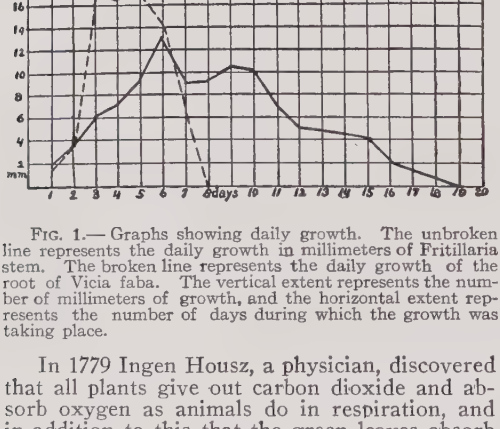

FIG. 1.— Graphs showing daily growth. The unbroken line represents the daily growth in millimeters of Fritillaria stem. The broken line represents the daily growth of the root of Vicia faba. The vertical extent represents the number of millimeters of growth, and the horizontal extent represents the number of days during which the growth was taking place.

In 1779 Ingen Housz, a physician, discovered that all plants give out carbon dioxide and absorb oxygen as animals do in respiration, and in addition to this that the green leaves absorb carbon dioxide and give off oxygen. This process is peculiar to plants and is the source of the carbon used in the manufacture of sugars, starches and other carbon compounds in the plant.

About 1800 Theodore de Saussure made quantitative analyses of the ash of many plants. By growing plants in watery solutions of the mineral substances found in the ash, he proved that some of these are necessary for growth. He also showed that nitrogen, one of the necessary elements, is obtained by plants from the soil and not in gaseous form from the air as had been thought. Boussingault in 1840 made an extensive series of experiments based on those of de Saussure and proved that the mineral substances necessary for plant growth are nitrogen, phosphorus, sulphur, potassium, magnesium, calcium and iron besides carbon which is obtained from the carbon dioxide of the air.

Although the foregoing important facts about the physiology of plants were discovered before 1850 they were not widely known. About that time Sachs, the first great teacher of plant physiology, collected all the isolated data, organized them and published them in his lectures on Plant Physiology. This was the real beginning of plant physiology as a science.

During the next 50 years plant physiologists were chiefly interested in quantitative measurements of the different life processes. New apparatus was developed to make these measurements more exact. One of these was the self-recording apparatus for measuring the rate of growth, first used by Sachs. The rate of growth per hour of roots and stems was determined for many plants. The rate of absorption of water by roots, the rate of flow of sap through trees and the amount of water loss per hour per square metre of leaf surface — all were determined for various plants. Sachs demonstrated the formation of starch in green leaves in the light and its disappearance in darkness, simply by putting the leaves in iodine solution. If starch is present they become blue, if not they stain yellow. Measurements were made of the amount of starch formed per hour per square metre of leaf surface.

An important piece of work of this period is that of Pfeffer (1877). In an attempt to find what physical forces are available to do work in the plant, he measured the pressure which sugar solutions exert when separated from water by a membrane. This is the condition in root hairs: the cell sap (sugar solution) is separated from the water of the soil by a membrane. Pfeffer found that the pressure is proportional to the concentration of the solution. The pressure in plant cells varies from four to 50 atmospheres.

A phase of physiology which received much attention during this period is that of plant movements. From early times people had been interested in these movements. The turning of stems toward the light, the drooping of the leaves of the sensitive plant on contact, the movements of tendrils and twining plants — all these attracted the attention of the observer. There were attempted explanations of the mechanical force involved in the curvatures. Ray in 1693 thought that all curvatures were due to differences in temperature on the two sides,— that the warmer side grows more rapidly, and, therefore, becomes convex. In 1806 Knight by ingenious experiments proved that the upward growth of stems and the downward growth of roots is due to the influence of gravity. He grew germinating seeds on a centrifuge, which was revolved rapidly, thus substituting centrifugal force for the force of gravity. The roots grew in the direction of the centrifugal force, the stems in the opposite direction. Now followed a period when "vital force" was offered as an explanation of plant movements, or indeed of any plant behavior which was not understood. Sachs scorned the vital force conception and initiated experiments to discover the physical or mechanical basis for plant movements. Unfortunately before any real progress had been made, the "stimulus" conception was offered as sufficient explanation. Light acts as a stimulus, therefore stems turn toward it. Gravity acts as a stimulus, therefore roots grow downward. A vast number of use-

less experiments on movement were made during this period. Since 1900 plant physiologists are seeking to find, not necessarily the *cause* of movements, but those chemical and physical changes within the organ which precede and accompany the movements. An important discovery is that of Lepeschkin (1910). He found that the cells in the upper side of the swelling at the base of bean leaves are more sensitive to light and darkness than those in the lower side. In the light the cell membranes in the upper half become more permeable, therefore the cells lose some of their sugar, and become flaccid; the upper side becomes concave and the leaf rises. In darkness the opposite process takes place: cell membranes become less permeable, therefore the cells retain their sugar and absorb more water; this causes the cells to swell; the upper side becomes convex and the leaf droops.

From 1900 up to the present there has been a rapid increase in knowledge of the chemistry of plant life,— of the chemical constitution of the sugars, proteins and many other substances which are found in plants; also, and this is much more important, an increasing knowledge of the chemical and physical processes which are going on in the living plant. In his work the plant physiologist now makes use of all the methods and apparatus available from the sciences of physics, organic and physiological chemistry. The close relation between the science of plant physiology and the arts of agriculture and horticulture is now being recognized, and the facts discovered by the plant physiologist are made use of in agricultural and horticultural practice.

The progress in the attitude of plant physiologists with increasing knowledge may be illustrated by the questions which they have sought to answer concerning a single plant organ — the green leaf. Before 1850: What is the function of the leaf? What the function of the green color?

From 1850 to 1900: What is the amount of work done by the leaf? The amount of starch formed per hour? The amount of water lost per square metre of surface? The amount of carbon dioxide absorbed and oxygen given off in the light? The amount of oxygen absorbed and carbon dioxide given off during respiration?

From 1900 to 1918: What are the physical and chemical processes by which sugar is made in green leaves? What conditions of soil and what proportion of mineral substances are necessary for the production of the greatest amount of sugar in leaves? What is the ratio between the sugars and mineral substances, especially phosphorus, in the plant which cause fruitfulness?

PLANTS, Poisonous, those inflicting toxic disease upon men or animals. The most widely dreaded toxic plants in America are doubtless those poisonous to the touch. Such are those commonly called poison ivy, poison oak and poison sumac (also known as swamp sumac, or poison elder). All of these affect certain constitutions disastrously even after drying, as in hay, for they contain a glucoside (long believed to be an oil) which, upon touching the skin, starts severe inflammation, with intolerable itching and a vesicular eruption which destroys the outer skin. These symptoms may not appear for four days. Immediate washing the skin after touching with gasoline is effective. Bathing with a very hot suds made with laundry soap quickly relieves the itching, and may be repeated if needful.

All the above-named plants belong to the genus *Rhus* and are often confused with innocuous plants, the Virginia creeper being at times destroyed as poison ivy. The common poison ivy (*Rhus toxico dendron*) is a climbing trailer, with varying 3-foliate leaves, aerial rootlets and greenish flowers. The smooth, greenish berries often remain on it until late in the winter, forming a food for birds, which disseminate the plant. The leaves differ from those of the Virginia creeper in having only three leaflets instead of five, and they are of a peculiar dark green, and glossy as though waxed. The poison ivy grows everywhere, in open brush, in ravines and on the borders of woods; it climbs tall trees, and luxuriates in fence corners, often rearing its head high above the posts. In autumn it assumes brilliant colors, and is oftentimes picked for ornament,— with unfortunate results.

The poison sumac grows in swamps from Florida to Canada and westward to Louisiana. It is a tree-like shrub, 6 to 30 feet high, with long pinnate leaves having from 7 to 13 smooth and glossy leaflets, on red petioles, and without marginal teeth. The wood has a faint sulphurous odor, which, together with the leaf scars, which are very prominent, enables one to distinguish the plant from other shrubbery in the winter. The loose, grape-like bunches of silver-gray berries are also visible in the winter and are a frequent source of poisoning, being picked for ornament. This is the *Rhus vernix.*

The western poison oak has the same unpleasant toxic characteristics, and differs from the poison ivy mainly in the character of its leaflets, which are smaller and thicker and have rounded lobes. This is *Rhus diversiloba.*

Other plants, less common, but quite as virulent to some people, are the handsome ladies' slippers, the largest, the crimson and white *Cypripedium hirsutum,* growing in sphagnum swamps, producing almost identically the same symptoms as the sumacs. The juice of several spurges (*Euphorbia*) excites similar inflammations.

Plants having poisonous fruits are perhaps the most dangerous, especially to investigating children. There are several kinds of berries, like those of the pokeweed, bitter sweet and night shade, and the black cherry kernels, which are poisonous, when eaten rashly, but the most destructive fruit is probably that of the thorn-apple, or Jimson weed (*Datura*)— a fruit most unappetizing in appearance, covered with spines, and holding hard black seeds, containing several poisonous alkaloids. The plants are rank and ill-smelling smooth and bushy annuals. with

arge irregularly flaccid leaves, and large flowers, white or purple according to species, blooming at night, and resembling half-opened, long-tubed morning-glories. They are found on waste lands and rubbish heaps.

The water-hemlock (*Cicuta maculata*) is also responsible for many deaths. It belongs to the great carrot family, which contains both edible and poisonous roots and seeds. It is a smooth erect perennial, three to eight feet high, with a rigid, hollow stem, marked with purple lines, numerous branches, finely dissected leaves, tiny white flowers, disposed in the familiar flat umbels of the wild carrot or sweet cicely, and a cluster of spindle-shaped roots, which vary in length from one and one-half to three inches, and are very characteristic. This is one of the most poisonous native plants in the United States, being rapidly fatal to both man and animals. The roots are especially dangerous, because the taste, being aromatic and to some people suggesting that of horseradish, parsnips, artichokes or sweet cicely, is apt to lead children to eat them when they are found forced out of the soil by washing, freezing or other causes in early spring. Cattle sometimes eat the tubers, and in marshes they are poisoned by drinking water contaminated by the juice of roots which have been crushed by being trampled upon. No estimate can be made of the amount of damage done to livestock, but it is very considerable. The human victims average several per annum.

The historic poison hemlock of Greek fame is another violently poisonous plant, in all its parts. Similar in appearance to the other hemlock, with purple spotted stems, and a mouse-like odor when bruised, it is becoming naturalized in waste places, and is dangerous when seeds, foliage or roots are eaten.

The beautiful evergreen mountain laurels (*Kalmia*) conceal a strong poison in their leaves, as do other closely related species of the Heath family, such as the *Rhododendron*. The smaller laurel, *K. angustifolia*, carries the suggestive name of lambkill. Livestock are the principal sufferers from these plants, scores being poisoned and killed by them annually, but children are sometimes poisoned by eating young shoots, which grow with and closely resemble wintergreen, but are without the spicy flavor of the latter. Honey is said to be rendered poisonous when bees feed upon the *Kalmia* pollen.

Livestock are also often killed by eating the poisonous fruits of the buckeye (which with the young shoots were bruised and thrown into ponds, stupefying fish and rendering their capture easy); they are also poisoned by the leaves of the black cherry, especially when wilted.

In the West the sneezeweed (*Helenium*), the larkspurs, rattlebox and the loco- or crazy-weeds are the dread of stock-raisers. The latter (*Astragalus*), silvery-white, silky-leaved perennials, have a most peculiar effect on horses. It is not an acute disease and has two recognized stages. The first, which may last several months, is a period of hallucination or mania accompanied by defective eyesight, during which the animal may perform all sorts of antics. After acquiring a taste for the plant it refuses every other kind of food, and the second stage is ushered in. This is a lingering period of emaciation, characterized by sunken eye-balls, lustreless hair and feeble movements. The animal often dies, finally, as if from starvation.

Human beings occasionally poison themselves by cooking various plants in mistake for the harmless "greens" or salad plants. Toadstools, perhaps, cause as many poisoning cases as any other plants. The attractive-looking Amanitas are continually being gathered by careless or ignorant people in mistake for the true edible mushrooms, and very often cause death.

PLANTS, Recapitulation in. The term, recapitulation, in plants and also in animals, is used to designate features of the embryogeny and early development of the individual. "Ontogeny recapitulates phylogeny" is the usual classroom term, meaning that the individual, in its own development, repeats the history of the race. The frog is first a pollywog and then tadpole, before it finally reaches the adult stage. This is interpreted to mean — according to the recapitulation theory — that the frog's very remote ancestors were adult at the pollywog stage; and that its less remote ancestors were adult at the tadpole stage. The frog, in its individual life history, repeats these phases of its ancestry. Zoological literature is full of illustrations. In plants, illustrations of recapitulation are just as numerous, but are not so widely known. In many trees and shrubs, the early leaves of the seedling are quite different from the leaves of the adult plant. The Ginkgo, or Maiden Hair Tree, offers a good example. The leaves of the adult tree have an even, wedge-shaped outline (Fig. 1, *D*) or have a notch at the apex (Fig. 1, *C*), the latter condition suggesting the specific name, *biloba*, the scientific name being *Ginkgo biloba*. The

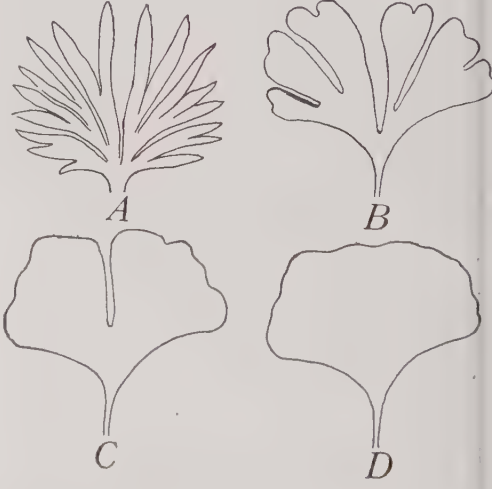

FIG. 1.

leaves of the seedling, and also the leaves at the tops of young trees, do not have such a simple outline, but are deeply cleft (Fig. 1, *B*). This is significant, for the geological ancestors of Ginkgo — like the *Baiera* — have just such cleft leaves at the adult stage (Fig. 1, *A*). In the common larch (*Larix*) the seedling has simple, needle leaves, and such leaves are found on the first year's growth from any bud on the

tree; but later, the leaves appear in dense clusters on short spurs. In the pine, the seedling has short needle leaves, but later the leaves are longer and occur in twos, threes or fives on short spurs. Examples might be multiplied. The early form of leaf is called a "juvenile" leaf, and many believe the seedling is passing through a stage which characterized its adult ancestors. All Pteridophytes (ferns and fern allies), which have two kinds of spores, furnish excellent illustrations of recapitulation. *Selaginella,* a very common greenhouse plant, may be taken as an example. In its early development, the megasporangium is just like the sporangium of a common fern which is to produce only one kind of spore. In *Selaginella* itself, the microsporangium looks very like the sporangium of a common fern. All of its spores reach maturity. In the megasporangium, the spore tissue develops just as in a fern and mother cells round off, as if to produce the usual four spores; but only one mother cell undergoes the expected division, giving rise to four spores, while all the rest of the mother cells disorganize and their substance is absorbed by the four spores. *Selaginella* repeats an ancestry in which the spores were all alike and all functioned. The protonema of a moss

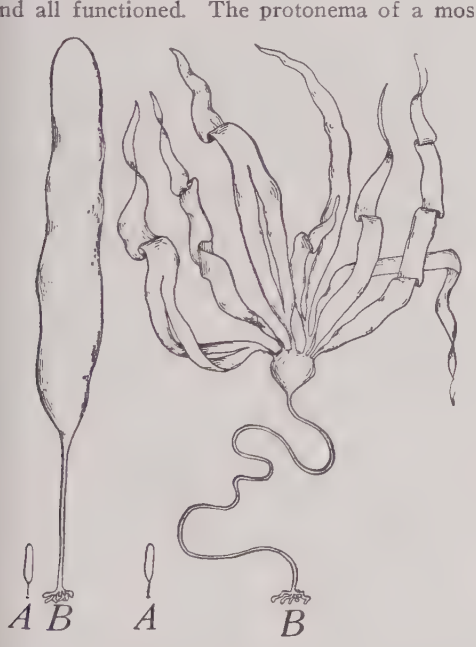

FIG. 2. FIG. 3.

FIG. 2.—*Laminaria.* A, sporeling, B, adult form.
FIG. 3.—*Nereocystis.* A, sporeling, B, older but not yet adult form.

repeats an algal ancestry. In the Algæ, illustrations are numerous. The common kelp, *Laminaria,* in its early development, has a small, flat blade, and in the adult plant the blade has simply grown larger. In *Nereocystis,* one of the Giant Kelps of the Pacific Ocean, the young plant has the simple blade, but the adult form is much more complex. Compare Fig. 2 *A* and *B* with Fig. 3 *A* and *B*.

The Fucaceæ, the family to which *Fucus,* the most familiar of all brown seaweeds belongs, offer a fine illustration in the microscopic details of recapitulation. In the oogonium of *Focus* eight nuclei are formed and each nucleus becomes the centre of an egg. In most of the other genera of the family, the eight nuclei are formed, but some of them disorganize, so that the mature oogonium contains only four or two eggs, or even only one. *Fucus* shows the ancestral condition. The others pass through the Fucus stage on account of this phase of heredity known as recapitulation. In studying the relationships of great groups, orders, families, genera and even species, recapitulation furnishes valuable suggestions. Consult Wilson, E. B., 'The Cell in Development and Inheritance'; Spencer, Herbert, 'The First Principles of Evolution.'

PLANTS, Regeneration in. The subject of regeneration has received much more attention from zoologists than from botanists. It has long been known that if the leg or tail of a salamander be cut off, a new leg or tail will be formed, or "regenerated." If an earthworm be cut into three pieces, the anterior piece will develop a tail; the posterior, a head; and the middle will develop both a head and a tail. These illustrations indicate the general application of the term, regeneration, in animals.

In plants, the term has been applied rather loosely, but in some cases a missing part may be replaced, or regenerated and the term, regeneration, might well be limited to the replacement of an organ or structure which has been removed, as in the case of the replacement of a leg in the salamander. In some plants, if the apex of a root be cut off, the missing part will be restored (Fig. 1, *A* and *B*), but if the cut

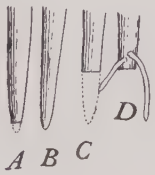

FIG. 1.—Regeneration in roots; a small portion cut off (A) is restored (B); a larger portion, cut off (C) is not restored, but new roots form above the injury (D).

be too far back from the apex a new root tip is not restored, but new roots develop a short distance behind the cut surface (Fig. 1 *C* and *D*). If the shoot of a common dandelion be cut off some distance below the leaves new shoots develop from the cut surface of the root. Many plants with strong, fleshy roots behave in this way. If a vigorous willow twig be cut off and the cut end be placed in soil or in water, roots will develop from the lower part, just above the cut surface (Fig. 2). If the part in the water has buds, roots may develop at the lower part of the bud.

From stumps of trees it is very common to find new shoots developing and they may even develop into trees. It used to be assumed that such shoots come from dormant buds, but it is now known that in most cases there are no such buds in the region from which the shoots originated. They come from the cambium or from embryonic tissue induced by the wound. In "pollarded" willows many of the shoots arise in

this way, although some come from buds already present. In the cycads, buds develop from almost any wounded portion of the trunk, the bud arising from the cambium or from embryonic tissue due to the wound. In this case, dormant or latent buds are entirely out of the question, because the cycad stem has only one bud and that one is terminal. The underground stem of the cycad, *Zamia,* may be cut into several pieces and shoots will develop from the

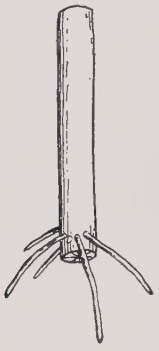

FIG. 2.— Behavior of Willow twig when cut off and placed in water.

cut surfaces. This case is different from that of the potato, for the potato, as it is cut for planting, has several eyes or buds in each piece from which the new plants are formed.

Many plants are propagated from cuttings. In the *Begonia* or *Bryophyllum,* the leaf is cut into several pieces and a whole new plant is developed. This behavior differs from that noted in the salamander where a new leg grows and replaces one which has been cut off, for the piece of a leaf does not replace the missing parts and become a whole leaf, but produces a bud and a root which develop into a complete plant.

While a great deal of observation and a considerable amount of investigation has been done along the lines indicated, the term regeneration is so elastic that botanists still use it in describing the various cases to which we have referred.

PLANTS, Sex in, Origin, Evolution and Determination of. For the origin of sex and the early stages in its evolution, one must turn to the algæ and fungi, since all plants from the liverworts to the sunflowers and orchids have already reached that degree of development which is characterized by eggs and sperms. In lower members of the algæ, reproduction by swimming spores is common. Repeated divisions within a cell give rise to several nuclei, each surrounded by a mass of protoplasm. (See CELL; CHROMOSOME and PROTOPLASM). Each mass of protoplasm, with its nucleus, becomes transformed into a swimming spore, which owes its motility to thread-like cilia. The spore comes to rest, elongates and then divides transversely. By repeated divisions, a filament like the parent plant is built up (Fig. 1, *A*). In *Ulothrix,* which is commonly used for illustrating the origin of sex, the zoospores are formed, 1, 2, 4, 8 or 16 in a cell. If one, two or three more divisions take place — the cells divide simultaneously — so that 32, 64 or 128 cells are produced, the cells develop into the motile condition but seem too small and deficient in energy to divide. However, they unite in pairs — for which reason they are called gametes — their protoplasm fuses into one mass and the two nuclei blend into one. The result of the union is a vigorous cell which may at once develop into a filament like that produced by the zoospore, or may produce a few zoospores, which then behave like those formed in the cells of a filament (Fig. 1, *B*). Thus the gamete habit originated from the zoospore habit, and sexuality, characterized by the fusion of two gametes, represents an advance beyond the zoospore condition. The zoospore is the ancestor of the gamete. The gamete habit arose from the zoospore habit independently in various algæ and fungi. In the illustration just given, the two gametes are of the same size and shape; but, after the gamete habit became established, the gametes began to differ, one remaining small and active, and the other growing larger and less active and finally losing the swimming habit. When the two gametes have begun to differ in size, the terms, male and female, may be used, the smaller being the male and the larger the female; also, the male gamete may properly be called a sperm and the female an egg. Stages in the evolution from similar gametes to highly differentiated eggs

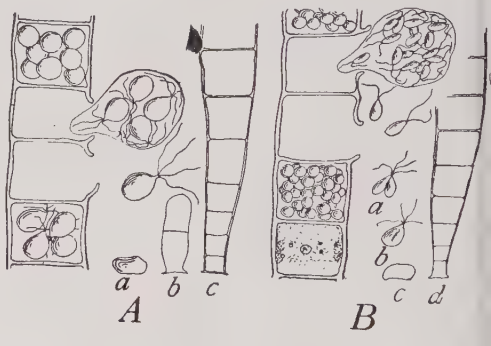

FIG. 1.— *Ulothrix,* one of the green algæ. *A,* portion of a filament, at the left, showing cells producing zoospores: *a,* the zoospore has lost its cilia; *b,* zoospore has elongated and divided; *c,* further divisions have resulted in the formation of a filament. *B,* cells producing gametes: *a,* two gametes uniting; *b,* the cell formed by the union; *c,* cilia have been resorbed; *d,* a filament has been developed. Greatly magnified.

and sperms may be illustrated by *Cutleria,* one of the brown algæ, in which the egg, although motile, is much larger than the sperm. In *Oedogonium,* a very common green alga, the egg is immensely larger than the sperm and has not only lost all motility, but remains in the cell (Fig. 2, *A* and *B*). From this stage in the evolution of sex, the egg is always retained in the organ which produced it, further development being more conspicuous in the organs

which produce and nourish the eggs and sperms than in the eggs and sperms themselves. In liverworts, mosses, ferns and their allies, and in most Gymnosperms, the organ which produces the egg is called an *archegonium* and that which produces sperms is called an *antheridium*, although in the Gymnosperms the antheridium character is not so obvious to the layman.

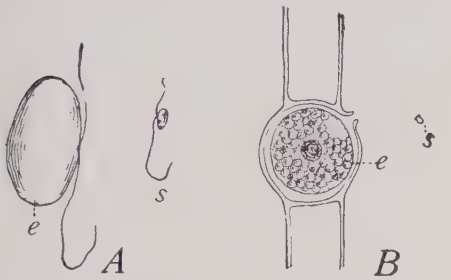

FIG. 2.—*A, Cutleria: e,* egg; *s,* sperm. *B, Oedogonium: e,* egg; *s,* sperm.

In the Gymnosperms the eggs arise in structures concealed in large cones and the sperms are finally developed from spores which were produced in smaller cones. We have no hesitation in calling these larger cones female cones and the smaller ones male. In the same way we should call the ovaries of the Angiosperms female organs and the anthers, male. When ovaries and anthers are formed on separate plants, as in the willows and many others, we believe it is perfectly correct to speak of male and female trees. Some botanists object to using the terms male and female, except as applied to the gametophyte generation. (See ALTERNATION OF GENERATIONS). The determination of sex is a problem which is receiving increasing attention from zoologists, especially it has been determined that, in at least some cases, the sexes are characterized by differences in the number or sizes of chromosomes, e.g., in one of the worms, two of the four sperms produced from a mother cell has five chromo-

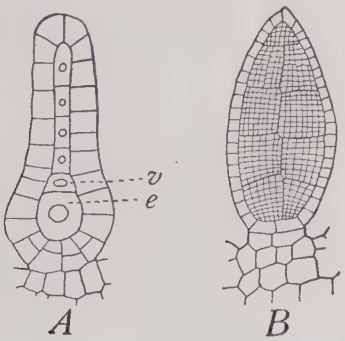

FIG. 3.—*Archegonium, A,* and *antheridium, B,* of a liverwort; *e,* egg; *v,* ventral canal cell.

somes while the other two have six. All of the eggs have six chromosomes. An egg fertilized by a sperm with five chromosomes produces a male individual, while fertilization by a sperm with six chromosomes results in a female individual. In plants, investigations have not advanced to any such extent but it is known that, in some cases, the two sexes are differentiated during the reduction of chromosomes (see CHROMOSOME), while in others the differentiation takes place at various stages in the life history. In both animals and plants, efforts have been made to control, artificially, the sex of offspring, chiefly by nutrition. If the number or size of the chromosomes should be the determining factor, no experiments in nutrition could affect the result, unless such experiments could affect the chromosomes. Professor Emeritus of Morphology and Cytology, University of Chicago.

PLANTS, Structure of. The cell, the elementary organ of plants and animals, was first observed by the English micrographer, Robert Hooke (1667), who suggested the name "cell" because of its resemblance to the cell of a honeycomb. A few years later another English author, Nehemiah Grew, extended this observation and published the first work on plant-anatomy (1672), in which he described the minor structure of leaves, stems and roots, and introduced several anatomical terms still in use. Grew was soon followed by an Italian, Marcello Malpighi, the author of the illustrious work, 'Anatome Plantarum' (1675), and these three men are thus the founders of the science of plant morphology, as the study of plant structures is now called, the term anatomy being restricted to the study of plant tissues. Many years later Robert Brown (1833) detected the nucleus in the cell, and the German botanist Schleiden (1838) pointed out the general occurrence of this new body within the cells of plants and its importance to the cell-division. These discoveries soon led to the apprehension of the cell as being the elementary organ of plants, and when the occurrence of nucleus had been proved also in the cells of animals the German naturalist Schwann (1839) advanced the important doctrine that bodies of animals and plants consist of cells and the products of these.

While the nucleus had thus been detected and described to some extent, there still remained a closer examination to be made of the other parts of the cell-contact, which some of the earlier investigators had already observed and described as a soft, gritty matter, capable of motion in the cell. This cell-content was studied by Mohl (1846), who gave it the name protoplasm. The constituents of the cell were thus properly defined as the cell-wall, the protoplasm and the nucleus. Of these the protoplasm and the nucleus are the most essential parts, since the wall is not always developed, but is totally absent in numerous animal-cells and also in those of several plants among the lower *Algæ* and *Fungi*, at certain stages, for example. A completely developed plant-cell may for the most part be defined as a microscopical, closed vesicle consisting of a wall, and the contents, nucleus, protoplasm and cell-sap. The shape of the cell presents a vast number of forms, generally referred to only two types: the parenchymatic and the prosenchymatic. Of these the parenchymatic is either isodiametric or elongated, but with blunt ends and usually thin-walled, while the prosenchymatic is mostly

elongated with pointed or sharp endings, and is more or less thick-walled. A third type of cell may be mentioned, the "hypha" of certain *Algæ* and *Fungi*, which is very thin, thread-like and composed of a single cell or many. There are plants consisting of one cell only, but most plants are composed of an enormous number, which together constitute the so-called "cellular tissues," parenchyma and prosenchyma, in respect to the shape of the cells of which they are composed. The function performed by these tissues is very different, and the classification as parenchyma and prosenchyma is thus not sufficient, since this only applies to the external shape of the cells. In accordance with both structure and function the following tissues are observable in the higher plants: Epidermis, the mechanical tissue, the conductive tissue and the fundamental tissue; the first and the last of these tissues being parenchymatic, the others prosenchymatic.

The minor structure of these various tissues may be described as follows:

Epidermis.— This is the outermost cell-covering of a plant-organ, such as the leaf, stem and root, and consists of at least one layer of cells. The outer cell-wall is often considerably thickened and invariably covered by a thin membrane, the so-called cuticle (*c* in Fig. 1) which is highly impermeable to water, and

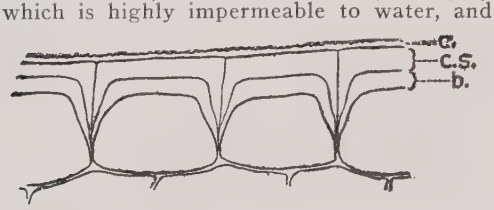

FIG. 1.— Epidermal cells of the leaf of aloe: *c*, the cuticle; *c. s.*, cuticular layers; *b*, cellulose.

especially well developed in land-plants; in submerged water-plants the cuticle is, on the other hand, much reduced. The epidermal system of plants has a threefold significance: it protects the more delicate parts of the organs against mechanical injuries, pressure, etc.; it forms a protection against evaporation by being impermeable to water and water-vapor, and forms also a water-supplying system. These three functions are expressed by various development of the cells, which may be illustrated by a section of a leaf of aloe (Fig. 1) in which all three epidermal peculiarities are quite well developed. The thick cuticle and cuticular layers form an excellent protection against loss of moisture, while the thickening of the outer cell-wall and portion of the radial walls furnishes the mechanical support. Characteristic of epidermis, furthermore, is its covering of hairs, which present a number of forms and of which the majority are developed from the epidermis itself. Some of them consist only of a single cell, but usually they are composed of several. The hairs may be simple or branched and attain various forms from sharply pointed to globose, scale-like or star-shaped. The ordinary hairs contain only air, and when occurring as a dense covering of the plant-organ aid materially in the protection against loss of moisture, thus entering directly into the function of epidermis. Other hairs contain and secrete ethereal oils, the so-called glandular hairs, which may serve for attracting insects to carry the pollen, or if the secretion is of a sticky consistence, the function may be to keep off injurious, crawling insects, less adapted for aiding in cross-fecundation. Several hairs contain poisonous matters and cause great pain when touched, as, for instance, the hairs of the common nettle, but the physiological significance of such and other hair structures is not satisfactorily explained.

A very simple structure is possessed by the root-hairs, which consist of only a single epidermis-cell, and of which the function is to absorb and conduct food substances in solution. A purely mechanical function is exhibited by the climbing-hairs — that is, hairs in the shape of hooks by which the weak stems of certain plants — for instance, hop, cleavers, etc.— are able to climb by attaching themselves to other plants.

Finally to be mentioned are the stomata. If the epidermis be able to regulate the evaporation, it is readily understood that this tissue must be compact and without intercellular spaces unless these be capable of closing and opening themselves under certain conditions. Such intercellular spaces occur in the epidermis and were by De Candolle named "stomata." Each stoma consists of two crescent-shaped cells, the guard-cells, which turn their concave faces against each other, thus forming an intercellular space leading into a wide cavity, the so-called air-chamber (as in Fig. 2). Adjoin-

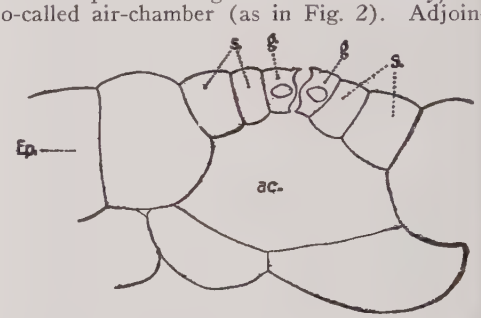

FIG. 2.— Cross-section of a stoma from the leaf of *Commelina*; *ac*, the air-chamber; *g*, guard-cells; *s*, subsidiary cells.

ing the guard-cells are usually two or more epidermis-cells of a shape somewhat different from the others, and these have been called the subsidiary cells; their number and manner of arrangement is often very variable in several orders of the phanerogams. The guard-cells are, as a rule, the only cells of epidermis which contain chlorophyll and starch; they have the power of closing or opening the orifice of the intercellular space, a phenomenon that has been studied and explained by Schwendener. When moist these cells become swollen, and, as they lengthen, curve outward in the middle so as to leave a free opening. An opposite movement takes place when they become dry: they are then shortened and straightened with their inner faces applied to each other, closing the orifice. Stomata occur as a rule on all green plant-organs, stems and leaves, but lack in those that are constantly under water, and they are totally absent in the thallophytes. The location of the stomata varies somewhat, but they are more numerous on the lower face of the leaves than on the upper. Their position offers a number of variations and is sometimes dependent upon the nature of the surroundings, especially of the climate, the dryness of the air,

etc. The guard-cells may be free, reaching above the surrounding epidermis, or they may be sunk below this. A very peculiar arrangement is noticeable in *Nerium*, where the stomata are located, several together, in depressions of the leaf-surface. A modification of stomata are the so-called water-pores, exhibiting a like structure, but somewhat larger than these and unable to open or close themselves. They are mostly located on the margins of leaves near the ends of the nerves.

The Cork.— While the epidermis is seldom of any long duration in plant-organs which persist for more than one season, another covering becomes necessary and is represented by the so-called cork. This tissue may be developed by the epidermis itself, but in most instances it originates in the parenchymatic layers underneath the epidermis, or sometimes much deeper, in the innermost portion of the cortex, for instance. The cork is able to continue its growth, following the increase in thickness of the stem, and consists of several strata of quadratic or rectangular cells, arranged in compact rows, vertical on the surface of the plant-organ.

The Mechanical Tissue.— The best-known elements of this tissue are the so-called "sterome-cells," which are thick-walled, very long prosenchymatic cells, of which the walls have narrow pores and consist of cellulose. The sterome-cells are mostly arranged in strands and located in such portions of leaves or stems as are the most exposed to injury. The cells are very flexible, and the arrangement of the layers is remarkably well fitted for rendering the plant-organ the greatest possible support by means of the smallest quantity of material, as demonstrated by Schwendener. Besides this function the mechanical tissue is also observed to form protective layers around the mestome-bundles, especially near the leptome-elements.

Another thick-walled but parenchymatic cell-form is the so-called sclerotic, occurring in the cocoanut, walnut, etc.

The Conductive Tissue.— This tissue is represented by the so-called "mestome-bundles" or "vascular bundles" of earlier authors, which traverse the plant-organs mostly in a longitudinal direction; they constitute a part of the nerves in leaves and of the wood in trees. Their composition is often very complicated, especially in stems and roots, where they are often associated with some of the other tissues, from which they are not always readily distinguished. At present "mestome," as proposed by Schwendener, comprises only two elements, "leptome" and "hadrome," of which the former conducts albuminous matters and contains the sieve-tubes and the medullary ray-parenchyma. The hadrome contains the vessels and the woody parenchyma and conducts the water. These terms, leptome and hadrome, are not identical with the "phooëm" and "xylem" formerly suggested by Nageli, since this author included the mechanical tissue, the stereome, which is often developed in almost immediate connection with the true conductive tissue.

Mestome-bundles, containing leptome and hadrome, are observable in all the higher plants: vascular cryptogams and phanerogams, but are not developed in any of the thallophytes (*Fungi* and *Algæ*) or in the mosses.

The Fundamental Tissue.— This tissue comprises all the other tissues of the plant not referable to the epidermis, the mechanical or the conductive tissue, and is as a rule composed of thin-walled, parenchymatic cells with distinct intercellular spaces. Its function is principally to prepare and store nutritive matters, hence the chlorophyll, the starch and similar matters are contained in this tissue. Several types of fundamental tissue have been distinguished in the various plant-organs, such as the cortex in stems and roots; the pith in stems, but only occasionally in roots; the mesophyll with the palisade- and pneumatic-tissue in leaves; and finally the parenchymatic sheaths, which often surround the mestome-bundles as the endodermis, the mestome-sheath, etc.

The Root Structure.— The fact that the root is only slightly susceptible of modification in respect to its external structure is especially expressed by the great uniformity that prevails in its internal structure. Roots, however, are not always quite as uniformly developed as generally described, but very few botanists have paid much attention to their structural peculiarities. Some types of roots have been suggested — for instance, "nutritive," "attachment," "contractile" and "storage" — all of which possess a somewhat modified structure corresponding to their functions. But common to all roots are the following tissues: Epidermis, cortex, pericambium and the conductive tissue.

The Structure of the Stem.— The minor structure of the stem of the above- and underground differs materially from that described as characteristic of normal roots, even if the tissues themselves are much the same. There is an epidermis, a cortex, a mechanical- and conductive-tissue besides a pith, but no pericambium. The stem, however, exhibits a much larger plasticity than the root, and the numerous modifications that occur in respect to the mere external structure are usually accompanied by a corresponding variation in its interior. Marked distinctions are noticeable in stems when we compare the herbaceous with the woody, the annual with the perennial, the terrestrial with the aquatic, and the aerial with the subterranean,— distinctions that have been very extensively studied and have rendered it possible to identify fragments of such stems merely by the aid of the microscope.

When compared with the root, the presence of a pith is characteristic of the stem, while on the other hand a pericambium is observable only in roots. The minor structure of the stem is thus very variable.

The Structure of the Leaf.— The manifold variation exhibited by leaves corresponds also with certain modifications of the internal structure, but to a much less extent than observable in stems. The various functions performed by the leaves do not require such great internal modification as is necessary to the stem, even if the leaves exhibit a metamorphosis of no small importance. The stem-leaves and the floral leaves naturally show conspicuous anatomical distinctions, and the fleshy leaves of bulbs are of course very different in structure from the thin, scale-like leaves of tubers and stolons. However, the principal structure, such as is ex-

hibited by the relative development and arrangement of the main tissues, for instance the mesophyll (the chlorohyll-bearing parenchyma including the palisade- and the penumatic-tissue), the stereome and the conductive tissue, is not very variable in leaves when we consider the enormous variation in the shape and size of their outline. In the leaves the epidermis is perhaps the tissue that is subject to the most conspicuous modification, which is especially noticeable in the development of the cells when examined on both surfaces of the leaf, above and between the nerves. The various arrangements of the stomata often cause a modification of the surrounding strata, which is less pronounced in the stems. Thus the epidermis, when examined superficially, exhibits several distinct forms of cells, rectangular, polyhedric, or with the outline very prominently modulate. The covering with hairs is especially characteristic of leaves, and several types of these may be found to occur on the same leaf. The cuticle is usually very distinct, and renders by its various consistence the most essential protection to the leaf while performing its functions. Besides the epidermis, corky layers may be developed, at least locally, in leaves which per-

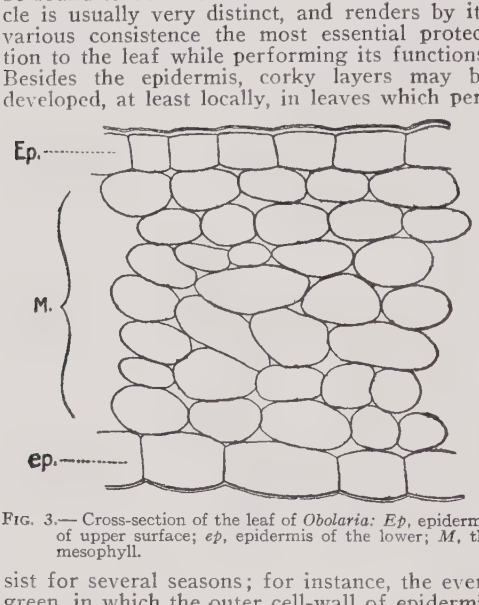

FIG. 3.— Cross-section of the leaf of *Obolaria: Ep*, epidermis of upper surface; *ep*, epidermis of the lower; *M*, the mesophyll.

sist for several seasons; for instance, the evergreen, in which the outer cell-wall of epidermis often becomes very considerably thickened.

The mesophyll is generally differentiated as a palisade- and a pneumatic-tissue, the former located on the upper face of the leaf, just beneath the epidermis, while the latter occupies the lower portion. In some leaves the mesophyll is not differentiated into these two tissues, but only as a homogeneous (Fig. 3) tissue; such leaves are called "isolateral" in contradistinction to the others, the "bifacial." Otherwise the mesophyll possesses the same forms of reservoirs, ducts and lacumes as are characteristic of the cortex.

The leaf-structure thus possesses less variation than that of the stem, if we compare the relative development and the arrangement of the tissues, especially of the mesophyll, the stereome and the mestome. The main variation seems to lie in the epidermis, and becomes especially noticeable in the comparison of leaves of plants that grow under diverse conditions — of terrestrial and aquatic plants, for instance. Among the former the desert-plants are known to possess highly complicated structures, which naturally are expressed by th epidermis and the mesophyll rather than by th other elements. But considered as a whole, th leaves show less modification of the inner tis sues than the stem, and when some prominen variations are found to occur in leaves thes are generally observable also in the stems of th same plants. See under PLANTS, STRUCTURE OF BOTANY.

PLAQUEMINE, plăk-mēn', La., town an Iberville Parish seat; alt. 28 feet; on the Missis sippi River; on the Texas and Pacific Railroad 15m. S. of Baton Rouge. It is in the sugar bel with forests and oil wells near by. Products o its industries are sugar, oars and ax handles boxes and egg cases, and metal castings. A series of locks connecting Bayou Plaquemin and the Mississippi River is a notable engineer ing feat. Water, power, and light systems ar publicly owned. Pop. (1930) 5,124; (1940) 5,049

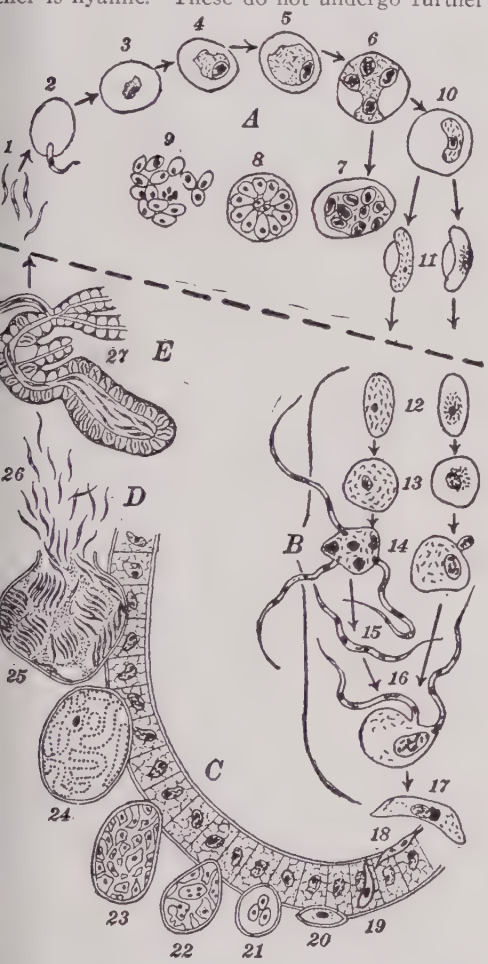
PLASKETT, John Stanley, Canadian as tronomer: b. near Woodstock, Ont., 17 Nov 1865; d. Victoria, B. C., Canada, 17 Oct. 194 One of the world's outstanding astronomers an former superintendent of the Dominion govern ment's astrophysical observatory at Victoria B. C., Dr. Plaskett was educated at the Univer sity of Toronto. He first worked as an enginee in Woodstock and later with the Edison Electri Company in Schenectady, N. Y., and at Sher brooke, Quebec, Canada. From 1890 to 1903 h was assistant in physics at Toronto Universit and in the latter year was appointed to th astronomical branch of the Department of th Interior at Ottawa, becoming astronomer at th Dominion Observatory in 1905. He became in terested in photographic spectroscopy and wa rated one of the leading experts in the measure ment of the motion of stars, temperatures, an physical conditions by means of the spectroscop In 1922 he discovered «Plaskett's Twins,» amon the largest stars ever found and previously be lieved to be but a single star. His works include 'Star Image in Spectroscopic Work'; 'Diffus Matter in Interstellar Space'; 'Rotation of th Galaxy'; and 'The Dimensions and Structur of the Galaxy.'

PLASMA, (1) *in mineralogy,* a leek-gree silicious mineral, found in angular pieces asso ciated with chalcedony. It is feebly translucen and has a somewhat oily lustre. (2) *In biolog* the liquid part of nutritive animal fluids, suc as blood, lymph or milk as distinguished fro the organized solids contained in them, as fo instance the corpuscles of the blood.

PLASMODIUM, a genus of sporozoa protozoa that contains the malarial organism

he genus belongs to the order *Hæmosporidia* hich contains highly specialized parasites dapted for life in the blood stream. There are ncluded three parasites of human malaria and lso a species which produces avian malaria. he young Plasmodium (see Fig. *A*) which is ctive and amoeboid occurs in the red blood orpuscles and after a period of growth, dur- ng which it attains rapidly the size of the orpuscle, the organism divides into numerous ores (*merozoites*) which scatter and attack ew blood cells. The process of schizogony just escribed is repeated until the infection has be- ome general. When a corpuscle breaks up and he merozoites are scattered a central residual ass of protoplasm loaded with black pigment *melanin*) is dispersed in the blood plasma.

At times the merozoites in the corpuscles de- elop into two new types, the gametes, one of hich is finely granular and opaque whereas the ther is hyaline. These do not undergo further change until the blood is withdrawn into the stomach of a mosquito, though the same changes follow its experimental removal to a culture tube. In the mosquito's stomach (see Fig. *B*) the motile microgametes are formed and one such fuses with a non-motile macrogamete after the latter has extruded a portion of its nuclear substance. There is formed by the union a motile ookinet which penetrates the stomach wall of the mosquito (see Fig. *C*), encysts and undergoes multiple division to form sporoblasts within which arise also by division sporozoites. The latter are very minute. Set free by rupture of the cystwall they wander to the proboscis and enter the salivary glands (see Fig. *E*) whence they are injected into a new human host when the mosquito bites. They attack the red cells at once and the life cycle begins anew.



e cycle of *Plasmodium falciparum*. *A*, Asexual cycle in human blood; 1, sporozoites injected by mosquito bite, 2-9 schizogony and reinfection of corpuscles; 10-11 origin of gametes. *B-E*, Sexual cycle in mosquito; *B*, in stomach, 12-17 growth and fusion of gametes; *C*, sporogony in wall of intestine, 18-25 formation of sporoblasts and of sporozoites in cysts; *D*, sporozoites in body cavity; *E*, sporozoites penetrating salivary gland and proboscis.
The dotted line across the figure separates stages in man (above) from those in mosquito (below).

Laveran in 1880 was the first to attach significance to the structures found in red blood cells in cases of malaria though the malarial organism had actually been seen and figured in 1843. Manson set forth distinctly in 1896 the part of the mosquito in transmitting the disease and a year later Ross followed in detail for the first time the fate of the parasites in the body of the mosquito. Malarial parasites have been cultivated *in vitro* by Bass and Johns.

The three species parasitic in man give rise to different and generally recognized types of malaria. *Plasmodium malariæ*, which extends farthest north and is not found in the tropics, is the cause of quartan fever. *Plasmodium vivax* gives rise to the tertian fever; it is widely distributed and not very dangerous. *Plasmodium falciparum*, the smallest of all three, produces the dangerous fevers known as the pernicious, tropical, quotidian or estivo-autumnal type; this type is epidemic only in the tropics and subtropics. Other varieties have been described though their independent character is not fully recognized.

PLASSEY, pläs'sē, India, a village on the Bhagirathi River, 96 miles north of Calcutta, celebrated in the history of India for the great victory gained by Clive over Suraj ud Dowlah, subahdar of Bengal, 23 June 1757, a victory which laid the foundation of British supremacy in India. The site of the battle is now covered by the river. See INDIA.

PLASTER OF PARIS, powdered gypsum as prepared for taking casts, molds, etc. If one part of powdered gypsum be mixed with two and a half parts of water, a thin pulp is formed, which after a time sets to a hard, compact mass. By adding a small quantity of lime to the moistened gypsum a very hard marble-like substance is obtained on setting. Substances other than lime are also employed for the purpose of rendering the mass hard and very compact; thus Parian cement consists of plaster of Paris mixed with borax; marble-cement is the same plaster mixed with alum and soda. See GYPSUM.

PLASTERING is the art of covering the surface of a wall or ceiling with lime or plaster in order to give it a smooth and uniform surface, and generally in interiors to fit it for painting or decoration. Technically the term plastering is used only when the plaster is spread over a screen of laths fixed to the wall. In modern usage this lath may be of perforated sheet metal, or a heavy paper board, called

plaster board, may be substituted for the wooden laths. The chief preparations used by plasterers are known as *coarse stuff, fine stuff, plasterer's putty,* and *gauged stuff.* The first of these is composed of sand and lime, mixed with long ox hair; the second is slaked lime, usually without hair; the third is not unlike the second; and gauged stuff is a mixture of plasterers' putty and plaster of Paris. Three kinds of plastering are distinguished, namely, one-coat (lath and lay), two-coat (lath, lay and set), and three-coat (lath, lay, float and set). In one-coat work a layer of coarse stuff is spread over the laths and pressed well into the spaces so as to form a *key* to hold the coat in place. When a second coat is to be applied, the first is not smoothed, but roughened with a birch-broom so as to retain the second one in place. The second coat consists of fine stuff, putty or gauged stuff. In plastering the interior of houses a first coat is laid on of coarse stuff, the process being known as *pricking-up.* The face of the first coat, which should be of considerable thickness, is troweled or indented diagonally with the point of a lath to form a key for the finishing coats. The second coat is applied to this when it is thoroughly dried. It consists of fine stuff, and is rubbed in with a flat board so as thoroughly to fill the indentations and cover the unequal surface of the first coat with a smooth and even one. In plastering walls great care must be taken to have the surface perfectly vertical. This second coat is called the floated coat, because wooden boards, known as floats, are used in rendering the surface plane. Before drying this coat is scraped with a birch-broom to form a key for the next. The setting coat is applied to the second after it has become perfectly dry. If the wall is to be papered this coat is of fine stuff. (See BUILDING; GYPSUM; LATHS). Consult: Bankart, G. P., 'Modern Plasterwork Construction, Casting and Fixing; Fibrous, Solid and Reinforced' (London 1926); and 'Modern Plaster Design' (ib. 1927); Eckel, E. C., 'Cements, Limes and Plasters' (1928); Lowndes, V. S., 'Plaster and Plastering' (1924); McVay, T. N., 'A Study of Hard Finish Gypsum Plasters' (Urbana, Ill. 1927); Savage, W. L., 'Practical Plastering' (London 1928).

PLASTERS, preparations for local application to the surface of the body, kept in place by any convenient wrapping of cotton, linen, silk, etc., or merely of paper and frequently with the aid of some adhesive substance. Plasters may be intended simply to give protection, support or warmth, as in the case of wounds, bruises or local weakness, or they may be actively medicinal. In most of the recognized medicinal plasters the adhesive property is due to the combination of oxide of lead with fatty acids, though india-rubber is also used. Olive-oil and litharge are used in the compound which most frequently forms their base. The 13 plasters of the United States Pharmacopœia are ammonia and mercury, arnica, belladonna, cantharides, capsicum, iron, isinglass, lead, mercury, opium, pitch, resin and soap. The numerous unofficial plasters are various in composition and in specific purpose and efficacy. The porous plaster made to stick very firmly to the skin has been popular. Plasters in the form of blisters are also largel used. See BLISTER.

PLASTICS. The modern plastics indu try deals chiefly with moldable materials manu factured from organic compounds, that is, con binations of carbon with hydrogen, oxyge nitrogen, and other elements. The inorgan molding materials, such as concretes, cement and ceramics, and also rubber, an organic sub stance, are not generally included within th scope of the plastics trade as it is known toda inasmuch as the industries utilizing these mater als are considerably older and were already ind vidually organized and developed prior to th advent of the newer plastics.

TYPES OF ORGANIC PLASTICS

The four principal types of organic plastic are: (1) synthetic resins; (2) natural resins (3) cellulose derivatives; and (4) protein sub stances. A brief description of each of thes groups will serve to indicate to the reader wh is unacquainted with this field the essenti characteristics of each type and the distributio of the various commercial plastics according t this classification.

Synthetic Resin Plastics.—Public interes has probably centered largely upon the synthet resin plastics because of their multiplicity an versatility. The chemist has been able to pro duce at will resinous materials having the hard ness of stone, the transparency of glass, the elas ticity of rubber, or the insulating ability of mic These synthetic resins, in combination with suita ble fillers, are readily molded into produc characterized by excellent strength, light weigh dimensional stability, and resistance to moistur moderate heat, sunlight, and other deterioratin factors. They lend themselves especially to th rapid manufacture of large quantities of accu rately sized parts by the application of heat an pressure to the material placed in suitable mol and to the use of original or imitative effects i a variety of colors. Some of the cheap raw ma terials used in their production include phen urea, formaldehyde, glycerol, phthalic anhydrid acetylene, and petroleum. Synthetic resin plastic are known commercially under such trade nam as Bakelite, Catalin, Beetle, Glyptal, and Vinylit They are used in an ever-growing variety of ap plications, such as electrical parts, automotiv parts, closures, containers, costume accessori including buttons, buckles, and jewelry, hard ware, table- and kitchenware, and miscellaneou novelties.

The powdered molding compositions are ge erally sold to custom molders who produce th finished parts. Casting resins and laminate resinous products, described in more detail late are, however, usually made into sheets, rods, tubes by the manufacturer of the resin. Blank are cut from these for the preparation of th finished product by machining operations.

Natural Resins.—These are more fami iarly known to the public by their comm names, such as shellac, rosin, asphalt, and pitc than by the proprietary names attached by ma ufacturers to molding compositions prepare from them. They are used in industry for th production of the fusible type of molded produ as distinguished from the infusible articl formed by some of the synthetic resins. Ho molding compositions are prepared by mixi shellac, rosin, and asphalts with suitable filler Compositions containing chiefly shellac as th

binder are used in electrical insulators for high-voltage equipment, in telephone parts, and in phonograph records. The terms *rosin* and *resin* are often confused. Rosin is a natural resin recovered as a solid residue after distillation of turpentine from pine tree extracts.

Cellulose Derivatives.—The third type of organic plastic, the cellulose derivatives, is probably the most widely used and best known of any of these materials. To this group belong celluloid plastics used for making toys, toiletware, pen and pencil barrels, and the like; cellulose acetate commonly used in the Celanese type of rayon, safety film, and in place of the slightly less expensive nitrated cellulose when nonflammability is desired; and regenerated cellulose, familiar to all as the wrapping material Cellophane and the common or viscose type of rayon.

The basic raw material, cellulose, is obtainable in fairly pure, fibrous condition as either ordinary cotton or pulped wood. Treatment with chemicals converts cellulose into compounds which are characterized by the ease with which they can be formed into desirable shapes. Cellulose plastics excel in toughness and are especially useful in thin sheets which have remarkable flexibility. These plastics conduct heat slowly and can be made substantially tasteless, odorless, and transparent. Their principal applications, in addition to those mentioned above, include photographic film, safety glass, flexible window material, artificial leather, airplane dopes, and lacquers.

Protein Plastics.—Such plastics are perhaps best known according to the source of the raw material—for example, casein from skimmed milk and soybean meal from soybeans. These protein substances are thoroughly kneaded into a colloidal mass, which is then formed into sheets, rods, or tubes by suitable presses or extrusion devices. The formed pieces are hardened by treatment with formaldehyde. The finished products, such as buttons, buckles, beads, and game counters, may be machined from blanks cut from the hardened material or may be shaped from the colloidal casein mass and then hardened. This latter process is now common practice because of the shorter curing time required for the thin pieces.

Fusible and Infusible Plastics

The plastics used in the molding industry may be divided into two groups, based on their behavior toward heat, as (1) thermoplastic and (2) thermosetting. The thermoplastic materials are permanently fusible, that is to say, they alternately melt or soften when heated and harden when cooled. If they are subjected to very high temperatures, vaporization or decomposition takes place. The cellulose derivatives, some synthetic resins, and most of the natural resins are examples of this type. The thermosetting plastics, on the other hand, may be made permanently infusible. This group is usually further subdivided into three stages on the basis of changes in physical and chemical properties. The product of stage (A) is called the initial condensation product and may be liquid or solid; it is both fusible and soluble. The intermediate or stage (B) product is insoluble and difficult to fuse, but it can be molded by the proper application of heat and pressure. This is the usual condition of the resin in the molding composition when it is received from the manufacturer. Further heating of this material, as in the process of molding, converts it to the final or stage (C) product, which has a permanent set and maximum hardness, strength, resistivity, and insolubility. Most of the molded products of synthetic resin composition which are on the market belong to the thermosetting type.

The Development of Plastics

A chronological survey of the development of plastics is presented in the following sections. By discussing them in the order of their appearance on the market a better idea of the underlying needs which led to their production and their relative importance in the plastics industry today will be obtained. The special properties which characterized each new material and which in many instances were there by design and not by mere chance alone will be described. The important uses which have been made of these various plastics will be recounted.

Cellulose Nitrate Plastic.—The oldest of the synthetic plastics is the cellulose nitrate or pyroxylin type. It is amazing that a material so hazardous to handle and so readily decomposed by heat has held an important place in the plastics industry for so many years. However, it has many unique properties which until recently have made it the best available thermoplastic material for many purposes. Alexander Parkes, an Englishman, prepared various articles from a solution of cellulose nitrate and camphor during the period 1855 to 1865, but John Wesley Hyatt, an American, is generally credited with being the first to attempt to work with cellulose nitrate as a plastic mass rather than in solution. He is said to have been motivated by a desire to find a substitute for ivory in the manufacture of billiard balls, in order to win a prize offered for that achievement. Although unsuccessful in obtaining the award, Hyatt with his brother, Isaiah S. Hyatt, took out a patent in 1869 for making solid collodion with very small quantities of solvent, dissolving the pyroxylin under pressure, thus effecting great economy of solvents and a saving of time. The Albany Dental Plate Company was organized in 1870 to handle the first application of the cellulose-nitrate-camphor plastic. By 28 Jan. 1871, the demand for the material for miscellaneous uses had become sufficiently great to bring about the formation of the Celluloid Manufacturing Company which moved in 1872 from Albany to Newark, its present location. Today Celluloid is only one of a number of trade names, such as Nixonoid and Pyralin, that are used to designate cellulose nitrate plastics produced by various firms in America.

Cellulose nitrate plastic was one of the first to be used in the automobile, being employed in sheet form as windows in the side curtains of early models. Its flexibility and nonfragility were important factors in this application, but its susceptibility in the transparent form to ultraviolet light resulted in rapid deterioration of these sheets. Typical applications of this plastic include bag frames, brushes, buckles, clock dials and crystals, drafting instruments, fountain pens, piano keys, shoe eyelets and lace tips, spectacle frames, toilet seats, tool handles, toothbrush handles, toys, and covers for wooden heels. The contributions of this first synthetic plastic to the plastics industry have been extensive and lasting. It not only paved the way for the advances which have been made in formulation and pigmentation of all thermoplastics, but it also supplied much of the mechanical and operative

means of manufacture and fabrication. It was the real pioneer in the development of the market for plastics and in many of their uses.

Shellac Plastic.—The next plastic to become of importance in the United States was shellac molding composition. Shellac is of natural origin, being produced by an insect which lives upon certain trees in India and Southern Asia, and has been known and utilized for many centuries for various purposes, such as a component of sealing waxes, polishes, and varnishes. In 1888, Emile Berliner (q.v.) had worked out the details of the method that made it possible to engrave a sound groove on a flat disk, but means of duplicating these recordings in large numbers remained to be perfected. He tried both cellulose nitrate and hard rubber, but neither of these materials was satisfactory for his purpose. In 1895 he turned to a plastic composition containing shellac as a binder, and soon the technique of molding shellac base phonograph records was under full development. The properties which make it especially suitable for the manufacture of records are ease of molding, toughness, hardness, fidelity of reproduction, low cost, and the possibility of re-using the scrap material. Developments since about 1920 have been primarily in its application as a resinous binder for cloth, paper, silk, mica, and other electrical insulating components.

Bitumen Plastic.—The third plastic to become industrially important in America was the bituminous type, more commonly known as cold-molded. Emile Hemming was the pioneer in its development in the United States, and introduced it on the market in 1909. The raw materials used in the preparation of cold-molded plastics are asbestos, asphalts, coal tar, stearin pitches, natural and synthetic resins, and oils. The asbestos in the proportion of 70 to 80 per cent contributes the body of the material and the bituminous or resinous ingredients in the proportion of 20 to 30 per cent function as the binder. The molding is done at or near room temperature, hence the name cold-molded. The pieces are removed immediately from the mold and cured in electrically heated ovens to drive off the volatile constituents, oxidize or polymerize the oils or resins, and so transform the plastic into a hard, infusible state. The cold-molding operation is faster than hot-compression molding since the curing is not done in the mold, but the higher pressures required for cold molding and greater abrasive action of the mineral filler make mold maintenance much more of a problem than it is in hot molding. Typical applications of cold-molded plastics include connector plugs on household electrical equipment, heat-resistant handles and knobs for cooking utensils, and battery boxes.

Phenol-Formaldehyde Resin.—The first and still the most versatile of the commercial synthetic resins, the phenol-formaldehyde condensation product, was described and patented in 1909 by Leo Hendrik Baekeland. Thus, both the original thermoplastic material, cellulose nitrate plastic, and the original thermosetting material, phenol-formaldehyde resin, were first developed commercially in America. Johann Friedrich Adolf Baeyer had reported in 1872 that the reaction between phenols and aldehydes leads to the formation of resins, but no products of industrial interest were obtained for the next thirty-five years because of the inability of investigators to control the reaction. Baekeland provided this essential feature, and described a technique for converting this resin in a relatively short time into a molded article of excellent mechanical and electrical properties. The basic patents covering the preparation of solutions of this resin and their use in impregnating fibrous sheets to make laminated products were issued to Baekeland in 1910 and 1912, respectively.

The manufacture of Bakelite phenolic plastics was begun in Baekeland's Yonkers, N. Y., laboratory in 1907. The General Bakelite Company was organized in 1910 and was merged in 1922 with the Condensite Company and the Redmanol Chemical Products Company into the Bakelite Corporation. Since the expiration of the basic patent in 1926, many other firms have marketed phenolic resins under other trade names, for example, Durez and Resinox.

An important modification of this general type of resin is the use of furfural, produced from waste oat hulls, in place of formaldehyde for the condensation reaction with phenol.

Typical applications of phenolic plastics include distributor heads, coil parts, switches, and related elements in automobiles and airplanes, camera cases and other housings, corrosion-resistant apparatus, and telephone and radio equipment. In combination with paper and fabrics, phenolic resin produces laminated products which are used for gears, bearings, trays, table tops, refrigerator doors, wall coverings, doors, and counter and cabinet paneling.

Casein Plastic.—The discovery of the tough, insoluble, hornlike mass produced by the action of formaldehyde on milk casein is said to have been made by two men who were looking for a composition material to replace slate for blackboards. These two men, Wilhelm Krische and Adolph Spitteler, began production of casein plastic about 1900 in Germany and France, respectively, using the trade name Galalith, meaning «milk stone.» It was 1919 before successful production in America was realized, and its use has been limited because of the marked variations in climate throughout the year, which lead to warping and cracking of this plastic. Its use is confined to small articles like beads, buckles, buttons, game counters, novelties, and trimming accessories.

Cellulose Acetate Plastic.—A period of very active development of new plastic materials in America started with the appearance of cellulose acetate in the form of sheets, rods, and tubes in 1927. The firm which pioneered in the development of pyroxylin plastic also introduced cellulose acetate plastics to the American market. This was accomplished by a combination in 1927 of the Celluloid Company with the Celanese Corporation, already a large producer and consumer of cellulose acetate for rayon manufacture. In 1929 the first cellulose acetate molding powder was marketed for use in compression molding. The appearance of the injection molding press in the early 1930's greatly increased the speed with which molded articles could be produced with this thermoplastic material. Cellulose acetate plastics and molding powders are now available from several commercial sources and have outstripped the cellulose nitrate type in the quantity and dollar value of annual production.

Cellulose acetate very early found use as a safety photographic film to replace the hazardous cellulose nitrate product. Many of the appli-

PLASTICS

cations of this plastic—for example, protective goggles, oil gauges, screw driver handles, and flexible window material—have been brought about by the safety factor introduced by its high resistance to impact. Some of the trade names for cellulose acetate plastics are Lumarith, Plastacele, and Tenite I.

Urea-Formaldehyde Plastics.—The appearance of the urea-formaldehyde resinous molding compound on the United States market in 1929 meant the extension of unlimited color possibilities into the field of thermosetting molding. Two such urea molding powders, Aldur and Beetle, became available that year, while another, Plaskon, was marketed in 1931. Extensive use of urea plastics in the illuminating industry has resulted from their efficiency in providing a diffused light, plus their lightness in weight and shock resistance. The fact that they are insoluble, infusible, tasteless, and generally chemically inert has made possible their successful use for bottle closures and lightweight tableware. The urea-formaldehyde resins have also been introduced into the field of laminated plastics as paneling and trim for bathrooms, libraries, and hotel and theater lobbies, in order to take advantage of the many stable colors in which they are produced.

Cast Phenolic Plastics.—Phenolic resin for casting is prepared in the form of a viscous syrup which is poured into lead or rubber molds and hardened by heating. Products were made as early as 1910 from cast Bakelite resinoids, but in their modern form cast phenolics were first introduced in America in 1928. Cast phenolics are known by such trade names as Catalin, Gemstone, and Marblette. They owe their popularity quite largely to their beauty and decorative value, and this type of plastic is often referred to as the «gem of modern industry.» Typical applications include advertising signs and displays, clock cases, game counters and pieces, radio housings, and lighting fixtures. More recently their use in industrial adhesives and laminating varnishes has been promoted.

Vinyl Resin Plastics.—Resins formed by co-polymerization of vinyl chloride and vinyl acetate were first made in the United States by the Carbide and Carbon Chemicals Corporation under the trade name Vinylite in 1928. This type of resin has found its most important uses in phonograph records, coatings for concrete and metals, can linings, adhesives, and electrical insulation. In a highly plasticized form, it is now employed for making transparent belts, suspenders, and shoe uppers. The resins formed from the individual esters—vinyl chloride and vinyl acetate—are also important commercially for the manufacture of wire and cable coverings, coated fabrics, adhesives, and plastic wood-filled compositions. Polyvinyl butyral plastic has been found to be outstandingly superior for use as the binder in laminated glass for the automotive and aircraft industries. Three plants were built for its manufacture during 1937 and 1938, and it has now largely supplanted cellulose acetate in this particular application. Production of vinylidene chloride resin was initiated by the Dow Chemical Company in 1939.

Styrene Resin.—In 1937 the Dow Chemical Company made available a synthetic monomeric styrene of high purity and a corresponding polymeric product, Styron, in clear, transparent form. The Bakelite corporation also started to manufacture Bakelite polystyrene this same year. The most significant properties of polystyrene are its low power factor and practically zero water absorption. These remarkable properties make styrene resin exceptionally well suited for radio-frequency insulation. Its transparency and chemical resistance are responsible for most of its other uses, such as bottle closures, refrigerator trim, automotive accessories, and indirect lighting mileage and other indicators.

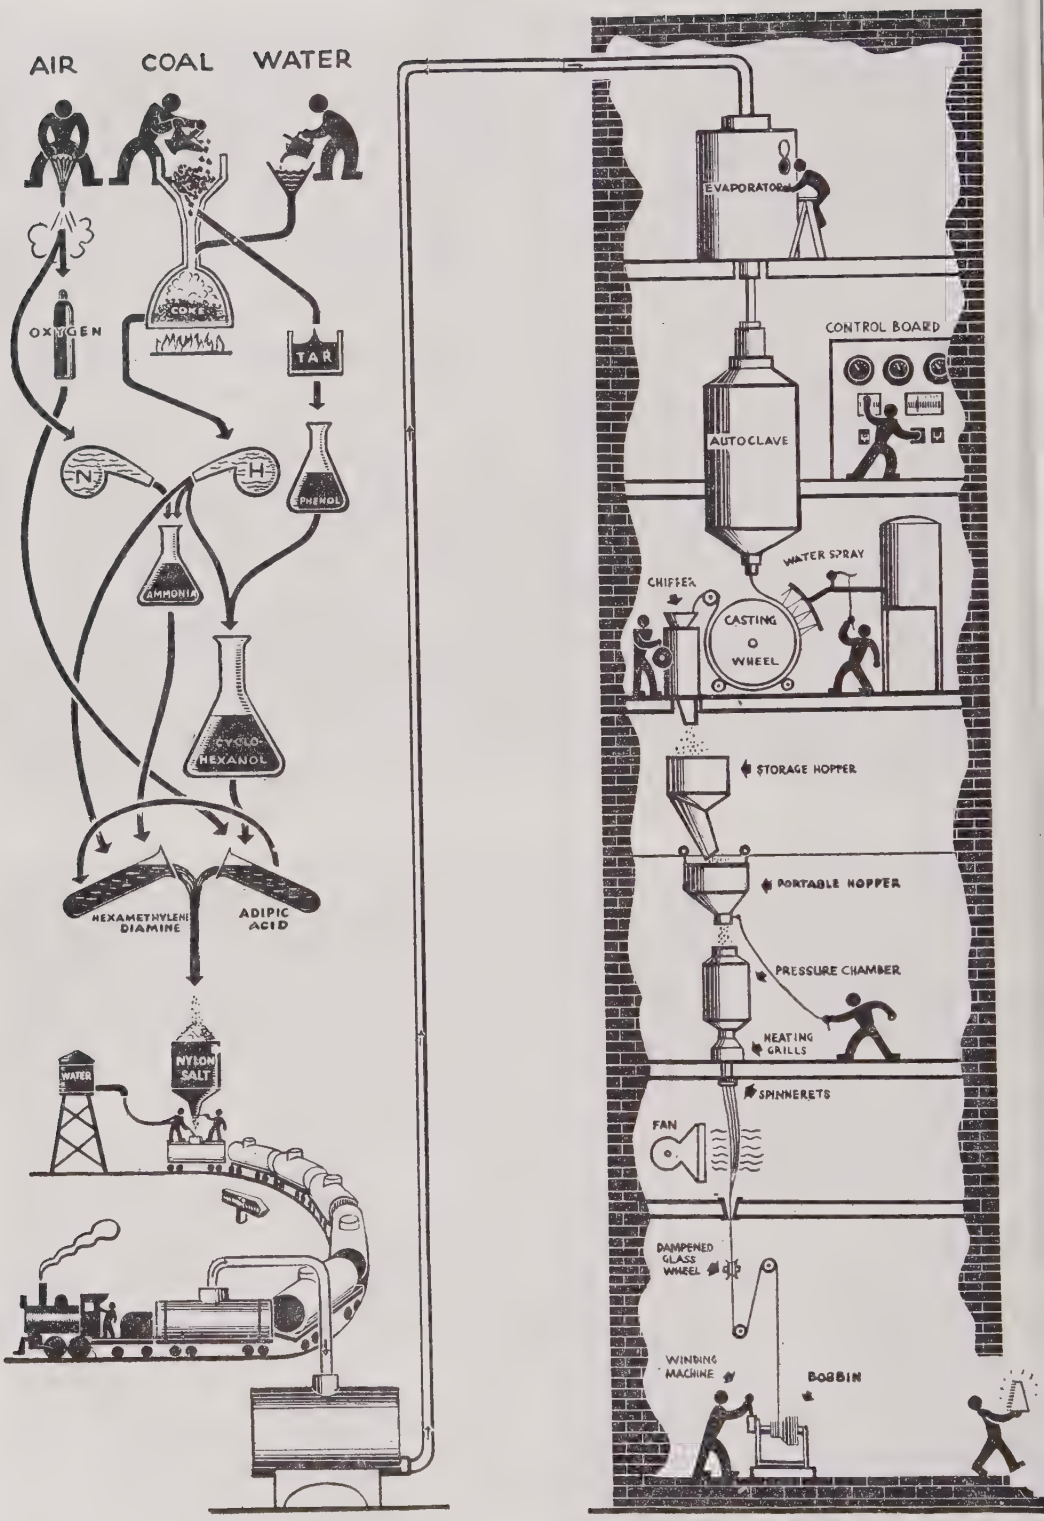
Acrylic Resins.—The acrylic resins were first prepared industrially in America in 1931 for use in coatings and as a binder for laminated glass. The better known and very interesting methyl methacrylate resin is a product of more recent origin. The cast resin, called Plexiglas and Lucite respectively by its two manufacturers, reached the production stage during 1937–38. The airplane industry has found these cast sheets particularly well adapted to their requirements for gun turret and cockpit enclosures because of their lightness, weathering resistance, nonfragility, and clarity. The resin's high internal reflection makes possible spectacular and useful lighting effects in edge-lighted signs and dental and surgical instruments. This type of resin has been found to be pre-eminently suited for dentures. Its optical qualities make it suitable for spectacle and camera lenses and for reflectors for indirect highway lighting.

Cellulose Acetate Butyrate.—The Hercules Powder Company introduced this material in 1932 as a protective coating base. The Tennessee Eastman Corporation started manufacture of a cellulose acetate butyrate molding composition in 1938 and designated it as Tenite II, the original Tenite being their cellulose acetate molding compound.

Cellulose acetate butyrate compositions are superior to cellulose acetate plastics in weathering resistance and in freedom from warping. The requisite plasticity can be produced with a relatively low percentage of plasticizer and with comparatively nonvolatile and water-insoluble plasticizers. The applications of cellulose acetate butyrate plastic are primarily such as result from its combination of toughness and resistance to weathering, for example, woven furniture for exterior use, automobile accessories, and fishermen's equipment.

Ethylcellulose.—The first cellulose ether to be made commercially in America was ethylcellulose. The Hercules Powder Company began making it in 1935 and the Dow Chemical Company undertook its manufacture in 1937, marketing their product under the trade name Ethocel. Ethylcellulose plastic had not in 1942 come into general use for molded parts. Its chief applications to that date had been in protective coatings, adhesives, paper and fabric coatings, wire insulation, and extruded strip. Another cellulose ether, methylcellulose, was announced by the Dow Chemical Company late in 1939. Methocel, as it is called, is water soluble, odorless, tasteless, and nontoxic. It yields films which are greaseproof and highly flexible.

Lignin Plastics.—The utilization of waste wood and sawdust for the production of molding compositions has been the objective of a considerable number of investigators since about 1930. Wood contains approximately 25 per cent of lignin, a complex and highly reactive



Courtesy E. I. Du Pont De Nemours & Co. (Inc.)

Pictorial diagram showing how nylon yarn is manufactured.

organic compound. In 1937 a lignin plastic first became available under the trade name Benaloid, manufactured by the Masonite Corporation. The development of lignin molding compositions of both the thermoplastic and thermosetting types was announced in 1939 by the Marathon Chemical Company. The low cost of the necessary ingredients makes this plastic of interest for industrial applications which require large quantities of material, such as certain automotive parts, building units, furniture, and wall paneling.

Alkyd Resins.—These are used primarily as coating materials which, incidentally, are the largest single outlet for synthetic resins. They are made by the reaction of phthalic anhydride or maleic anhydride with glycercol or other polyhydric alcohols. Finishes based on such resins as Glyptal, Dulux, and Rezyl are characterized by rapidity of drying, good durability outdoors, excellent flexibility, tenacious adhesion, and electrical insulating qualities. These resins during the 1930's replaced the pyroxylin lacquers to a large extent for finishing the bodies and fenders of motor cars.

Nylon Resins.—These polyamide resins are made from polyamines and polybasic acids. The basic raw materials for nylon resins are castor oil, from which sebacic acid (a ten-carbon dibasic acid) is obtained, and phenol which, by hydrogenation and oxidation, yields adipic acid (a six-carbon dibasic acid). Hexamethylene diamine made from adipic acid, and decamethylene diamine made from sebacic acid are typical diamines used in synthesizing these resins. Nylon resin was made available on a large scale by E. I. duPont de Nemours and Company, Inc., during 1940. It quickly proved its suitability for hosiery to manufacturer and consumer alike and was accepted as a superior bristle material for toothbrushes, hair brushes, and brushes for miscellaneous industrial purposes. It has proved a tremendous military asset to the United States to have nylon available to replace silk in the manufacture of parachutes.

Coumarone-Indene Resins.—The manufacture of this type of resin from certain coal-tar distillates was begun in 1919 by the Barrett Company using the trade name Cumar. In 1929 the Neville Company marketed such resins as Nevindene. The low softening points and brittleness of these resins have restricted their use to serving as plasticizing agents and tackifiers with various organic binding materials in rubber compounding, floor tile compositions, and other industrial applications.

Molding Technique

The discovery of the fundamental principle involved in the operation of the hydraulic press is generally conceded to have been made by Blaise Pascal in 1653. The adaptation of this principle to a practical machine is credited to Joseph Bramah in 1795. Little industrial use was made of it until after the discovery of the vulcanization of rubber by Charles Goodyear in 1839. A simple hydraulic rod-type press, between the platens of which a two-piece mold was inserted, was developed for handling the manufacture of rubber products and was subsequently employed for molding the thermoplastics.

The advent of the phenolic thermosetting resin in 1909 provided the stimulus for introducing features in the compression molding press which would increase the output from a given mold. However, realization of the fully automatic compression molding press came in the late 1930's. These presses perform all the operations of routine molding of thermosetting plastics, consisting of measuring the charge of molding powder, preheating it, loading it into cavities, closing the mold, opening it slightly for breathing, that is, expulsion of gases, closing it again for a predetermined curing period, opening the mold, ejecting the finished pieces, blowing flash from the cavities and plungers, and then repeating this cycle hundreds and thousands of times with the only manual labor required being to keep the hopper supplied with the molding powder.

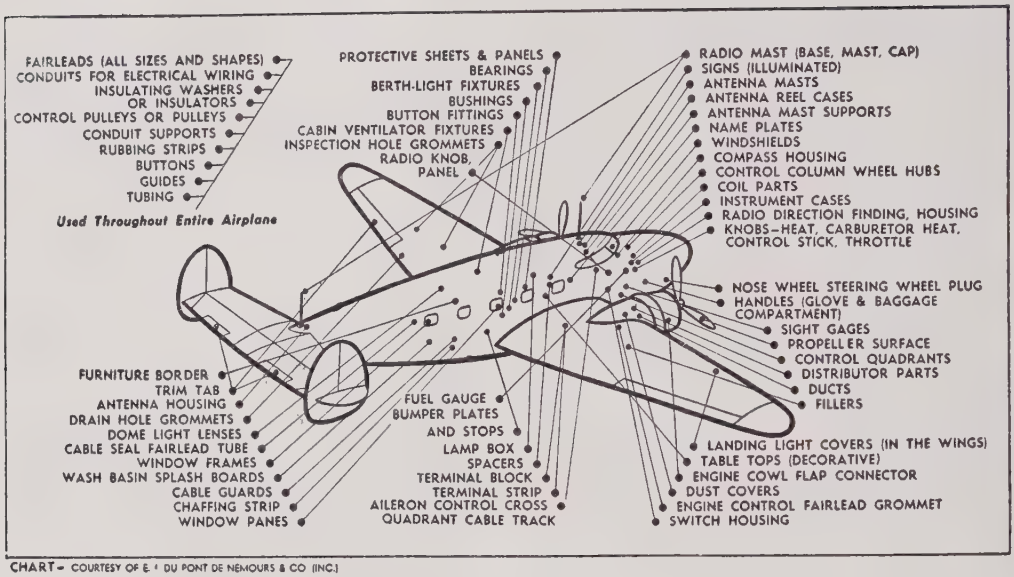
The original conception of the injection molding principle is commonly attributed to Edmond Pelouze, who in 1856 developed a die-casting machine for forcing molten metal into a die by mechanical or hydraulic means. The industrial history of the injection molding machine for plastics in the United States seems almost incredible when one looks at the huge model capable of taking a mold three by four feet in cross section and turning out four 36-ounce moldings every minute.

The need for the injection molding machine came with the commercial development in 1929 of the heat-stable thermoplastic molding material, cellulose acetate, which required an uneconomical chilling period when molded by conventional compression methods. The cellulose acetate plastic, however, unlike the older cellulose nitrate type, could be kept hot for a relatively long period in a heating chamber and injected hot into a cold mold wherein it cooled in a few seconds to a temperature at which it would maintain its shape and hence could be ejected from the mold.

At the close of 1935 there were approximately seventy-five injection molding machines in use in America, mostly of one-half to one and one-half ounces per cycle capacity and suitable only for the molding of small articles, such as buttons, pocket combs, and costume jewelry. The demands of molders for machines of increased capacity and sturdier construction to be used for turning out parts for industrial applications led domestic press manufacturers to construct injection molding machines with radical changes in the design of the heating cylinders, spreading devices, injection plungers, and clamping devices. By combining several cylinders, each feeding into a different inlet in the same mold, parts of considerable size weighing up to 36 ounces can be produced. At the close of 1942 there were in the United States 1,000 injection molding presses, 11,000 compression presses, 550 preform presses, and a rapidly growing number of plastic extruding machines.

Recent Developments

The keynote in the plastics industry during the Second World War has, of course, been the rapid development of materials and fabricated parts suitable for use in military equipment. Aircraft manufacturers use molded, laminated, and formed plastics for outstanding applications in gun turrets, nose sections, cabin ventilators, radio antenna masts and loop housings, and navigation instruments. Fabrication of aircraft structures by the rubber-bag molding process has been in successful operation in a number of plants in the United States and Canada. It has been demonstrated that this



Plastic Parts on Airplanes.

is a practical method for producing aeroplanes using materials and labor which are more readily available than those required for metal aircraft. In ordnance, plastics have been used for molding mortar shell fuses, ogives, and grips for pistols, bayonets, and machine guns. In gas masks many of the parts are made of thermoplastics, including lenses, eye frames, Y tubes, and valve guards. The Quartermaster Corps employs plastics for the new army helmet liner, razor cases, combat whistles, combs, mess kit knife handles, insignia, and many other items of the hundreds which are handled by this supply unit. The navy uses them for electrical insulation, instrument housings, reflectors, etc., on board the fleet. The Signal Corps depends on plastics in its field telephone and radio equipment, lighting apparatus, and for containing the important messages entrusted to carrier pigeons.

A record-breaking production effort was required to meet these new demands on the plastics industry. The total production of synthetic resins in 1941 was about 438,000,000 pounds, an increase of 58 per cent over 1940. This included some 146,000,000 pounds of phenolic resins, 138,000,000 pounds of alkyd resins, and 35,000,000 pounds of urea resins. The total output of cellulose plastics reached a new high of over 53,000,000 pounds in 1941, the 50 per cent gain over 1940 being of the same order as that for the synthetic group. Particularly noteworthy was the production of cellulose acetate molding composition, which practically doubled during 1941, the total of this material exceeding 30,000,000 pounds.

The outstanding advance in molding technique has been the development in continuous extrusion. This is providing plastics in convenient shapes to replace aluminum, stainless steel, and other metals needed for war purposes. The process differs from the former technique employed in making rods and tubes in that the composition hardens simply by cooling, whereas previously a solvent had to be added to obtain proper flow and this solvent had to be removed in a seasoning process. Fairly intricate shapes can now be made on a commercial scale from the various thermoplastics. Extruded plastics will be particularly applicable in furniture and cabinet trim, interior decoration, upholstery for transportation and theater seats, and in the preparation of fabrics of unusual strength and resiliency.

Synthetic resins recently have become available in the United States for use in water softening and purification, recovery of valuable substances from solution, and removal of dissolved salts from biological and pharmaceutical preparations. This function of synthetic resins as ion exchangers focuses attention upon their chemical properties in contrast to previous emphasis on strength, hardness, inertness, and color.

During the war many new developments in synthetic resins must remain in the laboratory because of lack of plants, personnel, and materials to undertake their commercial production. Those new materials which appear resulted from efforts to provide plastics based on readily available natural products, such as lignin, soybean, and rosin derivatives. The experience gained in engineering new materials and applications under wartime conditions will be valuable as a springboard for still greater strides by this industry in the postwar period.

Chief, Organic Plastics Section, National Bureau of Standards; Technical Editor, Modern Plastics.

PLASTID. A plastid may be defined as a differentiated portion of the plant protoplasm which is not formed *de novo,* but arises from the division of a pre-existing plastid. Plastids are denser than the surrounding protoplasm and the interior is denser than the surface. There is no surrounding membrane. The shape is generally spherical or oval (Fig. 1), but many plants have very striking plastids, as in case of the *alga,* Spirogyra (Fig. 2). When plastids are colorless, they are called *leucoplasts,* or *leucoplastids;* when colored, they are called *chromatophores.* When chromatophores are green, they are called *chloroplasts;* when they have any color other than green, they are *chromoplasts.* However, most botanists do not use so many names, but call all the colorless plastids leucoplasts and all the colored ones chromatophores. In all cases, the ground substance of the plastid is colorless, but it contains droplets of an oily substance which is green, yellow, orange, red or brown, as the case may be. Plastids near the surface are likely to develop chlorophyll, a green oily substance of the utmost importance in plant life; while plastids more deeply placed are likely to remain as colorless leucoplasts whose principal function is to produce starch. However, a leucoplast may become a chloroplast, as when potatoes are exposed to the light and become green, and they

FIG. 3.— Sectional view of a cell of an onion root tip showing thread-like mitochondira. All highly magnified.

again become leucoplasts when the potatoes are kept in the dark. Chlorophyll-bearing plastids usually contain also some very small grains of starch. Such starch grains are the first visible products of assimilation. Reserve starch, like the large starch grains of the potato, are formed inside the leucoplast and become so large that the leucoplast is stretched until it is only a very thin membrane surrounding the conspicuous starch grain. Botanists are not entirely agreed as to whether the plastid may originate *de novo* or not. The weight of authority is on the side of those who claim that the plastid is a permanent organ which arises only by the division of a previous plastid, as already indicated in our definition. That plastids divide and that an unbroken series can be traced throughout the greater part of the life history no one disputes; but in some phases of the life history, the most critical methods give no convincing demonstration of the presence of a plastid. In recent years, peculiar structures, called *mitochondria,* many of which resemble various forms of bacteria, have been claimed to develop into plastids (Fig. 3). This subject is still under vigorous investigation. Consult Mayer, A., 'Untersuchungen über die Stärkekörner'; Schimper, A. F. W., 'Uber die Entwickelung der Chlorophyllkörner und Farbkörper' (*Botanische Zeitung,* Vol. XLI, 1883, p. 105); Cavers, F., «Chondriosomes and Their Significance» (in 'New Phytologist,' Vol. XXXI, p. 170, 1914).

CHARLES J. CHAMBERLAIN.

PLATA, Rio de la, rē'ō dā lä plä'tä (silver river), or **River Plate,** a great estuary of South America, lying between Uruguay and Argentina, the union of the Paraná and Uruguay rivers (qq.v.). With these rivers it may be considered the second great river system of South America which drains the so-called La Plata states, namely, Argentina, Uruguay, Paraguay, southeastern Bolivia and southern Brazil. But the Plata itself is merely the estuary of this system and it is impossible to mark the point where it empties into the ocean, as the «river» is 170 miles wide between Cape San Antonio and Cape Santa Maria. The volume of the river is great, in spite of its shallowness, and its current is perceptible 150 miles out to sea. The broadest river-mouth of the world, the Plata measures 25 miles across at Buenos Aires and more than 60 at Montevideo, where the only harbor of the whole basin is situated. At both Buenos Aires and the port of La Plata immense piers or breakwaters are built out far into the water. The entry from the ocean is dangerous and is guarded by lighthouses and lightships. The course of the La Plata system was explored by Day in 1853 and by Page 1853–56.

PLATÆA, plă-tē'ą, ancient city of Bœotia in Greece, on the frontier of Attica, beneath Mount Cithæron and south of the Asopus River, at the head of the Gulf of Corinth. The famous temples of Hera and of Athena Areia with one of Phidias' colossal statues and paintings by Polygnotus were situated here. Its inhabitants were probably of Ionian stock. In 519 they made a treaty of alliance with Athens and at Marathon 1,000 Platæans shared in the victory. Their city was burned by the Persians in 479 and in September of the same year the Persian army was defeated here by the Platæans, Athenians and Spartans in a bloody battle, in which Mardonius, leader of the forces, left for the conquest of Greece after Salamis, took the offensive after the armies had been face to face for a fortnight and was killed with almost his entire army. The Platæans were highly honored by their allies for their part in this great battle and their independence was guaranteed by all the Greek states. But in the Peloponnesian War Platæa sided with Athens and was nearly betrayed (431) by a body of Thebans who attempted to destroy the city. In 429 the Spartan army of Archidamus attacked the city, from which all the non-combatants save 110 women had been sent to Athens. The 480 who remained (80 Athenians)

withstood all assaults, so that the Spartans had to be satisfied with a thorough blockade, in the second year of which the city was taken and its defenders killed, except a gallant party of 212 which had cut its way through the Spartan lines. The city was rebuilt and reoccupied by its people in 387, only to be destroyed again in 372 by the Thebans. It was again restored after the battle of Chæronea. A portion of the ancient city wall is still extant. Consult files of the *American Journal of Archæology.*

PLATE ARMOR. In general it may be said that at first all plate armor used was for reinforcing mail or other armor. The full panoply (cap-à-pied) was in use by the middle of the 15th century. The early period produced the finest pieces; the 16th century showed commencement of decline as to protective purposes. Then fire-arms caused the disuse of one piece after the other as affording too little protection. By the 18th century armor had become a ceremonial gear and was valued according to its metalworkers' and goldsmiths' decorative features. For historic purposes perhaps Ashdown's period division is as well suited as any, and is used in this description.

Studded and Splinted Period (1335–60.)—This is a transition era in which «reinforced» chain-mail (see CHAIN-ARMOR) came into vogue. The bascinet (headpiece) was of plate with visor attached (see HELMETS), and in some cases with a neck-plate riveted to the headpiece. Demi-brassarts were used to protect the upper arm.

The Camail and Jupon Period (1360–1410).—The sleeveless cloth jupon (surcoat) was worn over a swelling breastplate, under which was the hauberk. The bascinet was tall and conical with visor (*snout-faced* visors belong to this period) and attached to the camail; the Italian barbute was used now. (See HELMETS).

Surcoatless Period (1410–30).—In this period arrives the full panoply of plate free from textile; even the camail disappeared. It was replaced by a plate gorget upon which the bascinet rested. The breastplate is now worn outside and is «globose» and has a back-plate (*dossiere*). Overlapping steel lames were attached below the breastplate and were termed *taces.*

Tabard Period (1430–1500).—These were years of war and armor improved in defensive power. The pieces became not only more completely protective but the metal was better tempered till offensive arms, even guns, found trouble in penetrating it. It was a period of evolving frequent changes; the tabard alone was constant, whence the use of the term for the time. The tabard was a sleeved surcoat usually decorated with the wearer's armorial bearings. Till 1450 the bascinet continued in a very short time to give place to the armet. The body was protected with the «globose» breastplate till about 1450 when it was reinforced with the «demi-placcate» (or *pansière*), a plate rising from the waist and curving upward to a point in the centre of the chest. Armhole gussets were now rigid or turned back. Backplates (*dossières*) about 1450 were formed of several pieces. Epaulières and brassarts for the right arm were laminated for rapid sword action after shivering the lance. The bridle (left) arm wore extra thick plates and reinforcements of many kinds.

Transition Period (1500–25).—The closed helmet (*armet*) came into more general use and a skirt of chain-mail (a characteristic of this period) was worn. The gorget was made up of laminated plates and extended over the chest and down the back. The «standard» or collar of mail came into vogue end of the period. The breastplate was «globose,» usually with taces of one or more lames. Pauldrons were reduced, less angular and composed of overlapping steel lames, a pike guard (*passe-garde*) was usually on top.

Maximilian Armor (1525–1600).—So termed from the name of the emperor (1459–1519), also has been termed «late Gothic.» The surface is adorned with close, narrow flutings (after that day's fashion in dress) or channelings. The vogue began to fall off after 1540. It is more solid and less flexible than the former style. Breastplates are shorter and rounded out more. The left pauldron is usually larger than the right. Sollerets are of the square «bear paw» or «cow mouth» toe. The burgonet, morion, armet and cabasset (see HELMETS) were worn in this period.

Half Armor Period (from 1600).—The defensive quality of armor had passed in the former period; this period shows no full panoply but just a few uncouth «boiler-plate» pieces used as some protection against pistol shots, etc. The «three-quarter» suit contained, however, much of the cap-à-pied set except leg-armor (jambarts and sabbatons). Gradually armor parts were being discarded, some officers using only a cuirass over a «buff» (leather) coat; this, in Charles I's reign, was so common for entire regiments as to cause them to be termed «cuirassiers.»

PLATE GLASS. See GLASS, VARIETIES OF.

PLATE GLASS INSURANCE. After the repeal of the tax on glass windows in England in 1845 the glass industry took a great upward start, and in 1852 the Plate Glass Insurance Company was founded in London. The business spread rapidly; branches were established in New York and Australia, and the General Indemnity Insurance Company of London (1853) included a «Plate Glass» branch in its operations. Another company started a «Household Glass Department,» which insured mirrors, glass panels, chandeliers and windows, but not skylights. From these beginnings has grown an almost world-wide branch of financial activity in which the actuarial calculations of risk have been reduced nearly to an exact science. The liabilities can be fixed to a degree of exactitude that does not obtain in any other form of indemnity. Losses are adjusted by replacing the damaged property by paying an indemnity to the assured equal in amount to what it would have cost the company to repair the damage.

PLATE-MARKS. See HALL-MARKS.

PLATE AND PLATED WARE. The terms gold plate and silver plate are properly applied to articles or utensils of approximately solid metal, for use in the household or in religious ceremonials or purely for decorative purposes, as a prize cup. Articles of this character have from the remotest times and among all civilized nations been highly prized, and from their durability, intrinsic value and the beautiful forms into which they are often wrought have been esteemed the most precious heirlooms, and been held among the choicest family treasures through successive generations. The richest treasures of the temple of Solomon were of gold and silver plate, and such constituted the untold wealth taken by the Spanish conquerors of Peru from the ancient Incas. Though modern art has scarcely carried the manufacture of plate to higher perfection than that attained by skilful workmen of past centuries, it has succeeded in producing substitutes for it in what is called plated manufacture equally useful and almost as beautiful as the genuine plate, at prices that place within reach of those of moderate means what constitutes the luxuries of the rich. In the United States the industry of making silverware was begun by John Dixwell, Andrew Tyler and Edward Winslow of New England, and later Paul Revere, George Ridcout and Richard Van Dyke made silverware in New York before the Revolution. Later Rogers of Connecticut was a prominent manufacturer. He developed electroplating methods, and also achieved an enviable reputation for using the amount of silver that he guaranteed to put on. Thus the name of Rogers became a hall-mark of quality, and in the course of time there were four concerns making Rogers plated ware. Meriden, Conn., and Providence, R. I., are centres of the plating industry. See ELECTRO-METALLURGY.

PLATING. See ELECTROPLATING; PLATE AND PLATED WARE.

PLATINIRIDIUM, a native alloy of platinum and iridium in varying proportions. It is found in small grains and crystals associated with native platinum.

PLATINUM. The first published notice of platinum is contained in the 'Relación historica del viage á la América Meridional,' issued in Madrid in 1748, wherein Don Antonio de Ulloa, one of the members of a French expedition for the measurement of an arc of the meridian, records his observation of the metal about 1735, in the district of Chocó, in what is now the Republic of Colombia. Here it bore the name «platina del Pinto» as it had been discovered in washings on the Rio Pinto; the name «platina» properly signifies «little silver.» In 1741 Dr. William Brownrigg received in London some specimens of the ore, sent to him from Jamaica by his relative, Charles Wood, who in turn had received them from the South American port of Cartagena, but had not been able to learn their exact origin. Wood stated that the Spaniards must have learned the art of fusing it, as they had already made numerous ornamental objects of it, such as sword-hilts, buckles, snuff-boxes, etc. Hence it appears evident that they must have discovered the metal many years before the date when it was first seen by Ulloa. The earliest scientific determination of platinum was made almost contemporaneously by Dr. Brownrigg, whose results were communicated to the Royal Society through Sir William Watson in 1751, and by the Swedish chemist Theophilus Scheffer, who laid his results in the same year before the Academy of Sciences in Stockholm. The latter received his specimens from Madrid, through a friend named Rodenskiæld. After pronouncing it to be «a perfect metal, as stable as gold or silver,» Scheffer proceeds to declare that «its nature most closely approaches that of gold,» from which it differed, however, by its tenacity, color, hardness and the degree of heat necessary for its fusion. The name «white gold» was chosen as a designation for platinum in the earliest known volume treating exclusively of it, published in Paris in 1758, and believed to have been written by Jean Morin, at one time professor of chemistry in a college at Chartres, France.* This little work gives French translations of all the scant platinum literature extant at that time. The use of platinum in the making of gold counterfeits is alluded to in the 'Encyclopédie' of Diderot and d'Alembert, published in 1774, wherein it is stated that some Hollanders on the South American coast had been deceived by having spurious gold ingots largely composed of platinum passed off on them. For this they took summary vengeance, as on their next voyage to the coast they seized the offending Spaniards and strung them up to the yard-arms of the Dutch ships. At about the same period, or not long after, a number of Spanish doubloons of platinum, with a thin plating of gold, were struck and successfully passed for a time. As platinum was then many times less valuable than gold such counterfeits realized a handsome profit for their dishonest fabri-

* L'Or blanc où le huitième métal (Paris 1758).

cators, but to-day one of these counterfeit doubloons, the gold value of which if genuine would be about $8, would be intrinsically worth as much as $40. In the early part of the last century a number of similar counterfeits of United States $10 and $20 gold coins were made; several of which found their way to the Philadelphia Mint. Later still, however, from 1828 to 1845, a bona-fide platinum coinage was struck in Russia in denominations of 1, 3, 6 and 12 rubles; the coins contained some 2 per cent of iridium. The coinage value of the platinum was reckoned at about $7.15 a troy ounce, but at the present price a three-ruble piece instead of being worth $2.32 would bring about $200 of our money. Of these Russian coins 1,392,012 pieces were struck, having an aggregate weight of 473,907 troy ounces, or 14,738 kilos, and worth at the present price of the metal, nearly $32,000,000.

The honor of making the first platinum mass in Europe has been accorded to the French chemist Chabaneau, who accomplished the task in 1783 in Madrid, whither he had been called by Charles III to fill a special chair of mineralogy, physics and chemistry. This ingot weighed about 23 kilograms (some 740 ounces troy). At about this time Chabaneau made what is asserted to have been the first platinum article manufactured in Spain, a chalice which was bestowed by Charles III upon Pope Pius VI (1775–1800). The dedicatory inscription records that the chalice was made from "The first fruits of platinum rendered ductile by A. Fr.co Chavaneau." Almost contemporaneously the French chemist Achard worked the metal by alloying it with arsenic and then expelling the arsenic by heat. The method of making a compact metal out of platinum sponge by means of compression is said to have originated in 1800 with the Englishman, Thomas Cocke, although the credit has often been given to Wollaston. The modern method, by fusion before the oxyhydrogen flame, is credited to Dr. Hare of Philadelphia, who in 1837 produced in this way a homogeneous mass of platinum weighing 28 ounces (870 grams). The method was perfected by the French chemists Debray and Deville, and in the London Exhibition of 1862 the great English firm of platinum refiners, Johnson and Matthey, showed an ingot weighing 200 troy pounds, or nearly 75 kilograms. A platiniridium ingot made in Paris in 1874, in the course of the experiments to obtain proper material for the international metric standards, weighed 525 pounds. The ingot from which the standards were eventually cut was made by Johnson and Matthey. Platinum was found in the gold mines of Dakovlov, in the Urals, Russia, in 1819, in the sands of Neviansk, Bilimbayensk, in 1822, and in the Kurshinsk factories in 1824. In 1825 the rich deposits of the Nizhni-Tagilsk district were discovered. The largest platinum nugget met with in Russia came from this region; it weighed 23½ funts, or 9,628.88 grams (25 pounds, 9.45 ounces troy). Colombia, the first region where platinum was ever discovered and used, continues to furnish a notable quantity, the greatest of any land excepting Russia, though its production is normally about one-half of that of the latter land, which before the Great War supplied from 90 to 95 per cent of the entire production. The largest nugget found in Colombia weighed 800 grams; next to this comes one weighing 635 grams and containing 80 per cent of pure platinum.

Platinum is one of the most ductile of all known metals. It is so ductile that it can be drawn to the finest possible wire, then covered with a very thick coating of silver in wire form, then drawn again to infinitesimal fineness, the silver dissolved off, and this interior again coated with silver. So that one ounce of platinum wire could be made to stretch as great a distance as from New York to New Orleans, or from Buenos Aires across the Andes to the Pacific Ocean.

Although 75 per cent of the world's production of platinum comes from Canada, South Africa, and Colombia, small deposits of it have been found in many different parts of the earth. In the United States it occurs in Oregon, California, Wyoming, Washington, Nevada, Idaho, Arizona, New Mexico, Utah and Colorado, and it has occasionally been met with in other States, a fine nugget containing 38.1 grams, or almost one and one-quarter ounces troy, having been found about 1880 in glacial drift near Plattsburg, N. Y. It has also been mined in Ontario, Canada, as well as in British Columbia, and Alaska is now a large producer. In Mexico and Honduras it has also been encountered. In South America, besides the important Colombian deposits, platinum occurs in Brazil, and a little has been reported from Ecuador and French Guiana, and from San Domingo. Borneo, Burma, Assam and Ava have also furnished small quantities, and a trifle has been discovered in the Bengal Presidency and in Mysore, India. In Europe it occurs in Norway, in Finnish Lapland, in Westphalia and in the Harz Mountains, Germany, as well as in Transylvania, and a trifle has been found in County Wicklow, Ireland. Quite recently there have been discovered very promising deposits, covering a wide area, in the Ronda Mountains, province of Malaga, Spain. On the African continent platinum has been met with in Algeria, in the Kongo Free State and in Cape Colony, as well as in Griqualand. Finally, notable deposits occur in Queensland and in New South Wales, Australia, and some has been found in New Zealand and in Tasmania as well. The chief sources of platinum are alluvial deposits, wherein it usually occurs either in rounded grains, or in scales which have been worn down by the attrition of the river gravel: occasionally, however, nuggets of quite considerable size are found. It is very commonly associated with gold, and usually with one or more of the different platinum metals, iridium, palladium, ruthenium, rhodium and osmium or the alloy iridosmium. It is opaque, with a metallic lustre; the color and streak are light steel-gray, shading into silver-white. There is no recognizable cleavage; the fracture is hackly. The hardness is fully four, and the specific gravity of native, unrefined platinum ranges from 14 to 19, this wide variation being due to the percentage of iron, or of palladium, ruthenium or rhodium that may be present; the specific gravity of refined platinum is 21.48–21.50. The atomic weight is 195.21 (O = 16). The coefficient of refraction was determined by Kundt to be 1.76 for red, 1.64 for white and 1.44 for

blue, and Donde found, in reflected light, 2.06 for Na, 2.16 for red. The specific heat is 0.032 + and the coefficient of linear expansion about 0.0000049. Platinum is usually unaltered before the blowpipe, but it is readily fusible in the oxyhydrogen flame and in the electric arc, the melting point being about 1779° Centigrade, making it, after palladium, the most easily fusible of the platinum metals. It is not attacked by either boracic or phosphoric acid, nor by oxygen even when it is at a red heat, and but very slightly by pure hydrochloric acid, nitric acid or sulphuric acid. It dissolves soon, however, if treated with the mixture of nitric and hydrochloric acid, known as "aqua regia," into platinum chloride, although an admixture of iridium or even of rhodium renders it somewhat more resistant. It forms alloys with gold and a number of other metals, the resultant alloy being more fusible than pure platinum. On the other hand, it gains greatly in hardness when alloyed with iridium, the product, called platin-iridium, being applied to a number of uses where hardness is especially to be desired. Chlorine, bromine and iodine attack it, and a mixture of bromine and hydrochloric acid works as actively as a dissolvent as does aqua regia. At a high temperature platinum combines directly with sulphur, phosphorus and arsenic. Easily fusible alloys of it may be made with potassium and sodium. As there is little difference between the specific gravity of gold and platinum, the miners are not able to separate the metals by the simple method of washing in habitual use, and recourse is had to quicksilver, which by combining with the gold to the exclusion of the platinum renders it possible to extract the latter. The method of refining platinum used in the United States assay office in New York is stated by the superintendent, Hon. Verne M. Bovie, to be the following: In the electrolytic process of refining gold, platinum remains in solution in the gold chloride electrolyte, from which it is precipitated by means of ammonium chloride. The precipitate is then well washed and reduced at a red heat to a metallic platinum sponge. This naturally contains impurities, and is, therefore, redissolved in aqua regia, and evaporated almost to dryness, so as to expel the nitric acid, sulphuric dioxide being then passed through it until all the gold is precipitated. Upon this it is oxidated to bring all the platinum into a platinic state and precipitated with pure ammonium chloride. The precipitate is now reduced in the usual way to metallic platinum sponge.

Chloroplatinic acid, H_2PtCl_6, is obtained by dissolving metallic platinum in aqua regia and then evaporating the solution. If this chloroplatinic acid is stood over caustic potash for a time and the residue is heated in chlorine gas to a temperature of about 350° Centigrade, the tetrachloride of platinum ($PtCl_4$) is formed, one of the most important salts derived from the metal. The addition of sodium or potassium to the tetrachloride gives, respectively, the chloroplatinate of sodium or of potassium. The salts of platinum are usefully applied as chemical reagents and in photography.

The finely divided form of platinum, known as "platinum black," was discovered by Liebig. It possesses the striking property of absorbing and occluding oxygen in great quantity, taking up as much as 800 times its own bulk of the gas. This quality is also possessed to a marked but somewhat lesser degree by platinum sponge. Melted platinum, on cooling, emits the oxygen it has taken up with an intermittent crepitation. Ammonium platinum chloride, when heated to redness, becomes finely divided. A characteristic of the so-called "platinum-sponge," which also absorbs and condenses gases, is that when brought into contact with hydrogen or coal gas, some of the occluded gas will be emitted as a flame. Many years ago Döbereiner utilized this property for a self-lighting lamp.

In the Bureau of Standards the purity of platinum ware is now tested by a simple thermoelectric method which leaves the object that has been tested absolutely unharmed. As the thermoelectric motive force of platinum against many of its alloys has been almost exactly determined, this is used as a test of purity. In testing a crucible, for example, two wires of pure platinum only 0.1 millimeter or 0.2 millimeter in diameter, are arc-soldered to the rim and are connected with an ordinary pyrometer-galvanometer or millivoltmeter. The junction-point of one of these wires with the crucible is heated by a small oxyhydrogen flame or other blast flame, while the corresponding junction-point of the other wire is kept cool by an air blast. An interposed sheet of asbestos prevents radiated heat passing from the heated to the cool part of the crucible; the temperatures are measured by a platinum thermocouple. The significance of the result is shown by reference to a chart giving the isothermal curves for the iridium or rhodium content of platinum.

While during the Great War the use of platinum for catalyzing processes in the production of concentrated sulphuric acid for the manufacture of explosives, for dehydrating nitric acid and for aeroplane and other war machinery, was made especially prominent, the wide employment of it in electric appliances of various kinds is of at least equal importance. Large amounts of it have been used for dental work, because of its durability and its resistance to the action of acids. The latter reason has made it of the greatest possible value for various chemical vessels, such as crucibles, retorts, etc. Within the present century it has been employed by manufacturing jewelers in many ways, for watch cases and for others of the smaller ornamental pieces, and for precious stone settings, more especially for diamond settings. Because of the imperative demand for platinum in the great war industries, the War Industries Board decreed that after 1 Oct. 1918 the use of this metal in the manufacture of new stocks of jewelry or for other non-essential purposes should be prohibited. The same law applied to iridium, palladium, osmium, ruthenium, rhodium and compounds thereof. It was said that the government had a sufficient supply on hand after commandeering the stock of unmanufactured metal, and the prohibition, therefore, did not extend to platinum jewelry already made up, which could be sold as heretofore, that is, by manufacturers or dealers licensed by the War Industries Board. The decree was the result of a special emergency act to effect government control over platinum, iridium and palladium,

passed by Congress 6 Oct. 1917 and amended 1 July 1918. The situation at that time, after a careful survey, was recognized as serious. Platinum in the United States sold in 1890 at $16 per ounce troy. In 1929 the closing price on 14 Dec. was $63. During the year the price had fluctuated from a high of $110 to a low of $56, with an average of $67.66. All this has induced an active search for substitutes which might prove more or less satisfactory, and alloys of gold and palladium, or of gold and osmium, or gold and nickel, have been used with fairly good results in many cases. The shortage has also stimulated the search for platinum, not only in the metallic deposits of various parts of the United States, but throughout the entire world, and several new, minor sources have come to light.

Prior to 1900 the U. S. S. R. was the source of probably 90 per cent of the platinum metals produced in the world, most of the remainder coming from Colombia. From 1900 to 1914 the U. S. S. R. contributed about 95 per cent and Colombia the bulk of the remainder. The World War and the subsequent revolution had a depressing effect on the production of the U. S. S. R. and the output dropped to a low of about 20,000 ounces in 1921. Meanwhile, in Colombia, the government became stable, engineering methods were introduced, and production advanced rapidly. Consequently from 1915 to 1924 Colombia supplied about one-third of the world output, whereas the share of the U. S. S. R. fell to about one-half. Canada and the United States furnished the bulk of the remainder. After several years devoted to experimental refining and to the development and selection of processes for the recovery of precious metals from the nickel-copper ore of the Sudbury (Ontario) district, a refinery was built in 1924 at Acton, England, to handle annually some 30,000 ounces of platinum metals. Refining was begun there in 1925, and 16,980 ounces of platinum metals were produced there. As production of nickel and copper continued to mount, the annual capacity of the Acton refinery was enlarged to 300,000 ounces of platinum metals. In 1930 Canada recovered 68,000 ounces and became the second largest producer of platinum metals; in 1934, with an output of 200,000 ounces, it succeeded the U. S. S. R. as the world's largest producer. The Canadian output increased to 259,000 ounces in 1937 and to 292,000 ounces in 1938.

Prior to 1936 the United States had contributed only a negligible quantity to the world output of platinum metals. For example, during 1925–34 production averaged only about 8,300 ounces annually—1,000 ounces of placer platinum, 600 ounces from palladium-bearing ore, and 6,700 ounces as by-products of gold and other metals. Although important deposits of placer platinum were discovered in the Goodnews Bay district of Alaska about 1926, only a small quantity was produced through 1933. Following consolidation of claims and installation of dragline scraper equipment in 1933, the production of placer platinum in Alaska increased progressively from 3,101 ounces in 1934 to 9,823 ounces in 1937. Concurrently, by-product production from gold and other metals advanced from 2,335 to 10,578 ounces. In 1938, with a production of 49,380 ounces, the United States became the world's fourth largest producer of platinum metals.

The value of platinum, as measured by that of gold, has varied enormously in the course of years. About 1788 Colombian platinum was bought by the Spanish Royal Mint at a price equalling some 14 cents an ounce troy. At the time the Russian platinum coins were struck (from 1828 to 1845) the metal was reckoned to be worth but $7.15 an ounce troy. Fifty or 60 years later the price had increased greatly, rising from about $20 an ounce in 1906, to $45–$46 in 1911–13. With the advent of the great war, the interruption of Russian production and the increased demand for special uses caused the price to mount rapidly to $105 and even higher. In 1938 prices were: High, $43; low, $24; and the average for the year, $33.83 per ounce, compared with $76, $28, and $46.84 for 1937.

The five allied platinum metals of the platinum group, making six in all, palladium, osmium, iridium, ruthenium and rhodium, as well as the combination osmiridium (iridosmium), each have their special characteristics and usefulness.

Palladium was found in 1803 by Wollaston in crude platinum from Choco, Colombia. It was named after the planetoid Pallas. Its melting point is about 1,360° C.; its hardness, from 4 to 5; its specific gravity, 11.4. It has the lowest melting point in the platinum group. The consumption of palladium in industry in the United States is about 40,000 ounces troy, mostly in electrical work, dentistry, jewelry, etc.

Osmium has a specific gravity from 21.3 to 22.48. It was discovered in 1804 by Smithson Tennant in the residuum of South American crude platinum, after it had been treated with aqua regia. The name (from Greek *osme,* «smell») was bestowed because of the peculiar odor emitted by its volatile oxide.

Iridium was discovered by Tennant in 1804 and in the same way as osmium. Its hardness is between six and seven, that of platinum being only about four, and its specific gravity of from 22.6 to 22.8 makes it the heaviest of the platinum group. Its melting point is about 2,200° C. The name (from Iris) was chosen because of the variegated hues of its oxide.

The combination of osmium and iridium, to which the name osmiridium or iridosmium has been given, was first observed by Wollaston in 1805. Some mineralogists have used the designations iridosmium and osmiridium as signifying a lighter-hued and a darker-hued form of the alloy, respectively.

Rhodium, discovered in 1804 by Wollaston, occurs in some platinum ores. The color is a grayish-white. Its fusion point is as high as 1,940° C. While very hard, the specific gravity is low, not exceeding 12.1. Rhodium has been less used than any other of the platinum metals.

Still another metallic element found in association with platinum bears the name ruthenium. It is obtainable from the residuum resulting from the separation of osmium from osmiridium. The specific gravity is only 12.26. Ruthenium is practically unattackable by acids. It was discovered by Claus in 1845. The designation, derived from Ruthenia, an ancient name of Russia, had been applied in 1826 by Osann to one of three new metals he claimed to have found associated with platinum, another of which, his pluran, was probably the true ruthe-

nium; his ruthenium and «polin» were subsequently shown by Claus to be errors.*

GEORGE F. KUNZ.

PLATNER, Samuel Ball, American Latinist: b. Unionville, Conn., 4 Dec. 1863; d. 22 Aug. 1921. Graduated, Yale University, A.B. in 1883; Ph.D. in 1885. In 1885–90 he was instructor in Latin and French; in 1890–92 assistant professor of Latin, and after 1892 professor at Western Reserve University. In 1897–1911 Dr. Platner was secretary to the managing committee and in 1899–1900 professor in the American School of Classical Studies in Rome. In 1900–01 he was president of the American Philological Association. He edited Müller's 'Greek and Roman Versification' (1892); 'Selected Letters of the Younger Pliny' (1894) and wrote 'Topography and Monuments of Ancient Rome' (1904; 2d ed., 1911).

PLATO (Gr. *πλάπων*, «broad,» a sobriquet given by Ariston, a teacher in athletics, and referring probably to Plato's broad shoulders), was born in Athens in the deme of Collytus, in 427 B.C., of aristocratic parentage, and died there in 347. According to an ancient tradition he was born on the 7th of Thargelion, Apollo's Day, which, in Olympiad 88.1 (accepting the Metonian canon), fell on 29 May, Julian calendar. His original name was Aristocles, the name of his grandfather. His father's name was Ariston, of the line of Codrus, last of the kings of Athens, and his mother was Perictione, of the line of Solon, greatest of the Athenian archons. In many respects Solon was Plato's political exemplar, for Solon was at once philosopher and statesman. Plato distinguished himself in his early youth as an athlete, having wrestled in the Isthmian games at Corinth, and there is a doubtful tradition that he was once victor at Olympia. Before he was 20 he had written dramatic and lyric verse assiduously and with success. The most important event in his earlier life was his meeting with Socrates in 407. This event was decisive for his later career. He had already studied philosophy under the Heraclitean Cratylus, but from 407 to the death of Socrates in 399 he was entirely absorbed in the dialectic of his new master, whose chief disciple and most complete interpreter he became. Immediately after the death of Socrates in prison (Plato, owing to illness, was not present), the disciple went to Megara, where, with his friend Euclid, he studied the Eleatic philosophy. After a brief residence in Megara, it is probable that he returned to Athens, and thereafter made extensive journeys to Egypt, Cyrene in Africa, Italy and Sicily. In Cyrene he visited the mathematician Theodorus. In Italy he was befriended by the famous ruler, Pythagorean philosopher and military leader, Archytas of Tarentum. In Sicily he formed an intimate friendship with Dion, brother-in-law of the elder Dionysius. Dionysius, then ruler of Syracuse, was offended by Plato's free criticism of the government, and turned him over to the Lacedæmonian Ambassador, Pollio, to be sold as a slave. He was brought to Ægina, where Anniceris (of the Cyrenaic school) ransomed him. After his release a plot of ground hard by the academy was bought for the use of Plato's school, which then took the name of the adjoining gymnasium (academy). Plato established his academy in 387 and presided over it until his death in 347. The foundation of the academy thus dates from the exact middle of his life. Two later journeys were made to Sicily, one in 367, on the accession of Dionysius the Younger, and one in 361, both for purpose of political experiment, but without success. Indeed, on the last visit his life was put in jeopardy by the distrust of Dionysius. Thereafter he made no further attempts in practical statescraft, but carried forward continuously his scientific and literary work at the academy, where, in his early teaching, he employed a dialogic method (after the manner of his master, Socrates), and later the more dogmatic lecture. He died in 347 (according to tradition on his birthday, having thus completed exactly four score years), as Cicero says, *scribens,* «pen in hand» (*De Senectute,* v. 13). His tomb near the academy, in the Ceramicus, was still to be seen at the beginning of the Christian era.

Writings.— No work of Plato known to antiquity has been lost. On the contrary, the present *corpus* contains more than the genuine list of works. The traditional Platonic canon (that of Thrasyllus in nine tetralogies, accepted entire by Grote) contains 36 works (counting the letters as one), divided into 56 books. The works are written almost entirely (excepting the 'Apology') in dialogue, a form which grew out of the Socratic conversations, which these writings purport to reproduce. They are not systematic treatises, but rather essays, the earlier of which are more peirastic and the later more dogmatic (cf. Pater's 'Plato and Platonism,' pp. 157–159). Their chronology represents the gradual philosophical evolution of Plato's own mind, and not any preconceived pedagogical plan. Regarding the determination of the sequence or dates of the dialogues, no consensus of opinion among Platonic scholars has been

* Hintze, 'Handbuch der Mineralogie' (Leipzig 1904, p. 141); Consult G. Osann, 'Untersuchung der russischen Platina' (Ann. der Phys. Pogg. Vol. VIII, 1826, p. 505), and C. Claus, 'Untersuchung des Platinrückstandes, nebst vorläufiger Ankundigung eines neuen Metalles (Ruthenium)' (Bull. Acad Sci. St. Petersburg, Vol. III, 1845, pp. 38, 311, 354).

eached. The most important dialogues are the 'Symposium' (on Love), the 'Phædo' (on the Immortality of the Soul), the 'Republic' (on the Ideal State), the 'Theætetus' (on the Nature of Knowledge), and the 'Timæus' (on the Nature of the Physical World). Three periods of composition may be differentiated, namely: (1) A Socratic or Ethical period, in which the anti-sophistic dialogues were written. This period may be regarded as extending from 398 to 387, that is, from the beginning of Plato's philosophical writing to the opening of the academy; (2) a Metaphysical and Constructive period, in which Plato builds the Socratic concept into its metaphysical form, develops the theory of ideas, invents his great myths, constructs the ideal state, and reaches the climax of his intellectual and literary genius — a period extending from 387 to 360; (3) a third period, marked by increasing mysticism and decreasing literary and philosophic power, a growing ascendency of Pythagoreanism and mathematical symbolism, a less daring civic ideal, a more dogmatic and less versatile manner of utterance and a greater emergence of religious interest — a period extending from the last Sicilian journey, or about 360, to his death in 347. See Plato's Republic; Symposium; Platonism.

I. *The Socratic and Anti-Sophistic Group,* 398–387: (1) 'Apology': (2) 'Euthyphro'; (3) 'Crito'; (4) 'Lysis'; (5) 'Charmides'; (6) 'Hippias II'; (7) 'Laches'; (8) 'Protagoras'; (9) 'Meno'; (10) 'Euthydemus'; (11) 'Gorgias'; (12) 'Republic,' Books I and II; or, in the pagination of Stephanus, from 327 to 368 A.

II. *The Metaphysical and Constructive Group,* 387–360: (13) 'Cratylus; (14) 'Symposium'; (15) 'Phædo'; (16) 'Republic,' Book II, 368 A to Book V (inclusive), and Books VIII–X; (17) 'Phædrus'; (18) 'Theætetus'; (19) 'Parmenides'; (20) 'Republic,' Books VI–VII, and reconstruction and unification of the entire work, Books I–X; (21) 'Sophist'; (22) 'Politicus'; (23) 'Philebus.'

III. *The Physico-mathematical and Politico-religious Group,* 360–347: (24) 'Timæus'; (25) 'Critias'; (26) 'Laws.'

The following are spurious: 'Alcibiades I and II,' 'Hipparchus,' 'Clitophon,' 'Theages,' 'Minos,' 'Epinomis,' 'Axiochus.' 'Letters,' 'Hippias I,' 'Amatores,' 'Definitiones,' 'Ion,' 'Demodocus,' 'Eryxias,' 'De Justo,' 'De Virtute,' 'Timæus Locrus,' 'Menexenus.'

PLATOFF, plä'tōf, or **PLATOW, Matvei Ivanovitch,** Count, Russian general and hetman of the Cossacks: b. on banks of Don River, Russia, 17 Aug. 1751; d. Tcherkask, Russia, February 1818. He entered young into the military service, was employed against the Turks in Moldavia, and was made a general of cavalry. When the French invaded Russia in 1812 Platoff was again called into service, and though defeated at Grodno and obliged to retire into the interior, returned during the retreat of the enemy from Moscow, and with 20 regiments of Cossacks harassed them in their flight, and contributed greatly to the advantages gained over them. In 1813 he defeated Lefebvre at Altenburg, and after the defeat of the French at Leipzig entered France, and was at Paris with the Emperor Alexander, whom he accompanied to England. At London he was the object of popular admiration, and a magnificent sabre was presented to him. In 1815 he commanded the Cossacks destined for the second invasion of France, and again made his appearance at Paris. After the restoration of peace he retired to Tcherkask.

PLATONIC YEAR, the name given the period of time which the equinoxes take to finish their revolution, at the end of which the stars and constellations have the same place with regard to the equinoxes that they had at first. Tycho Brahe says this year or period requires 25,816 common years to complete it; Ricciolus computes it at 25,920; and Cassini at 24,800; at the end of which time some imagined that there would be a total and natural renovation of the whole creation.

PLATONISM, the system of philosophy taught by Plato. The tripartite division of philosophy into Dialectic (Metaphysics), Physics and Ethics is not explicitly made by Plato, although these several disciplines are discussed in the various dialogues and the classification is implicitly made.

Platonic Metaphysics.— The fundamental discipline in the Platonic philosophy is the Metaphysics, and the central doctrine in this discipline is the doctrine of ideas. The basic elements of the doctrine are derived from preceding philosophies, although they are here reconstructed with creative genius into a new system. The Platonic ontology is an attempt to mediate between the metaphysical antithesis of Heracliteanism (the philosophy of becoming or "flux,"

with the denial of all Being) and Eleaticism (the philosophy of static Being, with the assertion that all Becoming is illusory). The mediation was effected by means of the Socratic concept. Socrates did not carry his theory of the concept beyond its ethical implications; Plato in applying it to the resolution of the Eleatic and Heraclitean antimonies constructed a theory of reality. The Socratic concept is a general notion or universal idea in contradistinction to a sensation or perception, which is particular. The former is the content of rational thought or scientific knowledge; the latter is the content of sense experience; the former has universal validity and is stable; the latter is individual and variable. Plato correlated the concept, as the universally valid idea, with Being or the permanent; perception or sensation he correlated with the individual, that is, with the transient or Becoming. The one is the world of thought or ideas; the other is the world of perception or phenomena. The one is the world of reality; the other the world of appearance. The doctrine of ideas is thus made to overthrow the Protagorean doctrine of the relativity of knowledge. General notions or ideas, in Plato's next step, are hypostasized, that is, they are erected into self-existant, transcendent entities, spaceless and timeless. The Platonic idea is an archetypal form or notional entity, in which all particular things participate, in so far as they bear the name of the archetype as a class name. For example, in so far as the names man, justice, wisdom are applied to Socrates. the individual Socrates participates (*μέθεψις*), in these generic notions, or these ideas of justice, etc., are present (*παρουσία*) in him, or he is patterned (*παράδειγμα*) after them. The archetype is the genus; the individual is a particular subsumed under it. The archetype or generic idea is, therefore, the principle of classification of particulars into groups, which groups exhibit the ideal or essential reality of particulars. Intelligible and sensible realities represent the One and the Many, and these logical relationships are interpreted by Plato ontologically. The relation of the universal to the particular is in certain dialogues described as that of archetype or pattern, in others as participation, indwelling or communion. Further, these ideas are conceived as efficient causes or energies which give life, growth and significance to the world of phenomena, and they are furthermore final causes in terms of which the world's processes are regarded as purposive. Looked at ontologically the Platonic idea is the essentially real, absolute Being; looked at epistemologically, it is the absolutely knowable, the object of rational thought; looked at ethically and æsthetically, it is the norm. The supreme idea is the Idea of the Good, whose position and function in the world of ideas is analogous to that of the sun in the world of phenomena. The ethical and teleological character of the Platonic metaphysics is given in the supremacy of this concept, which is identical with God. This supreme idea is the rational conception of the total cosmic good, exhibited completely in the character of the Absolute, and imperfectly expressed in the laws of nature and in the government and conduct of men.

Platonic Physics.— Nature is a sphere that undergoes constant transformation. It is not a world of Being (*τὸ ὄν*, "being," connotes fixity and stability), for it does not persist and is not invariable; it is not non-being, for it is the object of sense-experience; it is a world midway between Being and non-Being, that is, a world of Becoming, in constant transit from non-being to being. The idea appears in the phenomenal world veiled in matter and confusedly expressed. Matter is the principal of multiplicity and variability and is one of the vaguest notions in Platonism (as it is in all philosophy). In the "Timæus" (48 B *seq.*) Plato appears to identify it with space — the receptacle of ideas out of which (or more strictly, into which) the Demiurge fashioned or configured the extended and visible world. The world is not eternal, but is created. Space or matter is eternal, but time comes into being with the world's creation. The efficiency of the ideas in reference to nature is personified in the mythical Demiurge. He is the cosmic energy of the ideal world of reason and goodness, and the created world is, therefore, reasonable and good. A world-soul is created by the Demiurge, that is, the world is made a living organic whole, self-moving, its motions mathematically determinate, developing in itself and in individuals consciousness, and teleologically imaging the ideal world. The goodness of the supreme idea is the ultimate cause of the world.

Platonic Psychology.—In the Platonic dualism of ideal and phenomenal, the individual soul occupies a mediate position, that is, it is so constituted as to be related to the ideas on the one hand and to the sensible world on the other. By reason the soul apprehends and is cognate with the first; by sensation it apprehends and is cognate with the second. Reason is the function of the immaterial soul, while sensation is bound up with the material body, in which the soul lives as in a prison. The soul is older than the body and existed prior to its union with the body. The doctrine of preexistence is joined to the doctrine of the immortality of the soul. The three so-called parts or faculties of the soul are reason (*νοῦς*), the spirited element (*θυμοειδές*), and the appetitive element (*ἐπιθυμητικόν*). The seat and organ of the first is the head (the Acropolis of the body, 'Tim.' 79 A); of the second the thorax, particularly the heart; of the third, the organs below the diaphragm. According to the 'Phædrus' these three parts form a unitary soul and are immortal; according to the 'Timæus' they are separable and only the reason is immortal, while the inferior parts perish with the body. The platonic arguments for the immortality of the soul are (consult 'Phædrus,' 'Phædo,' 'Republic'): 1. The soul is a self-moving principle; its motion, consequently its life, is, therefore, perpetual. 2. The peculiar disease or evil of the soul is vice; if the disease peculiar to a thing does not destroy it, it is indestructible. Vice does not destroy (it corrupts) the soul, therefore it is indestructible. 3. The cyclical argument, namely, the cosmic law of the passage of opposites over into each other, for example, night, day; heat, cold; winter, summer; sleeping, walking; decaying seed, living plant; so death, life. 4. The doctrine of reminiscence shows the learning of mathematical and philosophical truths is only the application of ideas, principles or axioms already in the mind and this implies a pre-existent state.

5. The soul, as an immaterial entity, is essentially related to the immaterial, invisible ideas and these are eternal. 6. The idea of life is inseparable from the idea of soul (the Greek word ψυχή means "principle of life" as well as "soul"). 7. The soul is indiscerptible. That which is indiscerptible cannot be disintegrated. 8. The superior dignity and worth of the soul argue for its survival of the body. 9. The instinctive aspiration toward and longing for a future life shows that the doctine of immortality is founded in the soul's nature. 10. The world as a moral, just world demands a future existence for the rectification of the inequalities in this life.

Platonic Ethics and Politics.— Plato founds his theory of virtue on a psychological basis. The parts of the soul are regarded as having distinct and separate functions; the right performance of these several functions produces an organic well-being or moral health. The virtue peculiar to reason is wisdom; to the spirited element, courage; and to the appetitive element, moderation. A fourth cardinal virtue is justice, which is the harmonious condition of the entire soul resulting from the performance of its own function by each "part" and its non-interference with the functions of other parts. Piety, sometimes enumerated as a fifth virtue, is the aspect of justice which consists in the performance of what is due to the gods. It is the function of reason to furnish true principles of conduct to the individual; of the spirited element, to be courageous, ready and eager in the execution of the principles of reason — principles which become commands for the lower faculties, and of the appetitive element to desire only that which reason prescribes as moderate. Thus in referring the content of virtue to reason, Plato puts in terms of his psychology the doctrine of Socrates that virtue is knowledge. The Socratic-Platonic conception of virtue is very similar to our "acting on principle." It is the "principle" that gives moral value to conduct and the reference of morality to knowledge (Socrates) or to reason (Plato) has essentially this meaning. The *Summum Bonum*, as described in the late dialogue, is to become, as far as man can, like God (ὁμοίωσιστῳ θεῷ), the Absolute Good. The state, in Plato's description, is the individual "writ large." Corresponding with the three elements of the soul he distinguishes three civic classes: the legislators, the warriors and the tradesmen (including all the lower classes). The state, therefore, is wise, courageous, temperate and just (in a way analogous to the individual citizen) in that degree in which these several classes perform their functions duly. Plato conceives the aim of the state, as of the individual, to be moral perfection, not power. His ideal government is an intellectual aristocracy, in which only the best endowed and intellectually best trained citizens shall be elevated to the office of legislators. Men scientifically trained, after submitting to a long propædeutic in the actual business of government in its lower branches, shall gradually come to the exercise of the highest civil functions. The preliminary education of this class (which is entirely under state control) is of the utmost importance and is described, both in its spiritual and physical branches, with great detail. Among the most striking features of the ideal state is its communistic character, a communism that extends not only to property, but to wives and children. The communism does not, however, apply to the citizens as a whole, but only to the two upper classes, whose lives are spent in the service of culture and the government. Plato insisted that the highest good of the individual is secured in the highest good of the state, and so the former is apparently merged in the latter. Finally, the Platonic communism is not aimed so much at securing equality of property, as at the exemption of the highest citizens from the distractions of the sense-world and at securing complete devotion to the pursuit of philosophic truth.

WILLIAM A. HAMMOND,
Professor Emeritus of Ancient and Mediæval Philosophy, Cornell University.

PLATOON, a French military term formerly used to designate a body of troops usually half a company, who fired together. It is still used in the expression *platoon exercise*, which includes the manœuvres connected with the handling and using of the rifle.

PLATO'S REPUBLIC. The title of Plato's 'Republic' might seem to indicate that the main purpose of the dialogue was economical and sociological; but so to understand it is to run the risk of emphasizing what is eccentric in the author's thought, while missing what is essential and permanently human. The central theme of the argument is avowed clearly in the opening paragraphs of the second book (restated at other turning points), and is conditioned by the conclusions of the "Protagoras" and "Gorgias" and other dialogues which, probably precede 'The Republic' in order of composition. In these earlier works Plato had been concerned principally with two questions, which to him as a true Socratic, and indeed to any thoughtful Greek of his age, were really one: What is the nature of virtue? and, In what does man's happiness consist? In the "Protagoras" it was suggested that virtue is that kind of action which in its ultimate consequences produces pleasure, and that happiness is the largest possible balance of pleasure over pain. This was the calculating

hedonism (from *hêdonê*, pleasure) which, apparently, Plato learned from Socrates. It was not in itself a base form of ethics, since under "pleasure" might be embraced the finer emotions of honor and sympathy; but it was likely to leave its votary in the lurch just when he most needed help, and at the best it was, and is, a treacherous guide. In the obscure complexities of life it is wont to bid the doubting soul "take the cash and let the credit go." Plato felt this, and in the "Gorgias" he started the search for quite another rule. Here pleasure is portrayed as the temptress who lures men to destruction by the urgency of momentary satisfaction. In contrast with the current ethical theory, which based itself on the so-called law of nature and defined justice as the right of the stronger to grasp whatever pleasures are available, he sets up the law of absolute justice. Only one thing I know, he says, speaking through the mouth of Socrates (being true in this to his master, though the law may seem at variance with the other Socratic law of hedonism), "that it is better to be just than to be unjust, better, if need be, to suffer the extreme of injustice than to do injustice — better because so one is happier." Happiness is thus no longer identified with pleasure, or with the sum of pleasures, but is a feeling different in kind and more momentous in character. From it is derived the ethics of eudemonism (from *eudaimonia*, happiness), which henceforth Plato will advocate in place of hedonism. In the first book of 'The Republic,' after a marvellously beautiful *mise en scène*, the argument of the "Gorgias" is virtually summed up in a refutation of the Nietzschean doctrine of might and right. Then, in the opening of the second book, the problem in its new form is stated in the most forcible terms. On the one side Socrates and his friends draw a portrait of the man who is altogether unjust and by his injustice wins for himself all the pleasures of this world. Furthermore, they will suppose that by some device, such as the invisible ring of Gyges, he shall be able to escape detection and to acquire the reputation and honors of justice; even the gods shall be bought off, so that he is under no fear of punishment in the future world. On the other side they set up the man who is just in every action, yet suffers all the misfortunes of life, including the ignominies of seeming injustice. Which of these two men, they ask, will be the happier? Their answer, without hesitation, is that the good man, without any of the pleasures of life, will be happier than the bad man, with all the pleasures of life. This they admit, is a paradox, and needs to be examined. First of all what is this quality of justice whose consequences are so extraordinary? To answer this query Socrates suggests that, as the state is only a man writ large, it may be easier to discover the virtue they are seeking in the composition of society than in the individual soul. Now the principle of civilization is the division of labor, and this, to be effective, must be carried into the very constitution of the state. There are three main functions of society — production, defence and government. Hence there will be three classes of citizens — the producers, the fighters and the governors. And each class will have its specific virtue — temperance, regarded chiefly as obedience, in the producers, courage in the fighters and wisdom in the governors. The fourth virtue, justice, will be the effective principle of organization which keeps each class in its place and binds the whole together into one body politic. As a precaution against the temptation to greed and tyranny, the two higher classes are deprived of all property beyond a few personal necessities; even their wives are to be in common, and women are to partake, so far as their weaker nature permits, in all the employments of men. And the wisdom of the governors is to rise into that pure region of philosophy wherein the ordinary interests of the world are lost in the contemplation of eternal ideas. An echo of this belief in the efficacy of philosophy may still be heard in the words of John Stuart Mill: "The moral and intellectual ascendancy, once exercised by priests, must in time pass into the hands of philosophers, and will naturally do so when they become sufficiently unanimous, and in other respects worthy to possess it" — but the unanimity between Platonism and utilitarianism is still to seek. Plato's state may be described as an aristocratic communism. In criticizing it two things must be remembered: First, it was developed by Plato as an ideal, "a model laid up in heaven," rather than as a practicable scheme; secondly, its avowed purpose was not so much sociological as psychological, to throw light on the composition of the individual soul. Unfortunately Plato does not always keep this purpose before the eyes of the reader, nor does he himself always see the limits of the analogy he is proposing. The errors of his statecraft spring from his failure at times to distinguish between a society which is composed of units each with a will of its own, and an individual soul whose faculties are merely the various aspects of one will. Corresponding to the three classes of society he finds in the soul three faculties — the appetitive, the *thymoeides* (an untranslatable term, signifying in general the emotions of anger, indignation, pride, self-respect, as distinguished from the physical desires of the appetitive faculty), and reason. The specific virtues of temperance, courage and wisdom belong to the faculties respectively, as they perform their special functions. Justice, then, would be that general principle of morality which instigates each faculty to its right exercise, and binds them together in harmonious activity. Justice is to the soul what health is to the body. If this analogy is sound it should seem to follow without further words that the just man is the happy man. But to distinguish more clearly the nature of happiness itself, and to bring conviction to the doubter, Plato adds a series of portraits of the just character and of the characters that gradually fall away from justice, combined with an account of the state as it declines from a true aristocracy (that is, the rule of the best) to democracy (meaning by this mere mob rule). Looking on these extremes, he asks, can any one doubt which is the happy man and the happy state? So he solves the problem proposed at the beginning of the discussion. But by the way he has touched on almost every aspect of human life, — education, literature, music, science, religion, all are considered in connection with his central theme, and all are illuminated.

PAUL E. MORE.

PLATOON, one of the subdivisions into which a company of infantry may be divided. A regular platoon in battle consists of two to four squads of eight men each, and may be assigned to lieutenants and non-commissioned officers in order of rank. Formerly, in the 1600's, platoons were commanded by captains, and were often used to lead infantry tactics. During the following century they were organized into battalions; and in the 19th century, the term was applied to recruit squads undergoing military training. In Great Britain, the present platoon division of a company of infantry was introduced into the regular army formation in 1913, prior to the World War. In the United States, a group of four platoons constitute a troop of cavalry, or a battery of artillery. The term was originally used to designate a body of troops who fired together.

PLATOV, Matvei Ivanovitch. See PLATOFF, MATVEI IVANOVITCH.

PLATT, Charles Adams, American architect and painter: b. New York, 16 Oct. 1861; d. 12 Sept. 1933. His art education was acquired in New York and Paris, in which latter city he studied under Boulanger. In 1894 he gained the Webb prize of the Society of American Artists for his painting 'Clouds'; and in 1900 his 'Snow' was awarded a bronze medal at the Paris Exposition. He was a National Academician, a Fellow of the American Institute of Architects and in 1912 received the Medal of Honor of the New York Chapter of the Institute. He is the author of 'Italian Gardens' (1892). See "Monograph" by Royal Cortissoz.

PLATT, Orville Hitchcock, American legislator: b. Washington, Conn., 19 July 1827; d. there, 21 April 1905. He studied law, was admitted to the bar in 1849 and established a law practice at Meriden, Conn. In 1857 he was a clerk in the State senate, served as a member of the body in 1861–62, was elected to the Connecticut house of representatives in 1864 and 1869, serving as speaker during the last year, and from 1879 until his death was a member of the United States Senate. As member of the Committee on Relations with Cuba he introduced the amendment which placed Cuba under the military protection of the United States.

PLATT, Thomas Collier, American politician: b. Owego, Tioga County, 15 July 1833; d. New York, 6 March 1910. He entered Yale in 1849, but ill health obliged him to give up his college course. He then entered business as a merchant in Owego, and became president of the Tioga National Bank when it was organized in 1865. He also had large number of interests in Michigan. He later (1879) became secretary and manager of the United States Express Company and in 1880 its president. His first political position was that of clerk of Tioga County, 1859–61, and here he supported the political interests of Roscoe Conkling; gradually gaining control of the Republican organization of the district, he was elected to Congress in 1872 and 1874. In January 1881 he was elected to the United States Senate, and in May of that year resigned with his colleague, Roscoe Conkling, because of President Garfield's disregard of «senatorial courtesy» in appointing the collector of the port of New York without consulting them. They both sought re-election by the New York legislature, but Platt withdrew from the contest before it was decided. He had in 1880 been appointed a member of the board of quarantine commissioners of New York City, and from 1884 to 1888 was president of the board. He took no openly active part in politics until 1884, when he was delegate to the National Convention. From that time, however, he slowly and unobtrusively gained control of the Republican party of New York State, until he became its acknowledged leader. For years he dominated Republican politics, apparently because he liked power, for he displayed no desire for wealth or personal preferment. He was widely known as the «easy boss.» In 1896 he was elected United States senator and re-elected in 1902 for a term of six years. He attended every Republican national convention from 1874 to 1900; in 1896 was influential in obtaining an unqualified declaration for the gold standard; and in 1900 gained the nomination of Roosevelt for Vice-President. His power in his own State was due largely to his knowledge of every detail of the political situation and to his skill in dealing with men personally. James G. Blaine said of him «He has strong common sense and a quick judgment of men.»

PLATT NATIONAL PARK, a tract with a total area of 848.22 acres, set aside for park purposes by the acts of Congress of 1 July 1902 and 21 April 1904 (629.33 and 218.98 acres respectively by each act) at the town of Sulphur, Okla. (then Indian Territory). It was at first designated as the Sulphur Springs Reservation, which, by joint resolution approved 29 June 1906, was changed to Platt National Park. The park extends in irregular form a distance of approximately three miles from northeast to southwest along Travertine Creek, including a portion of Rock Creek, into which the Travertine empties, and it has a circuit of nine miles. Within the park are a number of known mineral and three non-mineral springs. The principal groups of springs are the Bromide and Medicine springs in the extreme western portion of the park; the Beach, Pavilion and Hillside springs in the north central portion, and the Bromide-Sulphur, Black Sulphur and Wilson springs in the south central part. Sulphur springs predominate. Travertine Creek is fed by the Antelope and Buffalo springs, both non-mineral. About 30,000 individuals visit the park annually. About 50,000 gallons of the bromide and medicine water are bottled and shipped annually to distant points. Consult 'Report to the Secretary of the Interior by the Superintendent of the Platt National Park' (Washington, D. C., annually).

PLATTDEUTSCH, plät'doich, **NIEDERDEUTSCH,** or **LOW GERMAN,** the language of the lowlands of northern Germany, spoken from the borders of Holland to those of Russian Poland; its southern limit follows a line drawn from Aachen through Bonn, Cassel, Quedlinburg, Dessau, Wittenberg, Meseritz and Thorn; its northern boundary reaches the Danish frontier. It belongs to the same linguistic group as the Dutch, the Flemish and the Friesian, and it is nearer to English than is the High German. Low German, before the time of the Reformation, was the language of literature as well as of common life within the

geographical limits mentioned; the Bible was translated into Plattdeutsch before any version into High German was made; but Luther's Bible having been composed in High German and circulated as no book ever before — one bookseller in Wittenberg sold in 40 years 100,000 copies, and before 1559 it was reprinted in 38 editions — the High German dialect was recognized thenceforth as the superior literary medium. The Plattdeutsch accordingly went into decline, the issues from the press in that dialect growing gradually fewer till, in the end of the 17th century, its literary use had practically ceased. But in recent times there has been a revival of Plattdeutsch literature, and the several Low German dialects have received a good deal of attention from linguistic scholars. The oldest extant literary monument of the Low German language is the 'Hêliand' (healer or savior), a history of the life of Christ composed in alliterative verse; it was written about the year 830 by a Saxon cleric or monk.

PLATTE, plăt, a river which rises in the Rocky Mountains, formed by the junction of two streams called the North and South Forks of the Platte. The total drainage area is over 100,000 square miles. The North Platte is formed by the union of several streams in the North Park, Colorado, and the South Platte takes its rise in the South Park. They flow north and east, uniting in Lincoln County Neb., about 400 miles from their source. The united stream, flowing mostly east, crosses Nebraska and enters the Missouri 15 miles south of Omaha, after a course of about 1,600 miles. The principal affluents are the Elkhorn and the Loup Fork. The river is from one to three miles wide, but so shallow that it is not navigable. The two Plattes are extensively used for irrigation purposes, and as a source of water power.

PLATTE COUNTRY, THE, in American history, a name applied prior to 1854, given to the territory stretching west from Missouri to the Rocky Mountains, and which now comprises the States of Kansas and Nebraska. A bill was introduced into Congress in 1854 by Douglas of Illinois for the organization of the territory, the slavery question to be determined by the inhabitants, in direct violation of the Missouri Compromise.

PLATTENSEE, plät'tĕn-zā. See BALATON.

PLATTER, plät'tėr, **Thomas,** Swiss scholar and humanist educator: b. Grenchen, near Visp, in 1499; d. Bâle, 1582. In his boyhood he was a goat-herder in the mountains, but later his mother sent him to the local priest for instruction. He soon outgrew the narrow limits of the education obtainable from this source and became a wandering scholar. In company with a cousin he wandered throughout Germany, leading the wretched life of bacchants, but this became distasteful and he separated from his companion and entered the school at Schlestadt under Jean Sapidus to study Latin. Some time later he went to Zürich to study under Myconius, and while there learned the trade of rope-making, which enabled him to continue his studies of Greek and Hebrew. In 1541 he became professor of Greek in the gymnasium at Bâle and continued in that capacity until 1578. Platter's most important work was his autobiography, written at the request of his son Felix (1536–1614). The document gives an interesting history of education in the 16th century and shows the life of the students and scholars of that time, besides telling of his own travels. It was published in the original in 1840 and later the biographies of the father and son were edited together by Heman (Gütersloh 1882).

PLATTEVILLE, Wis., city in Grant County; alt. 918 feet; 88m. SW. of Madison; on the Chicago and North Western and the Milwaukee railroads. It is in the center of the former lead and zinc mining section of southwestern Wisconsin. Lead mining in Wisconsin reached its peak by 1850; zinc refining flourished during and after the Civil War. Both declined but have had occasional spurts of renewed activity, as in the war years, 1914–19. Platteville is the seat of a state teachers' college. The city was founded in 1827. Pop. (1940) 4,762.

PLATTNER, plat'nėr, **Karl Friedrich,** German chemist and metallurgist: b. Kleinwaltersdorf, near Freiberg, Saxony, 2 Jan. 1800; d. Freiberg, 22 Jan. 1858. Very little is known of his early life until 1842, when he became professor of metallurgy at Freiberg, a post he held there until 1857. During this time he experimented with marked success, but he became noted mostly through his application of the blow-pipe to the quantitative assay of metals. He published 'Probirkunst mit dem Löthrohr' (1835), etc.

PLATTSBURG, N. Y., city and Clinton County seat; alt. 140 feet; on the west shore of Lake Champlain, at the mouth of the Saranac River; 167m. N. of Albany; on the Delaware and Hudson Railroad; has steamboat connection with Burlington, Vt., and other cities on the lake. Its principal industry is the making of wood pulp and paper; razor blades and concrete blocks are additional products. It has good schools, and is the seat of a state normal school, which was opened in 1889 and burned down in 1929; the old buildings were replaced by a modern stone structure. Three miles distant is Cliff Haven, seat of the Catholic Summer School of America, where summer courses are given by Fordham University (q.v.) and boys are trained for leadership. A few miles west of Plattsburg is the Adirondack State Park, with 5½ million acres, of which more than two million are required by state law to be held forever as wild forest land. Down the lakes, almost opposite Burlington, Vt., is Ausable Chasm (q.v.). Plattsburg has an interesting history, and some of its high points are commemorated in the Champlain Monument, honoring the discoverer of the lake (see CHAMPLAIN, SAMUEL DE), and the Macdonough Memorial, dedicated to the commander of the American fleet on the lake in the War of 1812. The memorial is a shaft 135 feet high, with the names of Macdonough's ships inscribed on the base: the *Saratoga,* the *Ticonderoga,* the *Preble,* and the *Eagle.* Plattsburg was settled in the last decade of the 1700's by Zephaniah Platt, his three brothers, and others from Poughkeepsie and Long Island. Zephaniah had been a colonel of militia in the Revolution, and the place was named in his honor. Early in the Revolutionary War (11 Oct.

1776) a naval battle was fought off Valcour Island, five miles from Plattsburg. The Americans under Benedict Arnold had 16 small ships. Intercepting the British ships on their way south, to open a campaign for control of the waterways and to cut New England off from New York, the American ships fought hard all day, and then in the night slipped away and sailed down the lake. The battle had blocked the British move for control of Lake Champlain. The second naval battle on the lake took place on 11 Sept. 1814; it was the last naval battle between two English-speaking peoples. British troops set for a land attack on Plattsburg waited for British ships to drive off Macdonough's fleet. Macdonough, however, won the naval victory, and General Macomb's forces were victorious on the land. A few months after this battle a military reservation was established at Plattsburg. In the First World War it was used as an officers' training camp, and in peace years citizens' training camps have been held here. Pop. (1930) 13,349; (1940) 16,351.

PLATTSBURG, Battle of. See CHAMPLAIN, LAKE OF, IN WAR OF 1812.

PLATTSBURG BARRACKS, a military post established by the United States in 1838 on the west shore of Lake Champlain just south of the city of Plattsburg, N. Y., on the Delaware and Hudson Railroad. It has the usual equipment of a military post. Here, in 1916, was established the first citizens' military training camp in the country, which, during the World War, was used for training officers. Since the war numerous graduates of the training camp have received commissions in the Officers' Reserve Corps, U. S. Army.

PLATTSMOUTH, Nebr., city and Cass County seat; alt. 968 feet; on the Missouri River, at the mouth of the Platte River; 19m. S. of Omaha; on the Burlington, and the Missouri Pacific railroads. The surrounding area is predominantly agricultural; the city is industrial, producing baskets, brooms, and canned foods. It has flour mills. There is an establishment for construction and repair of refrigerator railroad cars. There are extensive deposits of stone, sands and clays in the vicinity, and their exploitation is important in the city's schedule of industrial activity. Plattsmouth has a good public school system, a public library, and a courthouse. The King Korn Karnival is held each year in the fall. Besides the showing of farm products, there is a varied program of entertainment. Formerly a representative «river town,» when the Burlington Railroad came through and established shops, the city changed its ways accordingly. Early traders frequented this locality; the city was platted in 1854, and incorporated in 1855. Pop. (1930) 3,793; (1940) 4,258.

PLATYHELMINTHES, a phylum of the Metazoa, commonly known as the flatworms, characterized by a bilaterally symmetrical body, somewhat flattened dorsoventrally and usually elongated. The primary body cavity is filled with parenchymatous tissue, giving characteristic firmness to the body. The alimentary system is sacculate and provided with but a single opening, and the excretory organs are of the simple protonephridial type. On the other hand the reproductive organs are unusually complex, and in all save a few species hermaphroditic. The phylum is well defined, containing three great classes, the Turbellaria or free-living flatworms, the Trematoda or flukes, and the Cestoda or tapeworms. Of the few aberrant or little known groups formerly associated with this phylum only the Nemertinea are still placed here; they are given independent rank, and usually treated as an appendix though often omitted entirely from the phylum. The body is covered in the Turbellaria by a simple ciliated epithelium, and in the Trematoda and Cestoda by a so-called cuticula which has not been clearly interpreted as yet since the epithelial cells are apparently wanting though glandular cells sunk deep in the parenchyma are often interpreted as epithelial in origin. Directly beneath the epithelium or the cuticula one finds a well developed dermo-muscular sac in which longitudinal and transverse layers are always seen and often a third layer made up of oblique bundles. Dorsoventral muscles extend through the parenchyma from surface to surface and special muscles are also found in connection with organs like the suckers, spines, etc. There is no skeleton and the only hard parts present are hooks and spines that develop on the surface of the body or of some invagination of the external layer.

Special circulatory and respiratory organs are entirely lacking, but the excretory system is well developed. It consists of so-called «flame cells», i.e., ciliated cells, that close the inner ends of minute tubules; these form a branching system that leads to one, two, or more external pores. Just within the pore one finds often a storage bladder formed by an expansion of the tubule. Asexual reproduction by division is common in the Turbellaria and metagenesis or alternation of generations occurs in Trematoda and some Cestoda. Although nearly all Platyhelminthes are hermaphroditic a single germ gland produces only one kind of sex cells and the complex reproductive system, which forms the conspicuous part of the body in the sexually mature individual, comprises a complete set of male and of female organs. Development is simple in the free living Turbellaria and often very greatly involved in the parasitic Trematoda and Cestoda where alternation of hosts is the rule and even three or four hosts participate in the life history of a given species. Many efforts have been made to trace relationship between the Platyhelminthes and the Cœlenterata on the one hand and the higher worms or simplest mollusks on the other. While one recognizes in general the intermediate character of the flatworms, it has not yet been feasible to trace more definite connections in either direction. The process of change within the phylum is distinctly traceable from the free living Turbellaria with ciliated epithelium and special sense organs that show adaption to independent existence through the ectoparasitic and endoparasitic Trematoda to the Cestoda. In the latter the consistent endoparasitic habit is correlated with entire disappearance of the alimentary canal as well as with the loss of ciliary locomotor apparatus and special sense organs. Consult Lankester, 'Zoology' (London 1901) and Her-

turg-Kingsley, 'Manuel of Zoology' (New York 1912).

PLATYPUS, a genus of monotremes, called *ornithoryncus,* peculiar to New Holland, seemingly a link between the aquatic bird and the mammalia. It is about 12 inches in length, covered with a thick, soft fur, dark brown above, and whitish beneath. The muzzle is elongated, enlarged, flattened; the teeth are situate in the back part of the mouth, two on each side; the feet are webbed, and the hind legs are armed with spurs which secrete a poisonous fluid; the tail is flat and obtuse; there is no external ear and the eyes are very small. The echidna or spinous ant-eater is a genus resembling the platypus, but not amphibious. See DUCKBILL.

PLAUEN, plou'ĕn, Saxony, town situated on the White Elster, 20 miles south by west of Zurickau. It contains an old castle, Rathaus, theatre, gymnasium, Realschule, teachers' training school, etc. It is one of the most important cotton-manufacturing centres of the country, turning out great quantities of cambric, lace, muslin, batiste, embroidered goods, etc. Other industries produce pianos, paper, safes, machinery, etc. Pop. 111,398.

PLAUTUS, the third of the Roman dramatists in chronological order and the first in literary and linguistic importance. His full name was Titus Maccius Plautus; it was formerly supposed to be M. Accius Plautus and is so given in editions before 1850. He was born in Sarsina, a small Umbrian town, about 254 B.C., probably of free parents, but in humble station. Of the events of his life only three are known definitely: the 'Stichus' was written by him for the plebian games in 200 B.C.; the 'Pseudolus' was given at the dedication of the temple of the Magna Mater in 191; he died in 184. There is a brief notice of his literary activity in Gellius, iii, 3, 14, in which it is stated that after coming to Rome he was engaged in some work connected with the stage, that he used the money thus earned in trading by sea and having lost it, he returned to Rome in such straits that he was obliged to support himself by grinding at a mill; that while so occupied he wrote three plays and began his career as a dramatist. This account is said to be taken from Varro, but it contains some evident inconsistencies, and it is not improbable that it is a grammarian's construction, based upon supposed personal references in the plays and put together after the analogy of the literary Lives written by Greek grammarians. The uncertainties which attend the attempt to reconstruct the earlier Roman history are especially great in matters of literary history, which were not of sufficient importance to be officially recorded.

Of the writings of Plautus, 20 plays have come down to us, with considerable fragments of a 21st. But it is probable that these constitute only a part of his work. During the century of dramatic activity in Rome (c. 250–150 B.C.), there was no established theatre in the city, nor were there frequent presentations of plays. The genuine plays of Platus became confused with others which passed under his name, so that later traditions varied, some assigning to him as many as 130 plays, others as few as 21. There was during his lifetime no reading public, but in the half-century after 150 the plays came into circulation for reading and efforts were made by critics to distinguish the genuine from the spurious. This culminated in the fixing by Varro of a canon of 21 plays which were regarded by all critics as Plautine, and which are beyond reasonable doubt the plays that we now possess. Of the 20, the best known are 'The Captivi,' 'Trinummus,' 'Menaechmi' and 'Aulularia,' partly because they are most suitable for class-room reading; the 'Bacchides,' 'Pseudolus,' 'Rudens' and 'Miles Gloriosus' are superior to them in style and humor. About half the plays are corrupt in text, or fragmentary or of inferior merit.

The comedies of Plautus are based upon Greek plays of the New Comedy (c. 321–250 B.C.), and in a few cases Greek poets — Menander, Philemon, Diphilus — are named. His plays therefore illustrate that fusion of Greek form with Roman spirit which is generally characteristic of Latin literature. The plots, with their fundamental element of trickery, are wholly Greek, as are the characters and situations, at least in outline, and the subject-matter of the plays is the social and family life of a Greek city. Plautus was himself a man of Italian temperament; he was able to make the Greek plots and characters the vehicle for the expression of a genuine and original humor, to fill in the Greek outlines with the rich Italian coloring. In some plays, for example, in the 'Captivi,' the fusion is not complete and a certain degree of incongruity may be detected; in others, as in the 'Bacchides,' the hearty and almost riotous humor blends the two elements into a harmonious whole. That he truly expressed the spirit of his race is evident from his popularity during his lifetime and from the long-continued presentation of his plays upon the Roman stage. His comedy has not been without influence also upon modern literature; Molière founded his 'L'Avare' upon the 'Aulularia,' and Shakespeare's 'Comedy of Errors' is an adaption of the 'Menaechmi.'

Bibliography.— The best complete edition is the Teubner text by Goetz and Schoell, a condensation of the great critical edition begun by Ritschel in 1848 and completed by his three pupils, Goetz, Schoell and Loewe, in 1894. There are good commentaries on single plays by Brix and Lorenz, and in English by Tyrell and Sonnenschein. In Sellar's 'Roman Poets of the Republic' may be found an excellent essay upon the literary qualities of Plautus. No complete English translation has appeared since Thornton's (2d ed., 5 vols., 1769).

EDWARD PARMELEE MORRIS,
Retired Professor of Latin Language and Literature, Yale University.

PLAY. Various phenomena connected with the play of man and of animals have recently attracted the attention of both biologists and psychologists. These two lines of inquiry may be summed up in the two questions: (1) What is the function of play in the life of the organism? and (2) what are the essential psychological characteristics of play as distinguished from those of ordinary mental life?

In answer to the first question three theories have been advanced each of which seems to contain an element of truth. (1) There is the «surplus-energy» theory of Spencer according to which play is the natural outlet of the sur-

plus energy that has accumulated in a vigorous organism. (2) The "practice" theory worked out most fully by Groos according to which play has a positive function in the life of the animal as affording practice and preparation for the serious activities of life. (3) The "recuperative" theory that regards the play-activities as fulfilling their proper function in affording an opportunity for the rest or recuperation on the part of the other activities.

From the psychological side it has sometimes been held that "shamming" or semblance (often resulting in real self-illusion) is an essential of all play; but this mark does not seem to be present in all cases. The real differentia of play is perhaps found in the fact that the end of play is always the pleasure of the activity itself while work has always some end beyond the activity. Consult Spencer, 'Principles of Psychology'; Groos, 'The Play of Man,' and 'The Play of Animals.'

PLAY CENSORSHIP. A censor of plays, especially in Europe, is a person whose permission is necessary for the production of stage performances. A relic of the censorship of the press survives in Great Britain in the licensing of plays. By an Act of 1843, no plays may be acted for hire till they have been submitted to the Lord Chamberlain, who may refuse to license them in whole or in parts; the official who reads them for this purpose being the "examiner of stage plays." A penalty of $150 attaches to the offense of acting an unlicensed or prohibited play; and the theatre in which it is represented forfeits its license. In the United States there is no general censor, but local authorities have power to forbid the representation of plays which they consider to be injurious to morality.

PLAY OF COLORS, *in mineralogy,* the rapid display of different colors on revolving a mineral. It is this property which adds so much to the beauty of the diamond (q.v.) and other gems. The play of colors in many gems is due to their high refractive and dispersive power. The magnificent play of colors of the precious opal was attributed by Brewster to microscopic cavities, but Behrends has proved that it is due to thin, curved lamellæ of the mineral, the refractive power of which may vary by 0.1 from that of the mass. These lamellæ are assumed to have been originally in parallel positions, but they were bent and broken in the solidification of the mineral.

PLAY GROUNDS. See CHILDREN'S PLAY GROUND; RECREATION CENTRES.

PLAYA, plä'ya, mud deposits left by the drying up of temporary lakes in arid regions. They present a hard, barren surface, which shrinks and cracks under the sun's heat and in some instances becomes coated with efflorescent salts, resembling drifting snow. The Great Basin in the United States contains playa deposits of hundreds of feet in thickness. They are laid down by the desiccation during the dry season of large shallow lakes, known as sinks, holding in suspension a fine yellow silt, which form in the wet season. The deposits increase in depth by being thus intermittently covered by the silt-bearing water. Locally they are known by various names, such as mud-flats, salt-flats, alkali-flats, etc. The Black Rock Desert in Utah is an example.

PLAYBOY OF THE WESTERN WORLD, The, in three acts, by John Millington Synge, is a singularly arresting play by reason of its extraordinary combination of qualities that are ordinarily deemed contradictory. It is a comedy of Irish peasant life, extravagant, even boisterous at moments, yet based on the tragic theme of the murder of a father by his son; it is illuminated not only by the richest of humor but by poetic touches of poignant beauty, and all told in language so vivid and picturesque, so full of the zest and color of life, as to make ordinary English seem pale and tame,— "that vivid speech which has been shaped through some generations of English speaking by those who still think in Gælic" (W. B. Yeats).

Christy Mahon comes to a lonely public house foot-weary, a stranger and a fugitive. The kindly curiosity of the tavern keeper, his daughter, Pegeen, and others, wrings from him the confession that he has killed his overbearing father in a fit of anger with a blow from a spade. This evidence of courage and overmastering passion in a seemingly gentle lad so impresses his hearers that they talk themselves, and him, into the conviction that he is a hero. Inspired by his new-found confidence he makes love to Pegeen in one of the most delightful love scenes ever written, and Pegeen is quite prepared to throw over her prosaic husband-elect for Christy. When Christy's old father turns up, at this juncture, not much the worse for his broken pate, it is quite natural that there should be a sudden revulsion of feeling against Christy. He has lost his hold on their imaginations, and poor Pegeen, her romance shattered, leads the pack against him. The ultra-Nationalists professed to regard the play as an attack on Irish morals and character and organized hostile demonstrations when 'The Playboy' was first produced at the Abbey Theatre in Dublin in 1907, and later in London, and in the United States. In reality Synge has done the highest service to the Irish cause by creating dramas of artistic distinction and originality from purely Irish material. In his preface to the play Synge says, "I have used only one or two words that I have not heard among the country people of Ireland or spoken in my nursery." Another quotation from Synge furnishes a most significant commentary on 'The Playboy.' "On the stage one must have *reality* and one must have *joy;* . . . the rich joy found only in what is superb and wild in reality. . . . In a good play every speech should be as fully flavored as nut or apple, and such speeches cannot be written by any one who works among people who have shut their lips on poetry." 'The Playboy' is based on a story Synge heard in the Aran Islands; its language, its humor, its poetry, its flavor, its "reality," its "joy," are all drawn from Irish country folk and transmuted by the hand of the artist into an enduring work of art that is very human and very beautiful. For special references see article, RIDERS TO THE SEA.

GRACE R. ROBINSON.

PLAYERS' CLUB, The, social organization in New York City, with commodious headquarters at 16 Gramercy Park. Membership in the Club is confined as far as possible to artists, editors, authors, playwrights, etc., but eminent

lawyers and merchants are also eligible. The clubhouse was donated by Edwin Booth and was presented to the Club on 31 Dec. 1888. Nine directors, of whom five must be actors, playwrights or theatrical managers, manage the affairs of the organization.

PLAYFAIR, plŭf'fer, **John,** Scottish physicist: b. Benvie, Forfarshire, Scotland, 10 March 1748; d. Edinburgh, 19 July 1819. He was graduated from the University of Saint Andrews in 1765, entered the ministry in 1770 and held various livings; in the meantime devoting much time to mathematics; in 1785 he was appointed assistant professor of mathematics at the University of Edinburgh and in 1805 accepted the chair of natural philosophy there. He was secretary of the physical class in the Edinburgh Royal Society in 1789, subsequently general secretary and in 1807 was elected a member of the Royal Society. In 1815–16 he made a tour of France, Italy and Switzerland engaged in geological and mineralogical researches. He was a frequent contributor to the Endinburgh *Review* and his articles which are of great scientific value are collected in the 4th volume of the complete edition of his works edited by James G. Playfair (1822). He edited Euclid's 'Elements' (1705), and besides memoirs for the 'Transactions' of the Royal Society of Edinburgh, wrote 'Outlines of Natural Philosophy' (2 vols., 1812–16); 'Illustrations of the Huttonian Theory of the Earth'; etc.

PLAYFAIR, Lyon, Baron, British scientist and politician: b. Chanar, India, 21 May 1818; d. London, 29 May 1898. He was educated at St. Andrews, studied chemistry at Glasgow, and Giessen, became professor of chemistry at the Royal Institution, Manchester, in 1843, and held the same chair at Edinburgh, 1858–69. He represented Edinburgh and St. Andrews universities in Parliament, 1869–85, and thereafter represented South Leeds. He was postmaster general under Gladstone in 1873, and in 1880–83 was chairman and deputy speaker of the House. In 1892 he was created Baron Playfair of St. Andrews. He published 'Science in its Relation to Labor' (1853); 'Primary and Technical Education' (1870); 'Science in Relation to Public Weal,' etc.

PLAYGROUND AND RECREATION ASSOCIATION OF AMERICA, organized in 1906, endeavors to bring to every child and adult an adequate opportunity for wholesome use of spare time. Recreation, municipally supported the year round, is the association's chief objective. *Community Service,* a department of the association organized in 1919, assists communities in obtaining year-round recreation programs through private approach and support. Another department, the *National Physical Education Service,* established in 1918, promotes legislation for compulsory physical education in the schools. To supply trained recreation leaders, the association, in 1926, established the *National Recreation School,* giving a one-year course to prepare college graduates for community recreation leadership. Theodore Roosevelt was the first honorary president.

PLAYING CARDS. See Cards.

PLAZA, plä'sa, **Leonidas,** Ecuadorean statesman: b. about 1868. He received his education at the University of Quito and soon was launched into a political career, becoming president of Ecuador in 1901. Because of his opposition to the clerical element his path was a difficult one; nevertheless he was successful in placing the Church under state control and otherwise curbing its activity in the country. He had been some time in retirement when Estrada died in 1911, whereupon Plazo tendered his services. Two years of internecine strife followed in which Plazo vanquished his principal opponents, Alfaro and Montero and again became president. He made earnest efforts to rehabilitate the state's depleted finances, to resume payments of the foreign debt and inaugurated extensive and rather ambitious sanitary improvements. He was greatly hampered, however, by continued revolutionary outbreaks.

PLEA AND PLEADING. A plea is a presentation of a cause of action, made in a court, frequently a special answer to a bill of equity, making a charge or demand and requesting a judgment of the court in the first instance on the ground that the plaintiff is debarred from an answer required by the bill — such, for example, as a plea to the jurisdiction of the court. In a broader sense, it is a formal statement of the position of either party to a suit at law, in some of the lower courts it may be made orally, but usually it is a carefully prepared document, if for the defense, denying the plaintiff's declaration, in whole or in part, or alleging new matter, as a cause for annuling the action. A plea may be pre-emptory, that is meeting the issue squarely, as by denying the allegations or it may be dilatory, raising some technicality to delay the case. A Court of Common Pleas is one in which such pleas are heard, in the United States being usually equivalent to a County Court.

Pleading, in law, is the act of presenting a plea; a logical legal statement of facts constituting the plaintiff's cause of action or the grounds of a defense. It is the formal manner of alleging, as far as may be sufficient, that which either party to a suit expects to prove. The object of pleading is to make the matter in dispute between the parties plain and intelligible. The whole system of legal procedure applicable to the presentation of a case is also termed pleading. It is an initial step in the trial of a case. The term «special pleading» is often applied to a pleading that alleges new matter. See Demurrer.

PLEASANTVILLE, N. J., city in Atlantic County; alt. 30 feet; 6m. NW. of Atlantic City; on the Pennsylvania-Reading Seashore Lines. It is a residential suburb. To the east is the ocean; to the north, the Mullica River; to the south, Great Egg Harbor, and inland, to the west, the South New Jersey pine barrens. Fifteen miles distant, along the Tuckahoe River, are fishing and hunting grounds. Pop. (1940) 11,050.

PLEASANTVILLE, N. Y., village in Westchester County; 30m. NE. of New York; on the New York Central Railroad. It is a residential village, the home of many commuters to the metropolis. Its one industrial activity is printing. The village is eight miles from White Plains, the county seat. The recreational facilities of the county are within easy reach. The village has excellent schools. Pop. (1930) 4,540; (1940) 4,454.

PLEASONTON, Alfred, American military officer: b. Washington, D. C., 7 June 1824; d. there 17 Feb. 1897. Graduated from West Point in 1844, he served on the frontier and in the Mexican War; in 1862 served as major of the 2d Cavalry in the Peninsular campaign; promoted brigadier-general of volunteers, and commanded a division of cavalry in the Maryland campaign. At Chancellorsville he stopped the Confederate advance. In 1863 he was made major-general of volunteers, and led the cavalry of the Army of the Potomac at Gettysburg, earning a brevet of colonel in the regular army for gallantry in action. In 1864 he defeated General Price's forces at Marais des Cygnes, driving the Confederates out of Missouri. During his career he served in 105 battles. Retiring from the service, he was internal revenue collector and commissioner from 1866 to 1871, when he became president of the Terre Haute and Cincinnati Railroad. In 1888 he was placed on the U. S. Army retired list.

PLEBEIANS, plę-bē'anz (*Plebs*), an order of the Roman people, corresponding to the Commons of England. They differed from the *Clientes,* having no share in the *ager publicus;* they were obliged to serve in the army, but were excluded from all political privileges. The government of the state belonged exclusively to the Patricians, with whom the Plebeians could not intermarry. This was their condition under the kings. The subsequent domestic history of Rome is merely a record of struggles of the Plebeians to assert their claim to the place in the commonwealth. When Tullus Hostilius conquered Alba, he admitted the chief of its citizens to the Patrician class, while the rest were enrolled as Plebeians. The same course was followed in other conquests, so that the number of the Plebeians was constantly swelling, while they were of the same blood and possessed of the same courage, determination and other moral qualities as the dominant class.

The Plebeians, like the Patricians, were divided into *gentes,* but they were excluded from the three Patrician tribes and from the *curiæ,* which formed the governing class. Tarquinius Priscus seems to have made an attempt to introduce the Plebeians to the privileges of citizenship, but was not successful. Servius Tullius organized the Plebeians in tribes, of which he constituted four for the city and 26 for the surrounding subject territories. Each tribe had a tribune. They had their own social and religious privileges and were allowed to meet in *comitia tributa* convoked by the tribunes. A semblance of political power was at the same time conferred on them by Servius Tullius. He divided the whole body of citizens into five classes according to the amount of their property, upon which division was founded the *comitia centuriata* or great national assembly, to which the greater part of the legislative and judicial power of the *comitia curiata* was transferred. The citizens, in this assembly, voted by centuries, but as the equestrian order and the first class of citizens had the majority of the whole number of centuries, and voted first, it was only in the case of differences among them that it was necessary to consult the lower classes. Some of the noble Plebeian families were also admitted into the equestrian order. To follow the entire course of concessions which followed this beginning would demand an examination of the most complicated details of Roman history. The establishment of tribunes (494 B.C.), the law of the 12 tables (451–450 B.C.), the Lex Canuleia (445 B.C.), which permitted intermarriage; the admission to the consulate (366 B.C.), with the successive admission in 351 B.C. to the censorship, 336 B.C. to the prætorship and 300 B.C. to the offices of pontifex and augur, were the leading steps in a succession of victories which culminated (286 B.C.) in the Lex Hortensia, which gave the plebiscita of the people the force of law. From this time the privileges of the two classes may be said to have been equal; the word *populus* now began to be used to designate the whole people and *plebs* were employed sometimes to designate the assembly of the *comitia centuriata,* or popularly to distinguish the general mass of the common people.

PLEBISCITE, a form of voting introduced into France under the Napoleonic régime, and named after the Roman *plebiscitum.* It was a vote of the whole body of voters ratifying some legislative enactment.

PLECTOGNATHI, an order of physoclistous fishes, having incomplete ossification of the skeleton. Hard bony plates or spines cover the tough integument. The filefishes, trunkfishes, globefishes and the like are examples. See FISH; ICHTHYOLOGY.

PLECTOSPONDYLI, an order of soft-rayed fishes represented by the suckers (*Catastomidæ*), carps, etc. See ICHTHYOLOGY.

PLECTRUM, a small instrument made of ivory, horn, quill or metal, with which (having it in his right hand) the player on a lyra or cithara sets the strings in vibration. Plectra are used by performers on the mandolin and zither, and serves the double purpose of saving the fingers from friction, and of avoiding the deadening of the tones that results from the soft touch of the human hand.

PLEDGE, or **PAWN,** a species of bailment, being the deposit or placing of goods as security for the payment of money borrowed, or the fulfilment of an obligation or promise. It is distinguished, in English law, from a mortgage of chattels by the circumstance that the legal property in the chattel mortgaged is in the mortgagee, whereas the legal ownership of goods pawned remains in the pawner, though according to the definition of a pawn and and pledge the pawnee not only has the right of possession, but must be in possession. If the money is not paid at the time stipulated the pawn may be sold by the pawnee, who may retain enough of the proceeds to pay the debt intended to be secured. It is impossible to pledge a thing not yet made, as a machine contracted for but not built. The business of loaning on pledges is generally subject to license, and each State of the United States makes its own laws governing the conditions. See PAWNBROKERS.

PLEHVE, plē-vĕ, **Viatcheslav Konstantinovitch,** Russian public official: b. 1846; d. Saint Petersburg, 28 July 1904. He received a legal training at the University of Moscow and in 1867 entered the Department of Justice. He was for a time public prosecutor at Saint Peters-

burg and in 1881 was promoted to director of the department of secret police under the direction of the Minister of the Interior. In 1884 Plehve became senator and 10 years later was appointed Secretary of State for Finland. He directed and executed the government repressive measures there and earned the lasting hatred and enmity of all lovers of liberty. In 1902 he became Minister of the Interior and by his harsh measures so fired the Revolutionists that they caused his assassination.

PLEIADES, plī'ą-dēz, the daughters of Atlas by Pleione, daughter of Oceanus. According to one version of their story they committed suicide out of grief for the death of their sisters, the Hyades; but another version makes the fate of their father (see ATLAS) the impelling cause. According to a third version, they were companions of Artemis, and being pursued by Orion (q.v.), were saved from him by the gods and translated to the sky. The versions agree in declaring that the Pleiades were transformed into stars, where they are all visible save one, Sterope, who hides herself for shame that she alone of the seven married a mortal (she being the "lost Pleiad"); her sisters are Electra, Maia, Taygete, Alcyone, Celæno and Merope.

PLEISTOCENE (plīs'tō-sēn) **EPOCH,** in geology, includes the time that elapsed between the close of the Tertiary and the dawn of the historical or recent period. Measured in years, it is the shortest of the epochs, but geologically it is one of the most interesting. It includes the great Ice Age during which glaciers advanced and retreated across vast areas in North America and northwestern Europe. It is also the epoch, during which, so far as can be determined by the available evidence, man first appeared on the earth. For these two reasons it has been more discussed. Being so recent it left much evidence, not yet obliterated, of changes of land and water areas, and of variations in climate; but the very abundance of the evidence increases the task of deciphering and summarizing it, since for remote epochs only the great changes are known through the evidence of the rocks.

It is fairly certain that at the close of the Tertiary great areas in northern North America and Europe were more elevated than now. North America and Asia were perhaps united across Bering Strait; similarly the British Islands were part of a European continent that stretched out from Norway toward Iceland and north of Russia and Sibera over areas now covered by the Arctic Ocean. Regarding the equatorial land areas less is known, but possibly North and South America were united and it is possible that the Desert of Sahara was in part at least covered by an arm of the ocean. Of the distribution of land and water in the Antarctic regions the evidence found is not conclusive, though it is probable that the Antarctic continent was of greater extent than now, with a land bridge from Australia to South America. How much higher the land areas toward the north in Europe and North America were is uncertain, but it is probable that the regions about Hudson Bay and northern Sweden and Norway were much higher. The climate of these areas at the time was generally drier and cooler than it had been during the late Tertiary. During the early Pleistocene river valleys were deeply carved and the topography was strongly accentuated. Gradually the climate in the Northern hemisphere became colder, and possibly moister. What produced this change is one of the most baffling problems in geology. In the course of years perennial snow stood on the higher ground and gradually accumulating formed vast ice sheets or glaciers which slowly advanced from these higher regions over the regions southward, and in the case of such mountains as the Alps, to northward. Thus began the great Ice Age which lasted thousands of years. The ice sheets advanced, retreated and advanced again. Some of the retreats must have been of long duration. In fact the evidence from rock decay and the formation of soils leads some geologists to believe that the time that has elapsed since the final retreat and disappearance of the great continental glaciers is not as long as that of some of the interglacial intervals. The probable number and succession of the glacial advances and retreats and the work done by the ice in modifying the topography of the glaciated regions are discussed elsewhere. (See GLACIAL PERIOD). At the end of the Ice Age the regions in the North that had been the center of glaciation were much lower than at its beginning and the climate was moister. A subsequent elevation and a drier climate make the conditions governing life what they are to-day. Outside the glaciated areas the changes of level and climate have left less trace.

The advances and retreats of the ice necessarily meant great changes in climate. During the advances Arctic types of plants and animals were forced southward, during the retreats other types migrated northward, the Arctic types retreating or finding refuge on mountain ranges. One result of these migrations was the extinction of types that could not migrate readily and in particular of the great mammals. Man when he appeared waged war upon the large land animals that had withstood climatic changes. Thus it is that with the dawn of the historical period the fauna of Europe and America was impoverished as compared with periods immediately preceding, and the huge pachyderms, which, through Tertiary time, had been so striking a feature of the animal population of what are now the temperate regions of the world, disappeared, leaving only their gigantic remains to tell modern man the kind of monsters that have been the contemporaries of his prehistoric progenitors. See also QUATERNARY.

PLEKHANOFF, plê-kän'ov, **George,** Russian political economist; founder of the Russian Social-Democracy: b. 1857; d. Petrograd, June 1918. He was of noble origin, attended the Petrograd School of Mines, and at an early age joined the Populists (*narodniki*), later the *Zemlya i Volya* (Land and Liberty) Group. When the party split in the 70's, he stood at the head of the *Chorny Peredyel* (Black Division). In 1880 he was forced to seek refuge in western Europe and became contributor to *Narodnaya Volya* (*People's Liberty*), but his aversion to Blanquism brought him back to the field of Marxist thought. In 1883, while in France, and later while living in Switzerland, together with Axelrod and others, he was actively

agitating for the foundation of a Russian Social-Democratic Party, which from the start was dominated by the teachings of Karl Marx. His early pamphlets were 'Socialism and Political Action' (1883), 'Our Differences' (1884), and a translation and introduction to the 'Communist Manifesto.' (See MARX, KARL.) Plekhanoff's chief accomplishment in this period was an elucidation of the differences between Socialism and Anarchism, and a strong opposition to the latter. He was also opposed to the theory that the Russian people were better prepared for the Social Revolution than others because of their traditional agricultural communism and proved from the writings of Marx and Engels that this would not obviate the necessity of passing through the stage of Capitalism to Socialism. "Seizures of power", such as all Russian revolutionists since the days of the Decembrists considered possible, he regarded as foredoomed to failure owing to the lack of preparation on the part of the masses. Such seizure of power, he taught, could be undertaken only by a thoroughly trained working class. In the 90's Plekhanoff began to acquire a more international reputation, through his scientific economic studies, in defense and elaboration of the doctrine of economic determinism. His 'Contributions to the History of Materialism' places him at the head of those Marxists who would relate historic materialism closely with the physical sciences, and his book on Chernishevsky made western Europe aware of the existene of this great Russian thinker. The famous schism in the Russian Social-Democracy between *bolsheviki* and *mensheviki* took place in 1903, and Plekhanoff at once joined forces with the latter; but after the Revolution of 1905 he was embroiled with his former associates. He was now outside of both factions, and this situation was emphasized further by the outbreak of the War in 1914. Plekhanoff became a patriot and insisted on the necessity of a victory of the Entente Powers over the Central Empires, and therefore of supporting the government of the Tsar in the war. He therefore found himself, on his return to Petrograd from Switzerland (where he had spent all the years of his maturity), after the Revolution of March 1917 at variance with both mensheviki and bolsheviki, and was able to retain leadership only of the small Yedinstvo (Unity) Group, which had practically no influence on the course of the proletarian revolution which came into power in November 1917. The last few months of his life were no doubt embittered by the opposition of the entire working class population of Petrograd, which, weary of long months of hardships, was eager for a termination of the war, which consummation Plekhanoff was actively resisting, going so far as to ally himself with the Cadet Party and the military and bourgeois organizations in the pursuit of this end.

JACOB WITTMER HARTMANN.

PLEOCHROISM. See PHYSICAL CRYSTALLOGRAPHY.

PLESIOSAURUS, a genus of extinct reptiles of the order *Sauropterygia.* Several species have been described from very complete remains in European Lias rocks, first discovered in 1822 and studied by Cuvier and his followers. In these reptiles the head is small, the neck very long, the tail of moderate length. The typical species is *P. dolichodirus,* about 10 feet long; allied species are sometimes found 25 feet long. There is a fine skeleton preserved in the Berlin Museum, classified as *P. guilelmi imperatoris.* Over 25 species have been recognized in the Liassic seas of England, and they are also common in the continent of Europe. In the United States related species have been located in the Upper Jurassic and Upper Cretaceous. One of these uncovered at Fort Wallace, Kans., and known as Cope's *Elasmosaurus* had a neck 22 feet long and a total length estimated from the incomplete skeleton of at least 42 feet. These monstrous lizards swallowed stones like modern fowl, to aid their digestion. Their food was undoubtedly fish, as their dentition was adapted to grasping and tearing. It may reasonably be inferred that these reptiles were aquatic and inhabited the estuaries of rivers and shallow waters, occasionally swimming out to sea. Their gait on land would necessarily be awkward and difficult. The elongated neck would serve to enable them to descry their prey from among or over the tops of the reeds and vegetation amid which they might lie concealed in the banks of rivers or in estuaries, while this same length of neck would adapt them for readily seizing their prey, which consisted probably in greater part of fishes. Some have thought that a few remain, and that their long necks and small heads have caused them to be taken for swimming serpents, thus accounting for the ever-recurring accounts of sea-serpents. Consult for particulars of structure Woodward, 'Vertebrate Paleontology' (1898); and Williston, S. W., 'North American Pleiosaurs' (in 'Field Columbian Museum Publication 73,' Chicago 1903).

PLESSIS, plĕ-sē, **Joseph Octave,** Canadian Roman Catholic bishop: b. near Montreal, province of Quebec, 1763; d. Quebec, Canada, 4 Dec. 1825. He was educated at the Petit Séminaire, Quebec, taught belles-lettres and rhetoric at the College of Montreal, was ordained in the priesthood in 1786, and soon afterward became secretary to Bishop Hubert. In 1792 he was appointed curé of Quebec, and later became coadjutor to Bishop Denault, despite the opposition of the governor of the province, who feared the influence of Plessis with the French Canadians, and in 1806 succeeded Bishop Denault in the see of Quebec. An effort made to introduce an exclusively Protestant system of instruction, and an attempt to prevent his taking the oath of allegiance as bishop resulted in the recall of Governor Craig. Sir George Provost was appointed in his stead, and the demands of the bishop were conceded. During the War of 1812 the bishop loyally supported the English, and thereby gained the favor of the government, he was then recognized in his office of bishop, granted a seat in the legislative council, and was pensioned. In 1818 he was nominated archbishop of Quebec. Consult 'Life' by Ferland (1864).

PLETHO, surname of Georgios Gemistos (often called Gemistus Plethon) Byzantine scholar and philosopher of the 14th and 15th centuries: b. Constantinople. For many years he was the head of a philosophical school at Misithra in the Peloponnesus. He went with

the Emperor John VIII, Palæologus, to the council at Ferrara, and remained until 1441 in Italy, where he gave great impetus to Greek studies, and was the means of establishing the Platonic Academy of Cosmo de' Medici. His treatise in praise of Platonism inaugurated the long quarrel between the disciples of the two great masters of antiquity, which produced a profound study of their systems. Pletho, however, mingled with the Platonic philosophy the notions of the later Alexandrian school and of the spurious writings attributed to Zoroaster and Hermes. The best collection of his writings is in Migne's 'Patrologia Græca' (Vol. XIX, Paris 1866). Consult Schultze, 'Pletho, und seine Bestrebungen' (1874).

PLETHORA, or **HYPERÆMIA,** a condition of overfulness of the blood-vascular system, a condition in which there is obvious excess of blood in the body. It can hardly be called a disease. That is to say, the quantity of blood may be in excess of the normal, but its quality may be unaltered. On the other hand, there is a condition of plethora, called by pathologists hydræmic plethora, in which there is not only excess in the total volume of blood, but the excess is due to retention of water, so that the blood is more watery than usual. But the term plethora as ordinarily used signifies simply excess of blood.

Amputation is a frequent cause of plethora, as the digestive powers do not immediately accommodate themselves to the reduced wants of the system, and too much food is liable to be taken and too much blood formed. Plethora has two leading causes — the introduction into the vascular system of too much nutriment, and the deficient activity of tissue-change in the various organs, whereby the nutritive matter is insufficiently removed from the blood. A tendency to plethora thus generally develops at an advanced age, when the activity of tissue-processes has been considerably diminished. Plethora is often confounded with obesity, from which it is quite distinct. Plethoric persons, however, are usually unduly stout, much of the excess of nutritive material being deposited as fat under the skin. Plethora produces a diminution of activity and a greater tendency to sleep than belongs with health; these symptoms increase as it becomes aggravated, and culminate in lassitude and vertigo, turgid countenance, suffused eyes, palpitation of the heart, and similar phenomena. The treatment of plethora is entirely negative, and is suggested by the causes of the disease. Abstinence and exercise are its two most important elements, and their combination depends upon the circumstances of the individual case. Generally abstinence from malt liquors, wines or spirits is recommended.

PLEURA, the serous membrane lining the cavity of the thorax or chest, and which also covers the lungs. Each lung is invested by a separate pleura or portion of this membrane; the structure being spoken of rather as double pleuræ than as a single membrane. Like all serous membranes, each pleura is a completely closed or shut sac, and does not communicate with its companion membrane; and it further resembles the other serous membranes in that one side or part of the sac lines the containing cavity, while the other part or fold is reflected over the contained organs. In the thorax, therefore, each pleura is found to consist of a portion lining the walls of the chest, this fold being named the *pleura costalis* or parietal layer of the pleura. The other fold, reflected upon the lung's surface, is named in contradistinction the *pleura pulmonalis,* or the visceral layer. These two folds enclose a space known as the pleural cavity, which in health contains serous fluid in just sufficient quantity to lubricate the surfaces of the pleuræ as they glide over one another in the movements of respiration. In front the two pleural sacs touch one another at a single point only, about the middle of the sternum, and they therefore enclose a space between them known as the mediastinum, which is again divided into anterior, middle, posterior portions. In the mediastinal space the heart and other organs of the chest, excepting the lungs, are situated. The pleura lines the ribs laterally, and a portion of the sternum or breast-bone in front. From the breast-bone it passes backward over the pericardium. The pleura of the right side is wider, shorter and extends higher in the neck than that of the left side. The outer aspect of the membrane adheres to the lung-surface, and also to the pulmonary vessels as these leave the pericardium. It is also attached to the diaphragm below; elsewhere it is but loosely connected to the contiguous surfaces. It is supplied with blood vessels from the internal mammary, intercostal, phrenic and other arterial trunks; its veins corresponding in nature to the arteries. Its nervous supply is derived from the phrenic and sympathetic nerves, while the absorbent or lympathic vessels are also numerous.

The diseases to which the pleuræ are subject are chiefly pleurisy or inflammation of the membrane; pneumothorax, with or without effusion of fluid into the pleural cavity (hydrothorax), and empyema. Hæmothorax, or blood in the pleural cavity, generally results from accidental wounding of the intercostal arteries. Inflammation of the pleura of itself may terminate in hydrothorax or empyema, the inflammatory products in this, as in other cases, appearing in the form of serous fluid or pus respectively. See PLEURISY.

PLEURISY, an inflammatory disease of the pleura (q.v.). It is either dry or accompanied by effusion. Dry or fibrinous pleurisy is characterized by an inflamed area, usually of small extent, covered with a layer of plastic lymph and somewhat roughened. Its invasion is accompanied with sharp pain and a dry cough, and friction-sounds are heard on placing the ear to the chest. Adjacent portions of the membrane may adhere together, forming adhesions which become permanent and limit the movements of the lung. Pleurisy is usually due to cold, unless secondary to another disease, such as penumonia, tuberculosis or cancer. Frequently an arrest of the inflammatory process occurs, and the fibrinous layer disappears from the surface of the pleura by absorption. If not, there may be an effusion of serum into the space between the two layers of the pleura. The amount of effusion may be so great as to cause serious displacement of the lung or heart. If small in amount the fluid is often reabsorbed; but otherwise it must be removed by tapping. The fluid at first is pale and yellowish, or stained with blood-pigment. Later it becomes

turbid, and if it becomes infected by bacteria carried into the pleura by the lympathics, or entering through a penetrating wound or during the progress of malignant disease or tubercle, it is converted into purulent matter. The condition is then termed empyema, or chronic purulent pleurisy, and is grave. The pus may penetrate the wall of the pleural cavity and the lung-tissue and burst into a bronchial tube and be coughed up. Or it may perforate the diaphragm, enter the peritoneal cavity and cause a purulent peritonitis. Few cases recover without surgical treatment which consists of opening the suppurating cavity and providing drainage.

In all pleurisy breathing is apt to be shallow and difficult, and general weakness, loss of appetite, headache and rapid pulse are noted. When pus appears in a pleural cavity there is an irregular temperature, a succession of chills and recurrent sweats. Upon the entrance of fluid into the pleura the friction-sounds disappear, and a dullness and later a flatness is ascertained by percussion over the position of the effusion. Wet or sero-fibrinous pleurisy may continue for months, and the compressed lung may never expand again to its former volume, but may become "carnified." Tuberculous pleurisy occurs as a result of tuberculosis of the lung, in a vast number of cases, as a primary disease. As a secondary implication, dry pleurisy always occurs when the tubercular process reaches the surface of the lung. Hemorrhagic pleurisy, or pleurisy with a bloody effusion, occurs frequently in cases of cancer, Bright's disease and certain fevers, as well as in tuberculosis.

According to the situation of the lesion, pleurisy is termed diaphragmatic or interlobular. When limited by adhesions which form pockets, it is termed encysted. In the treatment of pleurisy little medicine is used. A cathartic is desirable at the outset. Adhesive-plaster straps are employed, fastened around the chest, or half of it, to secure immobilization of the affected side. An ice-bag gives relief from pain and limits the inflammation. Counter irritation may be secured with iodine or mustard, but blisters and cups are now seldom employed. Vapor baths, to cause diaphoresis, and diuretics are rarely required. Salicylates are useful in some cases. Aspiration of the fluid is secured by means of a hollow needle to which a suction-pump is attached, a method invented and introduced by Wyman of Cambridge and Bowditch of Boston. The needle is inserted generally in the axillary line and the operation is practically without risk. The fluid is withdrawn slowly, and even as much as a quart may be removed with safety. Often after a small fraction of an effusion is removed the remainder will be absorbed spontaneously. In cases of empyema a free incision is usually made and open drainage secured. Sometimes it is necessary to reset a part of one or two ribs. After recovery from empyema the chest is usually sunken and flattened.

PLEURISY-ROOT, a perennial herb of the genus *Asclepias* (q.v.).

PLEURONECTIDÆ. See FLATFISH.

PLEUROPNEUMONIA, a disease common to cattle, and occasionally communicated to other domestic quadrupeds. It is highly contagious, and exceedingly fatal, though a certain proportion of animals recover. It first manifests itself in a morbid condition of the general system; but its seat is in the lungs and the pleura, where it causes an abundant inflammatory exudation of thick plastic matter. The lungs become rapidly filled with this, and the animal suffers from cough and difficulty in breathing. Many die in the course of a few days. It is believed to have been wholly eradicated in America and Europe. Consult Atkinson, V. T., 'Special Report on Diseases of Cattle' (Bureau of Animal Industry, Washington 1912). See CATTLE-PLAGUE; RINDERPEST.

PLEVNA, plĕv'nạ, or **PLÉVEN,** Bulgaria, the chief town of the district of the same name, about four miles east of the Vid, a tributary of the Danube. Plevna commands a number of important roads, hence is a place of some strategical importance. It is noted for the gallant resistance of its Turkish garrison under Osman Pasha to the Russians during the Russo-Turkish War of 1877–78. Osman intrenched himself here in the early part of September, and the Russian attempts with superior forces to take the place by storm were failures. When food and ammunition had run short he made a bold effort to cut his way through his enemies, but was compelled to capitulate with 40,000 men (10 Dec. 1877). The Russians had to assemble a force of 100,000 men and starve the garrison before victory was accomplished. The area of the district is 2,948 square miles. In 1926 the population of the district was 431,804, and that of the city, 28,775. Consult Herbert, W. V., 'The Defense of Plevna' (London 1896).

PLEXIMETER. See PERCUSSION.

PLEYEL, plī'ĕl, **Ignaz,** Austrian composer: b. Ruppertsthal, near Vienna, Austria, 1 June 1757; d. Paris, France, 14 Nov. 1831. He studied composition under Haydn, and in 1786 made a tour through Italy and France, where he was everywhere received with the greatest favor. In 1787 he was appointed chapel-master to Strassburg cathedral; but in consequence of the revolution he was obliged to flee. He proceeded to London; became again connected with Haydn, and gave a series of concerts in 1791–92. He soon after went back to France, and at a later period founded a musical business and piano factory which became one of the most important in Europe. In 1801 he commenced editing the 'Bibliothèque Musicale,' in which he inserted the best works of the Italian, German and French composers. His own works, chiefly instrumental pieces, are light, pleasing and expressive. The earliest of them are the best. One of the most popular is the well-known hymn tune which bears his name.

PLICA, PLICA POLONICA, or **TRICHOMA,** a condition formerly regarded as a disease, indicated by a matting of the hair of the head or body, in which the hair becomes agglutinated by a nauseous exudation from the roots, the bulbs become enlarged, and the hair swells and becomes soft. Plica is said to have appeared in Poland and adjacent districts about the end of the 13th century, and is now gradually wearing out. The condition is usually kept up by neglect, being deemed a safeguard against some internal disease, and no means being taken

to remove it. The treatment of plica is for the most part empirical, and beyond cleanliness and attention to diet there appears to be nothing in regard to it determined with certainty.

PLIMSOLL, plim'sŏl, **Samuel** ("THE SAILORS' FRIEND"), English reformer: b. Bristol, 10 Feb. 1824; d. Folkestone, Kent, 3 June 1898. Through his occupation as a coal dealer he became interested in the condition of sailors, and the dangers to which they were exposed by unscrupulous overloading of heavily insured vessels induced him to enter Parliament in 1868 as member for Derby. In 1873 he published 'Our Seamen,' which succeeded in its purpose of arousing public attention, and in 1876 the Merchant Shipping Act, embodying many of his demands, was passed. Among its provisions was the load line known as the «Plimsoll line,» which has since been marked on all English ships. He also wrote 'Cattle Ships' (1890), with reference to securing reform in that direction.

PLINLIMMON, plin-lĭm'mŏn, **PLYNLIMON,** or **PUMLUMON,** Wales, a mountain-mass on the boundary between the counties of Montgomery and Cardigan, 10 miles west of Llamidloes. It has three principal summits (although the name means "five beacons"), attaining a maximum altitude of 2,468 feet. The Severn and the Wye rivers rise on its slopes.

PLINTH, in architecture, the lower square member of the base of a column or pedestal. In a wall the term plinth is applied to two or three rows of bricks which project from the face. See ARCHITECTURE; COLUMN.

PLINY, plin'y (GAIUS PLINIUS SECUNDUS), commonly called Pliny the Elder, Roman author: b. Novum Comum, 23 A.D.; d. Stabiæ, 79 A.D. He came to Rome at an early age where he availed himself of the best teachers. He served in Germany under Domitius Corbulo and Pomponius Secundus, and obtained the command of a troop of cavalry. During the intervals of his military duties he composed the treatise 'De Jaculatione Equestri,' and began a 'History of the Germanic War,' which he subsequently completed in 20 books. Apparently he fought in the Jewish war and was made procurator of Syria. It is known that he was also appointed procurator of the emperor in Spain. His nephew, Pliny the Younger (q.v.), has left an account of his life at this period, which was one of constant study. He made extracts from all the books he read, or had read to him, and at his death left his nephew 160 volumes of these notes. His 'Natural History,' compiled from materials accumulated in this way, was published about 77. This is his only extant work. He perished in the eruption of Mount Vesuvius which overwhelmed Pompeii and Herculaneum in 79. The 'Historia Naturalis' is divided into 37 books, and is, according to his own account, a compilation from upward of 2,000 volumes. It embraces the domain of natural history in the widest sense, including astronomy, geography and meteorology. It even goes beyond what natural history in any sense would include — treating of the fine arts and human institutions and inventions. The first edition was published at Venice in 1469. The edition of Hardouin 1685 is the first critical edition. The edition of Panckouke (1829–33), with a French translation, and notes by eminent modern naturalists and scientific men, including Cuvier, is of great value. The best editions of the text are those of Sillig (1851–58) and Detlefsen (1866–73). Pliny was translated into English by Philemon Holland (1601, two vols. folio). There is a translation (1855) in Bohn's Classic Library by Bostock and Riley. Pliny has been the chief source from which historians have obtained color and detail to embellish their descriptions of life at the opening of the Christian era. While his accumulations were not scientific in the modern sense, and while he did not have the trained sense of a modern encyclopedist, yet he was an indefatigable worker, and has passed on to the modern a vast amount of early erudition which otherwise would have been lost. Consult Mayhof's republication of Jan's 1875 edition of Pliny's works (1909).

PLINY (GAIUS PLINIUS CÆCILIUS SECUNDUS), called Pliny the younger, Roman author: b. Novum Comum, 62 A.D.; d. about 113. He was a nephew of Pliny the Elder, by whom he was adopted and carefully educated. He studied at Rome under Quintilian and Nicetes Sacerdos, in 76 wrote a work in Greek — "What it was I know not; it was called a tragedy" — and in 81 made his first appearance as an advocate by pleading a case before the centumviri. After service in Syria as tribune of the third legion, he entered public life, becoming successively quæstor Cæsaris (emperor's quæstor; 87), tribune of the plebs (91), and prætor (93). He was then forced by the conditions of Domitian's government to withdraw from his office; and the discovery among Domitian's papers of a charge of treason against him makes it evident that his life was saved by the tyrant's assassination (96). In September 100 he became consul (with Cornutus Tertullus). Trajan, with clear appreciation of Pliny's administrative talents, made him augur (104 or 105), and later curator of the channel and banks of the Tiber and of the municipal drainage system. He was sent out in 111 as governor with special powers of the province of Bithynia. His official correspondence with the emperor ends in 113; and he then disappears from view. His miscellaneous letters are the best extant contemporary authority for an important period of Roman history. Those to and from Trajan afford the chief documentary evidence for the study of Roman provincial government; and they contain, also, the earliest information *ab extra* of the manners of the primitive Christians and their official treatment by the Roman administration. Through the extent and variety of his own works, supplemented by inscriptions discovered at Novum Comum, Pliny is perhaps more fully and accurately known than any ancient writer save Cicero. His letters, however, unlike those of Cicero, were evidently written and arranged for publication. The order is largely chronological, although, to give an impression of carelessness, slight deviations appear within the individual books. The diction is clear and smooth; and if, as Simcox thinks, his "boundless self-complacency found here a safe opportunity for expansion," there is also manifest throughout a certain tone of culture and distinction which quite reconciles to any

such quality. Of Pliny's verses nothing remains and of his published speeches only a fulsome panegyric on Trajan whose florid style probably represents his oratorical attempts to imitate Demosthenes. The best edition is that of Keil (1873), who established the text and was aided by Mommsen. There are also many other excellent editions in whole or in part. There is an English version of the letters by Lewis (1880). Consult also Church and Brodribb, 'Pliny's Letters (1872) in Collins' 'Ancient Classics for English Readers'; and Schanz, Martin, 'Geschichte der Römischen Litteratur' (Munich 1913).

PLIOCENE, according to Geological Survey usage, the latest epoch of the Tertiary period. It is preceded by Miocene, and followed by Pleistocene. Some authorities give it the rank of period. During this epoch the continent of North America had very nearly the same outline as at present, though a very narrow strip of marine beds on parts of the Atlantic and Gulf coasts show that at least for part of the epoch the sea had encroached on the land. Florida was largely under water. A narrow belt of marine beds also exists on the Pacific Coast. Rather general uplift of the continent took place near the close of Pliocene time. The connection with South America, broken during Eocene (q.v.) time, was re-established during the Pliocene, with a resultant mingling of the faunas. The life of the epoch was not greatly different from that of modern times. The horse, which originated in the United States, had developed to its present genus. The rhinoceros, the mastodon and the sabre-toothed tiger were all present, though they ceased to exist on this continent during the Pleistocene. In Java, a skeleton has been found in Pliocene rocks, that may possibly represent an ancestral man. It has been called Pithecanthropus erectus (q.v.).

PLIOHIPPUS. See Horse, Evolution of.

PLIOSAURUS. See Plesiosaurus.

PLOCK, plŏtsk, or **PLOTZK,** German Poland, (1) town, capital of the district of Plock, on the right bank of the Vistula, 60 miles northwest of Warsaw. It has no less than 25 squares, of which one in the old town is very regularly built. It has a handsome cathedral, a considerable trade and several large fairs. Pop. about 25,800. (2) The district of Plock has an area of 3,641 square miles of level and moderately fertile territory. It was overrun by the Germans in 1914–18 and 1939 and sadly damaged. The region is agricultural; wheat, rye and oats are grown and milled; there is a considerable beet-sugar industry. Lumber is cut and shipped. The Vistula is the principal river, but the Drewenz, which forms part of the northern boundary with Prussia, is a stream of good size. Pop. 786,000.

PLOMBIERES, plăṅ-bē-ār, France, a health-resort in the department of Vosges, 14 miles south of Epinal. It became fashionable during the Second Empire through the favor of Napoleon III, though the virtues of its waters were known ever since the times of the Romans. There are nearly 30 springs, ranging in temperature from 66° to 150° F.; their waters are in great repute against skin diseases, gout, rheumatism, dyspepsia, female complaints, etc. A handsome casino was opened in 1876, and there are picturesque walks and a park in the valley in which the village stands. Permanent population (1926), 1,565.

PLOTINUS, plō-tī'nŭs, the most famous of Neo-Platonists: b. Lycopolis, Egypt, about 204 A.D.; d. Minturnæ, Campania, 270. In his intercourse with his pupils and acquaintances he avoided all reference to the antecedent circumstances of his life, his age, nativity or parentage. It is conjectured that he was of Roman descent, probably a freedman. It was in his 28th year that the desire to study philosophy awoke in him. He then fell into great despondency and was brought by a friend to Ammonius Saccas, a Christian, who had written some works on Christian theology, but returned to the Hellenic faith. He remained with him some 10 years. In 242 he joined the expedition of the Emperor Gordian to the East, in order to learn the philosophy of the Persians and Indians. After the death of Gordian he went to Rome where he subsequently lived and taught. About 254 his friends induced him to put his doctrines in writing. The works of Plotinus were highly valued by Longinus, although that philosopher was in no sense a Plotinist, and are distinguished by energy and enthusiasm. He was in fact a preacher. His teaching secured him great respect and popularity among those who did not receive Christianity. Parents left their children to his care, and his house was full of orphans of both sexes entrusted to his guardianship. Although neglectful of his own temporal interests, he showed no want of shrewdness in looking after the estates of his wards. Plotinus enjoyed the favor of the Emperor Gallienus, from whom he obtained the privilege of rebuilding at the expense of the government two destroyed towns in the Campania, with a view to their being governed according to the laws of Plato. Plotinus was one of the great masters of philosophy. The value of his system depends less upon the intrinsic truth it contains than upon its historical importance and its adaptation to a certain class of human sympathies. The historical value of the system, great both in its antecedents and consequents, is due partly to the circumstances out of which it arose and partly to the genius and originality of its founder. It had its source at the junction of two independent streams of thought; mysticism and dialectics, which, already fortuitously united, received a new direction from the individual energy of the mind of Plotinus. He was well acquainted with the older Greek philosophy, the Ionian and the Eleatic schools etc., and according to the eclectic tendencies of his day believed there was a fundamental unity in these various systems. It was to Plato, however, that he looked as his great authority. He believed himself a strict follower of Plato uses Plato's term, the Good, for his highest generalization; but with Plotinus it is an abstraction from which every determinate quality has been eliminated and would rather be described in modern philosophical language as the Absolute. Consult Jones, Rufus M., 'Studies in Mystical Religion' (1909); Guthrie, K. S. 'The Philosophy of Plotinus' (1910); Inge

W. R., 'The Philosophy of Plotinus' (2 vols., 2nd ed., London 1923).

PLOTZ, plätz, **Harry,** American bacteriologist: b. Paterson, N. J., 1890. In 1913 he was graduated at the College of Physicians and Surgeons of Columbia University and in 1914 discovered the bacillus of typhus. He subsequently proved the identity of Brill's disease with typhus and in 1915 he brought out a vaccine against typhus. The authorities of Mount Sinai Hospital sent him to Serbia in 1915, with a complete vaccination apparatus, in an effort to stem the tide of the typhus epidemic then raging in that country.

PLOVER, the general name employed to designate most birds of the limicoline family *Charadriidæ,* of which the true plovers are sometimes held to constitute the subfamily *Charadrinæ,* and to that extent are separated from the turnstones and surf-birds (qq.v.). Closely related are the sandpipers and snipes (qq.v.). The plovers have a short or moderate bill, never exceeding the head, soft basally, but horny, somewhat enlarged and usually slightly hooked at the end. The legs are comparatively short and, with only a few exceptions, have no hallux, and the three remaining toes are not much lengthened. The body is full and plump, the neck short and thick and the head large. The long pointed wings reach to the tip of the short, 12-quilled tail. Plovers are small or moderate sized birds, remarkable for their extensive migrations and found along the seashore or in plains and fields. They are strictly ground birds and with few exceptions lay four speckled pyriform eggs in a slight depression in the ground. About 75 species are known from all parts of the world, some of the exotic ones exhibiting remarkable modifications. Within the limits of North America there occur three genera and 13 species, all closely related. The most distinct of these is the lapwing (*Vanellus vanellus*), known by its crested head and long overlapping wings, a rare straggler from Europe which scarcely belongs to our fauna. To the genus *Charadrius* belong the black-bellied or bull plover (*C. squatarola*) and the golden plovers (*C. dominicus*), *et al.* The former is nearly a foot long, and in the breeding plumage has the under parts largely black, but in the autumnal plumage, as usually seen in the United States, the black is limited chiefly to the axillary region. This plover may be distinguished at once from any closely related American species by the presence of a distinct hind toe. It breeds in the far north sparingly as far south as Minnesota, and undertakes the most stupendous migrations, reaching South American on our side and South Africa, Australia and Tasmania on the other. It migrates in flocks both coastwise and in the interior; and is equally common in this country and Europe where it is called the gray plover. The American golden plover (*C. dominicus*), also known to gunners as the field plover and bull-head plover, is only slightly smaller than the last, from which it is easily distinguished by the absence of a hind toe and the paler finely mottled plumage, the upper parts of which have much golden-yellow in summer. This species breeds in Arctic America and winters as far south as Patagonia, passing through the United States as a transient in the spring and again from August to November. At the latter season their numbers are augmented by the young of the year, and they migrate in great flocks or waves which often linger for several weeks in neighborhoods where food is abundant. Consult Elliot, 'North American Shore Birds' (New York 1895); Sandys and Van Dyke, 'Upland Game Birds' (New York 1902); Murphy, 'American Game Bird Shooting' (New York 1882); besides the standard works on ornithology.

PLOW, an implement originally drawn by horses, oxen, etc., used for breaking up or loosening the soil, preparatory to planting or sowing. The plow was the primary implement of civilization. The cultivation of the soil, which began with the invention of the plow, made it possible for men to live in permanent, populous communities, and civilization found a foothold wherever the pastoral tribes of the Stone Age learned the lesson of industry by following the plow. According to an Egyptian legend, "Osiris taught the way and manner of tillage and good management of the fruits of the earth." It was undoubtedly in the valley of the Nile, or the Euphrates, that the plow was invented, for in these valleys are found the oldest ruins of agricultural settlements.

The first plow was roughly fashioned from a forked tree. One branch served as the beam, while the other branch was cut off and pointed, and the tail was trimmed to form a handle. Plows of this crude type are pictured on Egyptian monuments. After bronze tools came into use, it was possible to make a more finished and efficient plow of dressed timbers, and many variations are found in the forms of wooden plows that were used 2,000 to 4,000 years ago. In the prevailing type, a block of wood, with the front end pointed or wedge-shaped, served as the bottom, to which the beam and a single handle were attached. In Latin America, and in many other parts of the world, wooden plows of this form, with iron points and one handle, are in use to this day. The extension of agriculture and civilization in Europe awaited the introduction of iron for plow points, which occurred shortly before the Christian era.

The ancient plow merely stirred or loosened the soil. Modern plows cut a furrow and turn it over so as to cover the sod and weeds, and leave fresh soil on the surface as the seed bed of the crop that is to be planted or sown. English and American patent records show the evolution, in the past two centuries, of the modern form of plow. The Colonial plow, which was used in the United States until the beginning of the 19th century, reflects English ideas in plow-making. The point was of wrought iron, sometimes tipped or edged with steel. The moldboard and all the other parts were of wood, but in some cases the moldboard was covered with sheet iron.

In 1797 Charles Newbold, of New Jersey, patented a cast-iron plow in which the share and moldboard were cast in one piece, but this plow did not prove successful, as the cast-iron point would soon wear off, and farmers could not afford the cost of renewal of so large and expensive a casting. The most practical improvement of this period was made by Richard B. Chenaworth, of Baltimore, one of the first

manufacturers of farm implements in the United States, who patented, in 1813, a cast-iron plow in which the share, moldboard and landside were cast in separate pieces. Jethro Wood, of New York, who took out patents in 1813 and 1819 on improvements in cast-iron plows, has been given credit for important work in the introduction of improved plows, although the main feature of his patent of 1819 was not a practical invention. He never engaged in manufacturing, and was unsuccessful in obtaining any income from royalties or licenses under his patents, but he gave his entire life to the work of advocating the use of cast-iron plows.

To James Oliver, of South Bend, Ind., is due the credit for the invention of the chilled plow. He began the manufacture of plows at South Bend, Ind., in 1855. When iron is cast in a chill, that is, in a mold one side of which is a metal vessel filled with water, the sudden cooling of the molten iron in contact with the chill gives the casting a surface as hard as the hardest steel. But the chilled metal was not strong enough to stand the hard usage that a plow receives in the field, and it was impossible to prevent flaws and blow holes in the broad face of a moldboard. After many years of effort, Mr. Oliver mastered the problem. His first success was obtained in chilling the wing or outer end of the moldboard, where the friction with the soil is greatest and he ultimately succeeded in this purpose by the use of three inventions. The first consisted in the use of a chill filled with hot water. The heat dried out the moisture of the sand in the mold, and this obviated the flaws and blowholes that were caused by steam, which had been generated when the molten metal was poured into the mold. The next invention was the ventilation of the chill by means of checkered grooves on its face, which permitted the air and hot gases from the metal to escape from the mold. These two inventions produced a chilled casting which was free from flaws, but moldboards cast in this manner were not strong enough to stand ordinary usage in the field. This last difficulty was overcome by the invention of an annealing process which tempered and strengthened the moldboard without detracting from its wearing and scouring qualities and made the chilled plows a complete success.

A few of the notable improvements that have been patented by James Oliver are: The cast share, with chilled point and cutting edge, made by a simple process; the share with an upward, coulter-like extension, which fits against the front edge of the moldboard and gives a new vertical cutting edge to the plow when the share is renewed; the curved malleable standard, which brings the beam over the line of resistance of the plow; the simple adjustment of the beam, which makes the plow balance perfectly with two or three horses; the malleable gauge wheel, which regulates the depth of the furrow; and other devices to simplify and improve the work of the plow.

The next improvement in plows was the sulky or buggy plow, having two wheels and a seat, also a lever for regulating the depth of the share. Then came the gangplow or multiplow, drawn by a tractor instead of horses. For such plows the share and moldboard was often impracticable so the disc-plow was invented, consisting of a circular disced metal share that turned the soil as it rotated. A variety of plows are manufactured for special uses, as for ditching, plowing on a side-hill, for paring sod, or for cultivating particular crops. See AGRICULTURE.

PLOWDEN, Edmund, English jurist: b. Plowden, Shropshire, 1518; d. 6 Feb. 1585. He was educated at Cambridge and Oxford, admitted to practice physic and surgery in 1552 and later studied law. He was returned to Parliament for Wallingford, Berkshire, in 1553, and in 1554 as member for both Reading, Berkshire, and Wootton-Bassett, Wiltshire; in 1554–55 he withdrew his company with 39 members who were dissatisfied with the proceedings of Parliament. Proceedings were brought against them for contempt. Plowden defended his own case, and the matter was dropped. He was returned to Parliament for Wootton-Bassett in 1555. After the accession of Elizabeth he received no further political recognition, his steadfast adherence to the Roman Catholic faith barring his path though he was admittedly the greatest lawyer of his day. No proceedings were taken against him, though he often appeared in court as counsel for those of his faith, Bishop Bonner being one of his clients. His works are highly valued as a clear and authoritative record of the law proceedings of his time. 'Les Commentaires' (1571) fully sustains his reputation as a great jurist, and he also wrote 'Les Quæres del Monsieur Plowden' (trans. 1662). Consult Granger, 'Biographical History of England' (1824); Wallace, 'The Reporters' (1882).

PLÜCKER, plük'ĕr, **Julius,** German mathematician and physicist: b. Elberfield, 16 July 1801; d. Bonn, 22 May 1868. He became a lecturer at Bonn in 1825, professor of mathematics there in 1829, and after holding a chair at Halle in 1834–36 was again at Bonn until his death. His contributions to mathematics were of much importance. He invented what is known as line (or linear) geometry, the theory of systems of rays, complexes and congruences, his uncompleted work on which was finished by Klein, his assistant, as 'Neue Geometrie des Raumes' (1868–69). In his 'Theorie der algebräischen Curven' (1839) he develops the «six equations,» known by his name, concerning the singularities of algebraic curves. From 1847 he devoted much attention to physics. He made study of the magnetic properties of gases and liquids, spectroscopy and electrical phenomena of light in rarified air. He originated the Geissler tubes and discovered the fluorescence of cathode-rays. His 'Analytisch-geometrische Entwickelungen' (1828–31) contains accounts of his labor in this field. Consult Dronke, 'Julius Plücker' (1871); Clebsch, 'Zum Gedächtniss an J. Plücker' (1872).

PLUM, the popular name for several species of the genus *Prunus,* extensively cultivated in mild climates for their fruits. They are widely distributed in the North Temperate zone, especially in America and eastern Asia. They have alternate, simple, leaves; white flowers mostly in cymes and generally appearing with the leaves; and drupaceous, one-seeded, bloom-covered fruits. They are closely related to apricots, cherries and peaches.

The most important species is the European plum (*Prunus domestica*), a native of the Caucasus region, and thought to have been derived from the blackthorn (*P. spinosa*). It has given rise to four distinct groups: *Prunes,* firm, thick-fleshed, sweet varieties of various colors (blues are best known), adapted for drying without the removal of the stone (see PRUNE); *Damsons,* little, firm-fleshed plums of diverse colors and usually clustered, frequent in fence corners; *Greengages,* small green, globular plums generally of high flavor; *Large,* yellow, blue, red and purple varieties. The domestics are the leading plums from New England southward to Pennsylvania, westward to Lake Michigan, and upon the Pacific Coast. Some of the hardier Russian varieties are being tried in the colder regions of the West and North.

Next in importance are the Japanese varieties of *Prunus triflora,* first introduced into America in 1870. This species is presumably a native of China. The fruits are generally rounder than those of the *domestica* varieties, and are more noted for their light reds and yellows. Their chief merits are: added variety to the list, especially of early maturing kinds, firm-fleshed fruits which ship well and vigorous, productive trees freer from the attacks of curculio and black knot (see below) than the *domesticas.* They succeed farther south than the *domesticas,* and in many instances farther north.

Several American species have also rapidly become popular in the United States and Canada. *Prunus americana* and *P. angustifolia* are the leading species, the former especially in the North and West, but also extending to the Gulf States; the latter popular from Pennsylvania southward. These are of still more recent introduction into cultivation than the Japanese varieties, and are valuable acquisitions where the two preceding groups fail. The wild goose plum is *P. hortulana.*

The following species are also cultivated: Myrobalan or cherry plum (*P. cerasifera*), presumably a Caucasian species, used largely by nurserymen for budding plums upon; apricot or Simon plum (*P. simonii*), an introduction from China popular in California since 1880, but little grown in the East; beach plum (*P. maritima*), common upon the coast from Nova Scotia to Virginia, but little cultivated except as an ornamental shrub; Pacific Coast plum (*P. subcordata*), indigenous in Oregon and California, and somewhat cultivated; and the sand plum (*P. angustifolia watsoni*), a shrubby species common in Kansas and Nebraska, but little cultivated.

Plums are propagated from seed only when new varieties are desired; varieties true to name are all propagated by budding or, to a very limited extent, by grafting. The process is the same as for the peach (q.v.). If *domestica* varieties are to be grown upon light soil they are generally whip-grafted on peach stocks, the peach being adapted to such soils. Similarly peaches to be grown upon heavy soil are often grafted upon plum stocks.

The various groups succeed upon a wide range of soil; the *domesticas* are generally well adapted to heavy soils; the Japanese to medium and even light; and the American kinds often to very light. There are, however, varieties in each group adapted to other soils than suit the majority. The land is deeply plowed and thoroughly harrowed before planting. The trees are set about 20 feet apart in squares or hexagons (see PEACH), or in rectangles from 8 to 12 feet asunder in rows 18 to 20 feet apart. In the last case cultivation is given only one way when the trees commence to touch. Usually less than half a dozen main limbs, preferably close to the ground, are allowed as the framework of the tree and after the first year or two little pruning beyond the removal of interfering, injured or dead branches is given. The trees are usually planted when two years old from the bud, extra vigorous growers sometimes when one year old. Varieties of the Japanese and American groups should not be planted in blocks of only one kind, since they are often self-sterile and fail to set fruit; two or more kinds should be alternated in the orchard. (See PEAR). Cultivation is practically the same as for apples and pears. In the Western States, however, a mulch of straw, marsh hay, etc., is often substituted for cultivation. The fertilizers usually employed are rich in potash and phosphoric acid. Cover crops of legumes should supply sufficient nitrogen, or a biennial dressing of stable manure may be used as a supplement. Occasional dressings of lime are often beneficial. Few fruits respond better to liberal feeding than the plum. The conservation of plant food which follows thinning the fruit, to stand at least two inches apart, is also of great benefit to both tree, annual productivity, size of fruit, and in the prevention of fruit rot. (See PEACH). When fully grown and colored but before becoming soft the fruits are gathered and generally marketed, in the East, in eight-pound Climax grape baskets. The plums shipped to eastern markets from California (mostly of the prune and Japanese types) are packed in boxes and sent by refrigerator express freight.

Some of the principal diseases of the plum are also common to the cherry or the peach, or both. Plum-pockets (*Exoascus pruni*) is a specific plum malady. Shortly after the blossoms fall the little plums swell rapidly to an inch long or more and become bladdery. As the disease progresses the light green color changes to deep brown or black, the walls thicken, the stone fails to develop and the fruit falls. Affected foliage and green twigs also become distorted. Spraying before the buds open and again after the flowers fall is recommended as a check. (See FUNGICIDE). Black, or plum-knot (*Plowrightia morbosa*) is common to both plums and cherries. Swellings appear upon the twigs and branches, burst and reveal a golden brown or yellow interior with velvety appearance due to the rapidly forming summer spores. As the season advances the surfaces change to black with a more or less pimply appearance. In the spring a second crop of spores (winter spores) is liberated. Under favorable conditions spores from either crop may spread the affection through crevices in the bark, etc. The knots are perennial, gradually extending the infested area. Cutting and burning as soon as discovered; painting the wounds with kerosene or Bordeaux mixture, thorough spraying with standard Bordeaux mixture before the buds open and with diluted mixture afterward are all recommended and should all be practised. One alone is insufficient. Badly infested trees

and trees of wild cherries, plums, etc., should be burned promptly. Leaf blight or shot-hole fungus is produced by two species of fungi, *Septoria cerasina* and *Cylindrosporium padi.* Small purplish spots upon the leaves gradually turn brown and drop out leaving shot-like holes. If badly infested the leaves turn yellow and fall, sometimes defoliating the trees. Spraying with diluted Bordeaux mixture at intervals of two weeks from the time the leaves expand until midsummer is considered a specific. This disease is often found on cherries. Systematic annual spraying will hold all these diseases in check.

Comparatively few insects feed upon the plum. Some caterpillars and other leaf-chewing insects sometimes appear in devastating numbers, but they can usually be controlled with Paris green (lime should be added to prevent injuring the foliage); plant lice are sometimes troublesome, but whale-oil soap, kerosene emulsion, etc., are effective. (See INSECTICIDE). But the most serious enemy is the plum curculio (*Conotrachelus nenuphar*), which in many sections has completely destroyed the crop. The adults, small gray-black snout beetles less than a quarter of an inch long, appear in spring and until the fruit has formed feed upon the foliage. Then the females chew little crescent-shaped cavities in the young plums, and lay their eggs in holes bored beside the crescent or in the crescent itself. The white, footless larvæ burrow to the region of the stone where they live for about three weeks. The fruits fail to develop and fall, and the larvæ burrow into the ground where they pupate for about four weeks, emerging as adults which hibernate. They have only one brood. Before the trees blossom arsenites may be used; but jarring the adults into sheets in the early morning while they are torpid and dropping them into kerosene is most practised. Special machines like inverted umbrellas on wheels are in use in large plum orchards. The plum gouger (*Coccotorus scutellaris*) is a troublesome pest in the Mississippi River basin. Its habits are much like those of the curculio. It does not, however, make a crescent-like mark, and its larvæ feed in the stone instead of around it.

PLUM CURCULIO. See PLUM.

PLUMAGE. Feathers are pre-eminently the distinguishing characteristic of birds: all birds have them, while no other animal possesses them. As elsewhere described (see ORNITHOLOGY) feathers fill two important functions, the retention of animal heat in the body and the support of the bird in flight; and since they cover practically the whole bird, all the striking features of color and ornament so highly developed in this group, pertain to the feathers.

The typical or pennaceous feather consists of a hollow nearly transparent, cylindrical portion (calamus), which merges above into an apaque, usually squared shaft (rhachis). The calamus, or quill, is composed of a series of oblong cells nesting into one another and containing the "pulp" from which the growing feather is built up. When the feather is complete these cells are empty. The shaft bears on either side the webs or vanes, soft flexible surfaces which upon slight tension split up into their component parts — rami or barbs. These are slender lamellæ which branch off from the rhachis and in turn give rise to branches — radii or barbules. The anterior barbules of one barb overlie the posterior barbules of the next barb and the numerous cilia (barbicels) which they bear, many of which are hook-shaped at the tip, interlock with the thickened upper edge of the posterior barbules, binding the barbs together and forming the substantial web which is so essential to flight. In the inner web of a crane's feather 15 inches in length have been counted 650 rami each bearing about 600 pairs of radii, or nearly 800,000 radii for the inner web alone and far above 1,000,000 for the entire feather. At the point where the rhachis emerges from the calamus is a pit known as the umbilicus and here is frequently found a sort of secondary feather known as the hyporhachis or aftershaft; it is usually much smaller than the main shaft and more downy in character, but sometimes, as in the emu, is of the same dimensions and appearance.

Feathers are entirely products of the skin, being similar to the scales of reptiles rather than to the fur of animals so clothed. They do not grow continuously, but are periodically shed and replaced by other feathers. The first feathers appear as small papillæ on the skin of the embryo. Each papilla is produced by a group of cells known as the Malpighian cells, which increase and divide, part of them growing down and forming the lining of the feather-follicle, the others forming the feather itself and surrounding the central mass or pulp, which is well supplied with blood-vessels and furnishes the requisite nourishment to the growing feather. The Malpighian cells which produce the feather form three layers — a thin exterior one, the sheath which covers the young feather in what is familiarly called the "pin feather" stage and later scales off as the feather expands; a middle layer, which forms the feather itself; and a very thin innermost layer, which covers the pulp and which persists inside of the calamus as a series of pithy caps left by the retreating pulp. This pulp is withdrawn to the base of the follicle when the feather is completely grown and becomes active again when the feather is shed, or at the time of the periodical molting (q.v.).

Feathers are classified into (1) contour feathers — those which are outermost and give

form to the bird; (2) down feathers,—the dense undercoating; (3) filo-plumes; and (4) powder-down feathers.

The first are usually pennaceous in structure, but in the various ornamental plumes, barbicels and even barbules may be wanting or reduced in number, producing a fluffy feather. The down feathers have no barbicels and usually no rhachis, but consist of long fluffy barbs, all of which grow out from the tip of a very short calamus. Filo-plumes are exampled by the long "hairs" found upon the body of the domestic fowl after the feathers have been plucked and commonly removed by singeing. They show under the microscope a degenerate feather structure of barbs and barbules. In the case of some birds, however, they become very long, reaching out beyond the contour feathers and influencing the coloration and texture. Powder-downs are down feathers which are constantly disintegrating into a fine powder and are found in the plumage of various birds, notably parrots, tinamous, herons and the species of *Podargus*.

With regard to age, feathers are divisible into two groups: (1) neossoptiles, or feathers of the young birds at the time of hatching; and (2) teleoptiles, or feathers of later life. The neossoptiles are of two kinds: (1) the prepennæ which immediately precede the contour feathers; and (2) the preplumulæ which precede the down feathers. A further division is made of the pre-pennæ into "protoptiles" and "mesoptiles," but these are important only to the scientific ornithologist. The neossoptiles are always downy in structure and after a varying period they are superseded by the teleoptiles. In the penguins there are two distinct plumages of neossoptiles one succeeding the other; the second growth beginning before the first is shed. The short calamus of the neossoptile never becomes closed up and is split longitudinally as it is forced out by the teleoptile and for some time its slender downy barbs are borne on the tip of the new feather. When one generation of teleoptiles succeeds another the old feathers usually drop out, but in the emus and cassowaries they remain attached to the tips of the new feathers, just as do the neossoptiles. Neossoptiles are best developed in the birds which run about within a short time after hatching, such as the gallinaceous birds, ducks, sandpipers, etc. In these species the body is thickly and completely covered with down. In the hawks and owls the covering is nearly as thick, but in the latter the neossoptiles grow out for a considerable time after hatching, sometimes completely altering the appearance of the bird. In the snowy owl, for instance, the newly hatched young with the tips of the neossoptiles showing, is pure white, while older ones, in which these feathers are full grown, appear dull gray, owing to the difference in color of the terminal and basal portions of the feathers.

In passerine birds the neossoptiles are not very abundant, while in several groups—notably the woodpeckers where the young are reared in hollowed trees and the kingfishers which burrow in sand banks — the neossoptiles have been entirely suppressed, so that the first coat of feathers on these birds consists of teleoptiles and the young birds are naked until these appear. This is perhaps owing to the protection afforded by the nest to the young, which renders the early downy covering less necessary. In the mound-builders a still more remarkable condition prevails. Here the neossoptiles are developed but are shed before the bird is hatched and it actually leaves the shell clad in the teleoptiles.

Feathers are not distributed uniformly over the body of a bird as are the hairs of a cat or rabbit, but they are in well-defined groups or areas known as "pterylæ," with bare spaces, "apteria" between. In some kinds of birds the apteria are covered with down feathers. The pterylæ are of characteristic outlines in different families and are thus of value in determining relationships.

It is obvious that the early plumage condition of birds is to some degree dependent upon their nesting habits and this must be clearly borne in mind when it is considered in connection with classification. Thus many apparently striking characters will be seen at once to have been very recently acquired.

Following the nestling stage, birds acquire one coat of feathers after another, the frequency of the change depending upon the number of molts. The first teleoptile or "juvenal" plumage is generally quite different from that of the adult, is worn for only a few months after the bird leaves the nest, when it is superseded by the plumage of the first winter, in which the characters of the adult generally appear. This may be retained for a whole year, or it may give way to a nuptial plumage in the early spring, the latter being always the case in birds which are strikingly different in color in summer and winter. It is now demonstrated that feathers cannot change their pigment after they are once developed and consequently striking changes are due to molt. There are some partial exceptions to this, in the case of birds whose plumage undergoes marked wear or abrasion, such as the snow-bunting. In this species the feathers of the back are black at the base, those of the head white, but both are broadly tipped with brown, and as they lie in place brown is the prevailing tint. In early spring the tips become brittle and fall away, leaving the black-and-white basal portions in strong contrast. In the crossbill, as shown by Dr. Dwight, the barbs are red and the barbules gray and in spring the latter fall off, resulting in a material brightening of the plumage.

The relation of the juvenal plumage to that of the adult bird is a matter of much interest, owing to the fact that it usually shows some ancestral characters, and often gives us a clue to the relationship of the species; for example, the young of our robin is spotted like the ancestral thrushes, while the adult has departed widely from this type in its plain rufous breast and slaty back.

In a large number of species the plumages of the male and female differ materially; the latter is always the more primitive, and the male generally assumes a dress similar to it for the winter, returning to his brilliant livery on the approach of the nuptial season. Darwin's theory of sexual selection, which was formerly held to account for the brilliant plumage and wonderful ornamental feathers of male birds is in the light of modern investigations not satisfactory, but no acceptable theory has yet been presented. Protective coloration in plumages has received a good deal of attention from

Wallace and others, and doubtless the theory in some cases has been unduly elaborated. While protective coloration plays a part in the evolution of plumage it is quite as likely that, for instance, pale desert forms are as much the result of the direct effect of the sun as purely protective development. The protective plumages of the ptarmigan both in winter and summer, and the curious protective or "eclipse" dress acquired by certain ducks in summer when rendered temporarily flightless by their peculiar method of molting, deserve mention in this connection.

Molt varies in extent, may be complete or only partial. That which takes place after the breeding season is always complete; but the spring molt may be complete or reduced to a few feathers only, varying greatly. Molting takes place after a definite plan which differs with the species. In ducks, and certain other water birds, the quills are shed all at once. See PTERYLOGRAPHY. Consult Chapman, F. M., 'Handbook of Birds of Eastern North America' (Rev. ed., 1912; pp. 84–96); Dwight, J., 'Sequence of Plumages and Moults of the Passerine Birds of New York' (in Annals of the New York Academy of Science, Vol. XIII, pp. 73–360, New York 1900); Stone, W., 'The Molting of Birds' (in *Proceedings* of the Philadelphia Academy of Natural Sciences, 1896; pp. 108–167); Strong, R. M., 'The Development of Color in the Definitive Feather' (in Bulletin of the Museum of Comparative Zoology of Harvard College, Vol. XL, No. 3; Cambridge 1902).

PLUMB-LINE. See PLUMMET.

PLUMBAGO, a genus of herbs or subshrubs of the order *Plumbaginaceæ;* the leadworts. The species, of which about a dozen are known, are natives of warm climates, especially western Asia and the Mediterranean region. They have variously formed, usually alternate, entire leaves; and white, pink or blue tubular flowers, arranged in terminal spikes or racemes. The best-known species are *P. capensis* and *P. rosea,* which are popular as greenhouse and garden plants. They are easily propagated by cuttings, and will thrive in any good potting or garden soil. In cold temperate climates cuttings rooted in the early autumn, grown in the greenhouse during the winter, and transplanted to the garden in the spring, will blossom through the summer and autumn and may then be used as winter plants or kept in a cellar. In southern California and other mild climates the plants often climb 15 feet or more if not molested, but in greenhouses they are usually straggling shrubs.

PLUMBAGO, or **GRAPHITE,** also called black lead. See GRAPHITE.

PLUMBING AND STEAM FITTING. The word "plumbing," derived from the Latin *plumbum* (lead), as originally used, meant to seal or repair with this metal, but the term as now used, in its broadest sense, means the pipes, connections, fixtures, etc., used for the purpose of supplying water, gas, hot water, steam or hot air from outside places to the interior of a building, or of carrying these throughout the building; and also for the purpose of drainage. All the ancient nations employed lead pipes to some extent; water was universally conveyed through them when the pressure was too great for earthenware pipes; and the Romans used them in their aqueducts in crossing ravines or valleys where the construction of bridgework was difficult or impossible.

The improvement in plumbing fixtures was remarkably slow, and has taken place within the last 100 years. The trade of plumbing was practically unknown prior to that time, but upon the completion of the Croton Aqueduct in 1842, more substantial and durable pipes and fittings became necessary, a condition which ultimately led to the establishment of manufactories of plumbers' supplies. At first these concerns were engaged almost exclusively in the manufacture of lead pipe, sheet lead or iron pipe, which were the principal articles used by the plumber, but to-day lead has been largely replaced by other metals, and we find that the plumber and the gas, steam and water fitter use lead, copper, brass and various styles of plated pipe, and that the use of vitrified clay or sewer pipe has been almost entirely abandoned, except for connecting the house and street sewerage systems. The grade of work done by the plumber has made a very material advance, the work being done largely by licensed plumbers, and in many cases under the direct supervision of expert inspectors employed by the city. In nearly all large cities plumbing is governed by rules and regulations, carried into effect by the department of the city government appointed for that purpose, and it is the duty of such departments to enforce the regulations which define the class of work to be done, the sizes of the various kinds of pipes to be used, the class of fixtures, etc. Such work usually comes under the supervision of the building, or the sewerage and water supply departments. The service pipe, which connects the system of supply pipes in a building with the main in the street, is generally laid by the water department.

For many years the entire plumbing system of the ordinary dwelling consisted of a sink with hot and cold water faucets over it, and connected with the water-back and boiler attachments of the range. This was followed by the installation of the bath-tub — an unsightly affair, consisting of a wooden box lined with lead. This was in time replaced by the cast-iron tub, then the copper-lined tub, both of which were superseded by the modern porcelain bath-tub, which is of cast-iron with a porcelain finish. The fixtures supplied by the plumbing trade are almost innumerable. Faucets, cocks and valves are provided for each place where water is drawn; laundry tubs, provided with hot and cold water pipes, are installed in the kitchen; marble, cast-iron or steel wash bowls are placed in the bathrooms or sleeping-rooms of a dwelling; and shower and foot-baths are provided when desired.

The main feature of the plumbing in a modern dwelling lies in the water-closet and the system of pipes which carry off fouled water. In this division of plumbing more care and ingenuity have to be exercised by the plumber than in any other line of the trade, for it is with this division more than any other that the question of general public health is concerned. Hence this branch of work is often called

sanitary plumbing. Sewage is a constant menace to health and it is the carrying off of refuse upon which the manufacturers have turned their inventive facilities. Though water-closets have been in use as long as have bath-tubs no special attention was paid to their improvement in construction till 1775, when the first patent was taken out in England by a watchmaker, named Alexander Cummings. This was of the siphon-trap style, and in 1778 was followed by a closet with a valve which worked on a hinge at the bottom of the bowl, the invention of Joseph Bramah. In 1792 another patent was granted for a valve closet supplied with a tank, the hopper of which was flushed by pressure on the seat. From that time the inventions were many and various, until at the present time we have valve closets, pan closets, plunger closets, hopper closets, cistern closets, siphon closets and latrines. The old-fashioned pan closet, used almost universally many years ago, was one of the most unsanitary of all the plumbing fixtures in use, and because of its filth and stench has been generally discarded. It consisted of a metal pan which worked on hinges, and when let down emptied the contents into the discharge pipes. Then came the valve and plunger closets, which were later superseded by the siphon closets. The valve closet takes its water from the main service pipe, whereas the cistern closet receives its supply of water in the tank from the main, and it is then discharged in the bowl by pulling a hanging chain attached to a lever, which raises the valve in the cistern.

Water-closets are now most generally constructed of glazed earthenware, some are made of the finest bona china and others again are made of cast-iron with a china finish. The old-styled closed plumbing has given way to the most modern sanitary appliances, and open work is generally to be found even in the poorest dwellings, because of its cleanliness, healthfulness and ease of access to repair.

The next part of the general sanitary system to be considered is the arrangement of pipes and appliances which connect the basins, sinks and water-closets with the general sewer. Ventilation is one of the most important subjects which the sanitary plumber must understand. How to prevent gases arising from sewers — for where there are sewers there is sure to be sewer-gas — and how to prevent the air in a room from becoming foul, have been constant sources of trouble to the modern sanitary plumber, and that he has solved these problems has probably resulted in more benefit and insured the public against more harm from diseases attendant upon these evils than any other one thing. It is an indisputable fact that the wise and exact observance of these sanitary laws has been a potent factor in materially reducing the death rate in our larger cities.

In this system of pipes the most important object is to prevent the air within them from gaining access to the building. This is most generally done by means of a trap or depression in the pipe, or by making the internal pipes gas-tight. The inverted siphon, sealed by water lying in the bend, is probably the best form of trap. Fresh air should have free access to the pipes, the air of the sewer should be shut off from that of the pipes within the house and fouled water should be immediately and completely removed from the vicinity of the building. The ventilation largely affects the methods of connecting the main drain with the soil-pipes. The most general and easiest method of ventilating the soil-pipes is to extend the drain pipe to a point above the roof, and through this the current of air, which comes in at the manholes in the street and passes along the street sewers, flows upward and out. The method is most effective where the street sewers are constructed on the "separate" system, but where the street sewers are built on the "combined" plan, it is preferable to have a trap on the house sewer in connection with the fresh air inlet, because of the fact that the foul-air currents are thus diverted from the interior pipes and a current of fresh air is forced upward through the soil and ventilating pipe.

Waste pipes should be of lead, though sometimes cast or wrought-iron is preferable because of the large diameter required and the soil; waste and ventilating pipes should be exposed as much as possible for purposes of inspection or repair. The main house drain and the soil pipe should be of heavy cast-iron with lead-calked joints, and all iron pipes and fittings should be coated with coal-pitch varnish, both inside and outside. If plumbing work be carried out on the ideas set forth, with proper traps, light, ventilation, simplicity, accessibility, good workmanship and a high grade of material throughout the public health will properly be insured against the ravages of disease so common before the improved appliances came into vogue.

Another distinct division of the plumbing trade is the carrying of steam in pipes throughout a building. Prior to 1840 and even as late as the Civil War, the growth of steam heating had not assumed any great proportions. English inventors had made many attempts at steam heating by means of small pipes connected with boilers, on the theory that this would create a high temperature. But this soon gave way to the low pressure system because of the fact that there was little or no wear upon the apparatus, and the generation of the low pressure saved fuel. Joseph Nason, of New York, and J. J. Walworth, of Boston, were largely instrumental in the earlier development of the industry. Boilers were first used, but these were quickly followed by radiators constructed of wrought-iron tubes, both vertical and horizontal. In 1865 the manufacturers began to make heating boilers and radiators from cast-iron, and the manufacture of steam and hot-water furnaces has become an industry of great importance. The development of the modern office building has in a large measure added to the success of this branch of the trade, for it is in these that this system of heating is carried to its greatest degree of perfection. The boilers used in these buildings are of wrought-iron or steel, because the running of elevators, electric lights and pumps, necessitates that a high pressure be maintained on the boiler.

The industry is now so complex, drawing its supplies from several lines of manufacture, and consisting mainly of contracting work, that accurate statistics of its extent cannot be compiled. Consult Hall, H. T., 'Practical Plumbing' (Chicago 1937); and Johnson, J.

W., 'New Handy Manual on Plumbing, etc.' (13th ed. 1925); Warren, G. M., 'Simple Plumbing Repairs' (Washington 1925). See BOILER; BATH; DRAINAGE; PUBLIC HEALTH; SANITARY ENGINEERING; SANITARY SCIENCE; VALVES; WATER SUPPLY; etc.

PLUMBOJAROSITE, a lead ore consisting of a hydrous sulphate with iron, $PbFe_6(OH)_{12}(SO_4)_4$, occurring in mines in Colorado, Nevada, New Mexico and Utah.

PLUME-MOTH, or **FEATHERWING,** one of the small moths of the family *Pterophoridæ,* allied to the clothes-moths, which are readily distinguished from all others by the fact that their wings are deeply cleft at the edges, so as to resemble five (sometimes six) feathers on each side of the body. Some 70 species have been enumerated. The grapevine plume-moth (*Oxyptilus periscelidactylus*) as larvæ leaves silk-like strands on the leaves of the grapevine. The caterpillars have 16 legs and develop to pupæ in the early summer. As moths they have slim bodies and are of various colors. The *Ooneodidæ,* having six side feathers, are also classed as plume-moths.

PLUMED KNIGHT, The, a name applied to James G. Blaine (q.v.). It was first used in a speech made by Col. Robert G. Ingersoll, when nominating Mr. Blaine for the Presidency in 1876.

PLUMIER, plü-mē-ā, **Charles,** French botanist: b. Marseilles, France, 1646; d. Santa Maria, near Cadiz, Spain, 1704. He studied under Joseph de Tournefort, and in 1689 went to the West Indies, engaged in botanical researches under the government and on his return published 'Description des Plantes de l'Amérique' (1693). Subsequently in 1693 and 1695 he made voyages to America at the request of the king, and he was about to sail on a fourth voyage when he died. His 'Traité des Fougères de l'Amèriques' (1705) is still an authority; among his other works are many valuable manuscripts in the library of Paris and in the Jardin des Plantes, and 'Nova Plantarum Americanarum Genera' (1703). Consult Haller, 'Bibliotheca Botanica.'

PLUMMER, Alfred, English Biblical scholar: b. Heworth, Durham, 17 Feb. 1841; d. Devonshire, 19 April 1926. Educated at Exeter College, Oxford; Fellow of Trinity College in 1865–75; tutor and dean in 1867–74; and master of University College, Durham, from 1874 to 1902. He published translations of several of Dr. Döllinger's works (1870–75); commentaries on II Saint Peter and Saint Jude (1879); 'Saint John's Gospel and Epistles' (1880–86); 'The Pastoral Epistles' (1889); 'Epistles of Saint James and Saint Jude' (1890); 'Introduction to Joshua and Nehemiah' (1881); Handbook on the Church of the Early Fathers' (1887); 'Commentary on Saint Luke's Gospel' (1896); 'Second Corinthians' (1903; enlarged ed., 1914); 'Saint Matthew' (1909); 'Saint Mark' (1914); 'Lectures on English Church History, 1575–1649' (1904); 'Lectures on English Church History, 1509–1575' (1905); 'Lectures on English Church History, 1649–1702' (1906); 'The Church of England in the 18th Century' (1910); 'The Churches in Britain before A.D. 1000' (1911); 'The Humanity of Christ and Other Sermons' (1913); 'Continental Reformation in Germany, France and Switzerland' (1912); 'Philippians' (1919), etc.

PLUMMER, Mary Wright, American librarian: b. Richmond, Ind., 1856; d. 21 Sept. 1916. She was educated at Wellesley and at Columbia University, was librarian of the Pratt Institute Free Library, Brooklyn, in 1896–1904, also director of the Library School there from 1896 to 1911. After 1911 she was principal of the Library School of the New York Public Library. Miss Plummer was president of the American Library Association in 1915. Her publications include: 'Verses' (1896); 'Hints to Small Libraries' (1911); 'The Seven Joys of Reading' (1916); 'Training for Librarianship' (1923). A symposium in her honor was printed in the New York *Library Journal* in 1916, following her death.

PLUMMET, or **PLUMB-LINE,** a leaden or other weight let down at the end of a cord to regulate any work in a line perpendicular to the horizon, or to sound the depth of anything. Masons, carpenters, etc., use a plumb-line fastened on a narrow board or plate of brass or iron to judge whether walls or other objects be perfectly perpendicular, or *plumb* as the artificers call it. Near a range of high mountains the plumb-line, as has been demonstrated by a number of experiments, is not perfectly true, but inclines toward the mountains; and officers in charge of the United States Coast and Geodetic Survey among the Hawaiian Islands have observed that the deviation of a plumb-line from the vertical is greater in the case of mountains in an island than in continental mountains, and greater in the neighborhood of extinct volcanoes than in that of active volcanoes. In given localities the plumb-line also varies according to the ebb and flow of the tide.

PLUMPTRE, plŭmp'tr, **Edward Hayes,** English theologian and scholar: b. London, 6 Aug. 1821; d. Tunbridge Wells, 1 Feb. 1891. He was educated at Oxford, and was successively chaplain at King's College, London (1847), professor of pastoral theology there (1853), and professor of exegesis there in 1864. He was also appointed prebendary of Saint Paul's, London (1863), rector of Pluckley, Kent (1869), and vicar of Bickley, Kent, in 1873. In 1869–74 he was one of the revisers of the Old Testament and was appointed dean of Wells in 1881, a position which he held until his death. Among his published works are 'Lazarus and Other Poems (1864); 'Master and Scholar,' verse (1866); 'Christ and Christendom' (1867); an excellent verse translation of Sophocles (1865), and a similar one of Æschylus (1868); 'Biblical Studies' (1870); 'The Law of Progress in Theology' (1876); 'Saint Paul in Asia' (1877); 'Movements in Religious Thought: Romanism, Protestantism, Agnosticism' (1879); 'Theology and Life' (1884); 'Things New and Old,' verse (1884); 'The Spirits in Prison' (1884); a verse translation of the Commedia and Canzoniere of Dante (1886–87); 'Wells Cathedral and its Deans' (1888); 'Life of Bishop Thomas Ken' (1888).

PLUNKET, William Conyngham, 1st BARON PLUNKETT, British statesman: b. Enniskillen, Ireland, 1 July 1764; d. Old Connaught Wicklow, Ireland, 4 Jan. 1854. He was gradu-

ated from Dublin University in 1784, admitted to the bar in 1787 and in 1797 became king's counsel. In 1789–1800 he sat for Charlemont in the Irish Parliament and acquitted himself with much credit until the extinction of that body. He was appointed solicitor-general in 1803 and appeared for the prosecution at the trial of Robert Emmet; in 1805 he was appointed attorney-general for Ireland and in 1807 and 1812–22 sat in the British House of Commons, where as a Protestant he made a resolute fight for Catholic emancipation. In 1822 he was raised to the peerage, was attorney-general of Ireland 1822–27, chief justice in 1827–30 and Lord Chancellor from 1830–41, when he retired from public life. Consult Plunket, David, 'Life, Letters and Speeches of William Conyngham Plunket' (1867).

PLUNKETT, Horace Curzon, Sir, Irish statesman: b. in Ireland 1854. He graduated from Oxford, and came to America, in 1879. After 10 years in Montana, he returned to the old soil, and soon became active in politics. He adopted the interests of the farmers, and in 1894 founded the Irish Agricultural Organization. He had in 1892 gone into Parliament as a Unionist. He advocated discussion and harmony, and urged a "Recess Committee" to work on these lines. He was made chairman, and had on his committee Earl Mayo, John Redmond, The O'Conor Don and Thomas Sinclair. Thereupon Plunkett worked up a long report in the systems of agricultural aid extended in other countries, and his committee backed it. The result was the act of 1899 establishing a Department of Agriculture in Ireland, with Plunkett as vice-president. He remained in the office even under the Liberal opposition until 1907 when he was pushed aside by politics. In 1903 he was knighted; in 1911 he was returned to office; in 1914 was active in effort to pacify Ulster; chairman, Irish Convention, 1917–18; Senator in the Irish Free State Congress, 1922–23. He published 'Ireland in the New Century' (1904); 'The Rural Life Problem in the United States' (1910); 'Some Tendencies of Modern Medicine' (1913); 'A Better Way: An Appeal to Ulster' (1914). D. 26 March 1932.

PLURALISM. A term denoting that view of the world as composed of a number of independent beings, and thus opposed to Monism (q.v.), which asserts that there is only one ultimate form of reality (as for example, with Spinoza, who regards all finite things as modes or manifestations of one substance, or with the idealism of the present day which interprets all forms of existence as parts of an Absolute Experience). In some sense both Monism and Pluralism must be true; that is, in some sense the world is one, a single universe, and in some sense it is composed of many various parts. The ultimate problem of philosophy is to define the sense in which each of these propositions is true, to reconcile the point of view of the one with that of the many.

The practical motive in the opposition between Monism and Pluralism lies chiefly in the necessary implications of these theories regarding the place and importance of the human individual in the world. Pluralism is a protest against a Monism that would merge the many individuals in a one all-embracing, absolute system, and thus leave no place for their independent life and power of free initiative. Against the "block world" of Monism, the Pluralists insist on the separateness and uniqueness of the personal life of the human individual, which cannot be reduced to a mere part or element in a larger whole. On the other hand, the Monists point out that through over-emphasizing the independence and separateness of individuals, the Pluralists are unable to reach any intelligible conception of a system or universe of things, or to discover any common standard of truth or of conduct.

J. E. Creighton,
Late Professor of Logic and Metaphysics, Cornell University.

PLURALISM, *in canon law,* the holding by the same person of more than one ecclesiastical office of dignity or emolument. From early times it has been legislated against by various councils, but it is now very rare in the Catholic Church. In the Anglican Commission it is regulated by the Pluralities Act of 1838, as amended in 1850. Consult the 'Catholic Encyclopedia' (15 vols., New York 1905–15).

PLURALITY, (1) in ecclesiastical law, the holding of more than one office by the same person; also, one of the offices so held. (2) The greatest of three or more numbers; also, the excess of the highest number over the next highest. In this sense, the word is commonly used in elections in the United States when one candidate has received more votes than any one of two or more opponents. Thus, if one candidate receives 40,000 votes, a second 35,000 votes and a third 25,000 votes out of a total of 100,000 votes cast, the first is declared elected by a plurality of 5,000 votes.

PLUSH, a textile fabric, usually of wool, cotton or silk, having a cut pile on one side, distinguished from velvet in that the pile is longer. A well-made plush is costly but beautiful and may be produced to closely imitate seal-skin. It has become common to weave silk plush on a cotton foundation.

PLUTARCH, ploo'tärk (Gr. Πλούταρχος), Greek writer: b. Chæronea, Bœotia, about 46 A.D.; d. there, about 125. He studied philosophy under Ammonius, a peripatetic philosopher of Attica, in 60 A.D., which is the only indication of his age. He several times visited Rome, where during the reign of Vespasian he remained for some little time, giving lectures in philosophy and collecting materials for his 'Lives.' He spent his later years at Chæronea, where he had a priesthood and was also an archon and building-inspector. To many friends he was guide, philosopher and mentor, expounding especially the tenets of the Greek moralists then very popular among men of culture. A school or group gathered about him to which he lectured on Greek and Roman institutions. He was a great admirer of the Spartans, but appears not to have been fully conversant with Roman institutions. His 'Parallel Lives of Illustrious Greeks and Romans' is the work to which he owes his fame. The lives are written in pairs, one Greek and one Roman, followed by a comparison of the two, which in some instances is wanting. A few of the 'Lives' themselves are lost. In these 'Lives' Plutarch is said to have quoted 250 authors, the works of many of whom are lost. The work is chiefly intended for the illustration of char-

acter, and as he makes use of incidents for this purpose without regard to their relative value, is only partially serviceable for historical purposes. In the arrangement of his incidents he does not always follow a chronological order. Their excellence consists mainly in their fidelity in biographical portraiture. They traverse all of the classical antiquity, are the prime authority, and the only one, for numberless factors, and contribute more, perhaps, along certain lines to the knowledge of the ancient world than does any other one work. A knowledge of them was long considered indispensable to culture. A Latin collection, consisting of translations made by different persons of the separate lives, was printed in Rome in two volumes folio in 1470. The first edition of the text was printed in Florence in 1517. An edition by Bryan, with Latin translation (completed after his death by Du Soul), was published in 1729. There are editions by Coraes (1809–15), Sintenis (1839–46), and Dübner (1846–47). Among translations there is the fine French translation by Amyot (1559), and there is of this the worthy English version by Sir Thomas North (1579), characterized as "Shakespeare's storehouse of learned history," since to it the great dramatist was indebted for his outlook on classical history and some of his finest characters and plots, as also one by Evelyn, Garth, Creech and others, with a life by Dryden (1638–86); and one by John and William Langhorne (1770, with several subsequent improved editions). The translation called Dryden's was corrected and revised by A. H. Clough, and published in 1859. George Long has translated and annotated some of the 'Lives.' Plutarch's other works, about 60 in number, are generally classed as 'Moralia,' though some of them are narrative. The style of some is difficult while the genuineness of others is open to question. They include 'On the Education of Children,' in which some sterling maxims are propounded for the guidance of parents, who, according to Plutarch, should be of equal rank; 'How a Young Man Ought to Hear Poetry,' containing very many quotations from Homer and the tragedians; 'On the Right Way of Hearing,' in which the value of silence is emphasized, caution not to give too great weight to a speaker's style and diction, and a generous appreciation advocated; 'How a Flatterer may be Distinguished from a Friend,' evidently the world of Plutarch's day suffered more from flatterers than we do today; the work abounds in quotations; 'How One May be Conscious of Progress in Goodness,' in which are given various criteria by which our moral progress may be measured; 'How to Get Benefit out of Enemies' advises turning our enemies to some good purpose for ourselves either by inducing in us an honest life so that they may be made jealous of us, or by their criticisms pointing out the way we must travel toward perfection, etc.; 'On Having Many Friends'; 'On Chance'; 'On Virtue and Vice,' all three containing numerous citations, otherwise unknown to us; 'Precepts About Health' is strewn with many platitudes enunciated in technical and difficult idiom; 'Advice to the Married,' containing short precepts and anecdotes and a few citations; 'The Banquet of the Seven Wise Men,' a treatise in narrative form of what happened at a public gathering near Cornith; 'On Superstition,' containing numerous quotations and many excellent maxims applicable even in our day; it is one of the most interesting of the 'Moralia'; 'On Isis and Osiris,' a treatise on Egyptian symbolism of great interest to Egyptologists; 'On the Cessation of Oracles,' a discussion of the decline in popularity of the old Greek seats of worship and prophecy; 'On the Face of the Moon's Disk'; 'On Fate'; 'On the Genius of Socrates'; 'On Exile'; 'Consolation to His Wife,' a feeling exhortation to a grief-stricken mother; 'Short Sayings'; 'Parallels,' etc. Philemon Holland executed an English translation of the 'Morals' (1603), and there is also a translation revised by W. W. Goodwin (1874–78). An edition of all the works of Plutarch, by J. C. Hutten, appeared at Tübingen (1791–1805). There is also a Paris edition with Latin translation (1862–77). The latest English translation is by Clough, A. H. (5 vols., New York 1909). The best text of the 'Moralia' is that of Bernardakis (1888–97). The name Plutarch is sometimes given to a collection of lives of distinguished men. Consult also Volkmann, 'Leben, Schriften, und Philosophie des Plutarch' (Berlin 1873); Oakesmith, John, 'The Religion of Plutarch' (New York 1903); Gréard, 'De la morale de Plutarque' (Paris 1866); Trench, R. C., 'A Popular Introduction to Plutarch' (London 1873); Wright, W. C., 'A Short History of Great Literature' (New York 1907). See PLUTARCH'S LIVES, NORTH'S TRANSLATION OF.

PLUTARCH'S LIVES, North's Translation of. Sir Thomas North was a soldier and public official rather than a man of letters, but he shared with other Elizabethans that striking versatility which enabled so many of them to attain distinction in more than one field of activity. His literary works were all translations, the most important being his Plutarch. Various other translations of the 'Lives of the Ancient Grecians and Romans' have appeared since North's, but none has supplanted his in interest for the general reader. The scholar will not be satisfied by North's version, for North translated not from the Greek original, but from the French version of Bishop Amyot. His purpose was not to produce a literally faithful translation, but one which would put the spirit of Plutarch into an Elizabethan body. His ulterior aim was to provide a series of "noble men's lives" which should serve as models of conduct to his own contemporaries, for he thought wisdom might be acquired better in this way than by reading about it "in philosophers' writings." His knowledge of men and affairs made him peculiarly appreciative of the elements of character, and none of the flavor of Plutarch's Grecians and Romans has evaporated in their transition through French into English. Amyot's French version, though fairly close to the original, was written in a somewhat formal, Ciceronian style, but North chose to write in a more familiar and realistically contemporary manner. His style is, therefore, more pointed, more concrete and picturesque than either the Greek of Plutarch or the French of Amyot. By means of a word or synonym added here and there, by phrases slightly altered, he increased greatly the vividness of the narrative. Where Amyot

was dignified, North frequently substituted homely and familiar images and phrasing. Thus where Amyot translates «Ne s'etoit jamais party de sa maison,» North gives a more concrete turn to the passage in his «never went from the smoke of his chimney.» An infinitude of slight variations of this kind makes of North's Plutarch a much more lively, more intimate and entertaining work than the French version upon which it was based. In the end they constitute rather an interpretation than a translation of Plutarch. The supreme test of North's ability to seize upon and express vividly the essentials of a character is to be found in the fact that Shakespeare in his Roman plays frequently took over bodily North's phrasing, often with only such slight modifications in word order as were necessary to change North's prose into blank verse.

GEORGE PHILIP KRAPP.

PLUTEUS. See LARVA.

PLUTO, ploo'tō, in Greek mythology, the giver of wealth, or Hades, the god of the lower world. He was depicted as the third son of Cronus (Saturn) and Rhea, a brother of Zeus (Jupiter) and Poseidon (Neptune). He is represented as judging every open and secret deed, sitting in gloomy majesty, his forehead shaded with hair, and wearing a thick beard. His head is sometimes covered with a veil. He frequently also wears his helmet, or a crown of ebony, or a wreath of adiantum or narcissus. In his hand he holds a two-forked sceptre, a staff, or a key; and by his side is Cerberus. He is seated either on a throne of ebony or in a chariot. The cypress, the box, the narcissus, and the fern adiantum (maiden-hair) were sacred to him; oxen and goats were sacrificed to him in the shades of night; and his priests were crowned with cypress. Since he did not heed sacrifice or prayer he was worshipped only on rare occasions. The Romans identified him partly with Orcus, partly with Dis. Consult Gayley, C. M., 'Classic Myths in English Literature and Art' (Boston 1911). See PERSEPHONE.

PLUTO, ninth planet of the solar system, whose discovery was announced 13 March 1930 by the Lowell Observatory, Flagstaff, Arizona, was found as the direct result of a specific search begun by Dr. Lowell in 1905. The presence of the planet was first noted on photographic search plates on 21, 23 and 29 January 1930, and, being then recognized, its course was followed closely upon numerous plates up to the time of announcement. In brightness the planet appeared of the 15th magnitude, and apparently of a yellowish tint—in contrast with the blue tint of both Neptune and Uranus. Pluto appears to be about 8,000 miles in diameter, revolving on its axis at a peripheral speed of between one and two miles per second, and completing its orbit around the sun in about 300 earth years.

PLUTONIC ROCKS, those igneous rocks which were formed at great depths beneath the surface of the earth, under pressure, and have later been forced toward the surface. They have usually a distinctly crystalline structure, due to their having cooled slowly, and are contrasted with volcanic rocks which, while also of igneous origin, have been poured out at or near the surface of the earth and have solidified there. The granites are the chief of the plutonic rocks.

PLUTUS, ploo'tŭs, Greek god of wealth, son of Iasion and Demeter. He was blinded by Zeus in order that he might not confer riches on the good alone. In Greek statuary he is represented as a boy with a cornucopia symbolically indicating that through agriculture comes wealth. His residence is beneath the ground and this has sometimes confused his identity with that of Pluto. He comes to mortals weak and lame, but departs from them with winged feet.

PLUVIOSE, plü-vē-ōz, in French chronology, the name adopted, in October 1793, by the French Convention for the fifth month of the republican year. It commenced on 20 January and was the second winter month.

PLYMLEY, plĭm'lĭ, **Peter,** pseudonym of Sydney Smith (q.v.). In 1807–08 he published 'Letters on the Subject of the Catholics to my Brother Abraham by Peter Plymley,' which enjoyed a wide circulation and greatly furthered the cause of Catholic emancipation.

PLYMOUTH, Conn., town in Litchfield County; alt. 700 feet; 10m. N. of Waterbury. Eli Terry, pioneer clock-maker, 1771–1852, set up America's first clock factory here, in 1807. Pop. (1940) 6,043.

PLYMOUTH, England, an important seaport and commercial town of Devonshire, on Plymouth Sound, between the estuaries of the Plym and Tamar, 36 miles southwest of Exeter. Devonport on the west, Stonehouse in the middle, and Plymouth proper on the east, constitute the aggregate known as «The Three Towns.» The area of Plymouth proper is four square miles; of the three towns eight square miles. Devonport has on the west the Hamoaze or lower part of the Tamar estuary, and is divided from Stonehouse and Plymouth proper by an inlet crossed by several bridges. (See STONEHOUSE and DEVONPORT). Plymouth extends from Stonehouse on the west to the Plym or Catwater on the east. The site is uneven, consisting of a central hollow and two considerable eminences, one on the north, and the other, called the Hoe, on the south, laid out as a promenade and recreation ground, from which a magnificent view is obtained. On the Hoe has been re-erected (Smeaton's) old Eddystone lighthouse, and there are also here a statue of Sir Francis Drake, and a memorial of the Armada. At the east end of the Hoe, on a bold headland, stands the citadel erected in the time of Charles II. The older parts of the town consist of narrow and irregular streets, devoid of architectural beauty, and often steep and winding. But in the newer parts and suburbs many handsome terraces and villas have been erected. The public buildings include the guildhall, a handsome Gothic building; the Royal Hotel and theatre, in the Grecian style; the post office; the custom-house, the exchange, the Athenæum, the Mechanics' Institute, the Plymouth and Cottonian public library, containing 10,000 volumes, and a collection of original drawings, prints, paintings and artistic articles, the grammar and other endowed schools, the Public Dispensary, Female Penitentiary, Eye Infirmary, South Devon and East Cornwall Hospital, etc. The laboratory and headquarters of the Marine Biological Association are located here. Among ecclesiastical buildings are the two parish churches, Saint Andrew's Church, a fine Gothic

building of the 15th century containing some fine monuments, and Charles' Church, of the 17th century, with an elegant spire; Sherwell Congregational Chapel and the Roman Catholic Cathedral.

The manufactures include soap, sail-cloth, brushes, Roman cement, earthenware, rope and twine, etc., and there are also ship-building yards, foundries, two sugar refineries, breweries, starch-works and flax, saw and flour mills, together with limestone quarries. The fisheries, chiefly of whiting, hake and mackerel, are very productive. The trade also, both coasting and foreign, is very important. Steamers ply regularly to North America, the Cape, Australia, New Zealand, the West Indies, etc. The parts of the port chiefly appropriated for mercantile shipping are Sutton Pool and Mill Bay, particularly the latter, where there are extensive wet-docks, and the largest vessels lie in safety along its fine pier and pontoon at low water.

Plymouth owes its celebrity chiefly to its importance as a great royal naval station, for which the spaciousness of its sound renders it admirably suited. It was the scene of immense activities during the World War. Originally, however, the sound, about three miles wide at its mouth, being open to the southwest winds, left vessels at anchor exposed to the greatest danger. With the view of protecting the anchorage from the heavy swell of the sea, the stupendous Plymouth breakwater was undertaken, and finally completed at an expense of about $10,000,000. On the west end of the breakwater a lighthouse, 68 feet above the platform, and visible at the distance of eight miles, except in foggy weather, has been erected, but the entrance into the sound is guided by the still more celebrated Eddystone lighthouse, which stands on a large cluster of rocks in the channel opposite to it. To defend the port an iron-cased fort was built near the breakwater, and Saint Nicholas, or Drake's Island, within the breakwater, has been furnished with strong fortifications, mounted with heavy guns. Various other forts and batteries also defend the place. The chief naval establishments are in Devonport and Stonehouse, the former having the royal dock-yard for building and repairing ships, the steam-yard for machinery and boilers, etc.; while Stonehouse has the victualing yard, naval hospital, marine barracks, etc. The Hamoaze is a favorite anchorage for men-of-war.

Plymouth, originally a fishing village, bore in very early times the name of Tamarworth, which, after the Conquest, was changed to that of Sutton, or South Town. It had become a considerable town under its present name in 1438, when a charter, confirming its old and granting many new privileges, was conferred upon it by Henry VI. From Elizabeth it obtained a new charter through the solicitation of Sir Frances Drake, and on the threatened invasion of the Armada the British fleet had its rendezvous here. Bonaparte arrived here in the *Bellerophon* in 1815. In the World War Plymouth was a submarine chaser base. Pop. (1936 est.) 208,182. Consult histories of the town by Worth (1871) and Williams (1898).

PLYMOUTH, Ind., city and Marshall County seat; alt. 790 feet; 84m. SE. of Chicago; on the New York, Chicago and St. Louis and the Pennsylvania railroad. The surrounding area is largely agricultural; industrial products are automobile parts and accessories, baskets, and road-working machinery. The city has standard schools and a public library, civic organizations and charitable institutions. Settled in 1835, it was incorporated in 1852. The water system is city-owned. Pop. (1930) 5,290; (1940) 5,713.

PLYMOUTH, Mass., town, county seat of Plymouth County, alt. 29 feet, on Plymouth Harbor; and on the New York, New Haven and Hartford Railroad; 38 miles southeast of Boston. The harbor, a part of Massachusetts Bay, is nearly landlocked, and contains about 2,000 acres of flats, on which are extensive «clam gardens,» the scientific cultivation of clams forming an important industry. Deep channels admit large ships and barges to the wharves. Foreign steamships bring large amounts of fibre directly to the cordage company from Yucatan.

The town has a variety of manufactures; they include cordage (the largest manufactory in the world of this kind); worsted goods; curtains; nails and tacks; insulated wire; and electrical supplies.

Plymouth is an electrical center, distributing to the surrounding towns light, power for street railways, and illuminating the Cape Cod Ship Canal each night.

It was here that the Pilgrims landed from the *Mayflower,* 21 Dec. 1620, and established the second permanent English colony in America. Plymouth Rock, on which they first landed, is carefully preserved in a State reservation, and is now covered by a granite canopy. Other places of interest in the town are: Pilgrim Hall (1824), a Greek temple, where books, pictures and other valuable relics of the Pilgrims and Colonial times are kept; Antiquarian House (built in 1809) overlooking the harbor and furnished with Plymouth antiques; and such old houses as the Sparrow (1640), Howland (1666), Bradford (1674), Harlow (1677) and Winslow (1730). Leyden street, on which the early settlers built; and Cole's Hill and Burial Hill, where many of the first settlers are buried. In the northern part of the town is the national monument to the Pilgrims, designed by Hammatt Billings and dedicated in August 1889. Its central figure is a granite statute of the Pilgrim Faith, with the four figures of Morality, Law, Education and Freedom at the base; the height of the monument is 81 feet. In Brewster Park, along the edge of Town Brook, is a bronze statute of the Pilgrim Maiden, designed by Henry Kitson and presented by the National Society of New England women.

Its beautiful situation and historic interest make Plymouth a popular summer and tourist resort. The Myles Standish State Forest, south of Plymouth, with 11,000 acres of woods and ponds, has log cabins for camping; and nearly half of the area is a wildlife sanctuary. The town has several parks and camp grounds, and there is good salt and fresh water bathing. Each Friday in August there is a commemorative pageant, the Pilgrims' Progress, imitating the old parade to church.

Plymouth was the seat of a separate colony until 1692 when town and colony were united with Massachusetts Bay. The Pilgrims called this settlement New Plymouth after Plymouth, England, their port of departure. Capt. John

Smith in 1614 had named it Plymouth also. It is governed by a board of selectmen. Pop. (1940) 13,100.

PLYMOUTH, N. H., town in Grafton County; alt. 514 feet; on the Pemigewasset River; 51m. N. of Concord; on the Boston and Maine Railroad. It is a summer resort for motor tourists, and a winter sport center, with ski trails. It has a public library, and is the seat of a state normal school. This school developed from an academy which was founded in 1808; in 1871 the academy property was turned over to the state, and the normal school was established; it has a model (practice) school. Just outside the town, overlooking the river, is the campus of the Holderness School for boys. Nathaniel Hawthorne (q.v.) died at Plymouth, May 18, 1864. The town was founded in 1763. Pop. (1940) 2,533. Consult Stearns, E. S., 'History of Plymouth, New Hampshire' (1906).

PLYMOUTH, N. C., town and Washington County seat; alt. 21 feet; on the Roanoke River; 141m. E. of Raleigh; on the Atlantic Coast Line and the Norfolk Southern railroads. It has canneries, and is a base for fisheries in Albemarle Sound, into which the Roanoke empties, a few miles below the city. In front of the courthouse is a marker commemorating the Battle of Plymouth: see PLYMOUTH (N. C.), ENGAGEMENTS AT. The town, founded in 1780, was named for Plymouth, Mass. Pop. (1940) 2,461.

PLYMOUTH, Pa., borough in Luzerne County; alt. 535 feet; on the Susquehanna River; 21m. SW of Scranton; on the Delaware and Hudson, and Delaware, Lackawanna and Western railroads. It is located in the anthracite region of Pennsylvania, and the mining and shipping of hard coal are the principal industrial occupations of its people. As in the case of many places in mining regions of the state, tunnels under the city have led to the weakening of foundations of some of the buildings. Plymouth was first settled in 1768, and later, when Pennsylvania and Connecticut were engaged in a dispute over boundary lines, it was claimed by both states. Pop. (1940) 15,507.

PLYMOUTH, Wis., city of Sheboygan County, alt. 847 feet, on the Chicago and North Western, and Chicago, Milwaukee, Saint Paul and Pacific railroads; 12 miles west of Sheboygan. The county fair grounds and the Wisconsin Cheese Exchange are here. Cheese, furniture, overalls, canned peas and beets are the main products. One mile north is Rocky Knoll Sanitarium, a State Hospital. It is governed by a mayor and council. Pop. (1940) 4,170.

PLYMOUTH (N. C.), Engagements at. When General Burnside had occupied Roanoke Island and Newbern in February and March 1862, the Union gunboats became active in patroling the waters of North Carolina and seizing the coast and river towns. Plymouth was occupied in June by Lieut. C. W. Flusser, United States Navy, and was held by him until relieved 15 June by a company of the 9th New York infantry; 10 Dec. 1862 the town was held by about 300 men under command of Captain Ewer, 3d Massachusetts infantry. Early that morning Ewer was attacked by Lieut.-Col. John C. Lamb, with the 17th North Carolina, a few cavalry and some artillery, in all about 600 men. Ewer's pickets were quickly driven in, and his men took refuge in the custom-house. Lamb's artillery opened fire; the town was fired in several places; and the gunboat *Southfield,* lying abreast of the place, received a shot in her boiler, which disabled her, and she drifted down the stream. The gunboat *Commodore Perry* coming up, Lamb retired after being in the town about an hour and reducing most of it to ashes. From 10 to 13 March 1863 the 17th North Carolina hovered about the place and made demonstrations upon it, but the regiment retired when the gunboats came up from Albemarle Sound. The gunboats had been relied upon to hold the place, but it was now strongly fortified on the land side and garrisoned, and early in April 1864 was held by Gen. H. W. Wessells, with four regiments of infantry, detachments of cavalry and artillery, in all about 3,000 men. As before, the principal reliance for the defense of the place was the navy.

In the spring of 1864 the Confederate authorities at Richmond determined that an attempt should be made to recapture Plymouth, and Gen. R. F. Hoke was put in command of a division for that purpose, and was to be assisted by Capt. J. W. Cooke of the navy, with the *Albemarle* then nearly completed. The *Albemarle* was an iron-clad vessel, similar to the *Merrimac,* carrying two heavy guns, and was built at Edwards Ferry, on the Roanoke, 30 miles below Weldon. She was built in a cornfield, and all the old iron in that section of the country was collected to make her armor. Hoke's division proceeded to the vicinity of Plymouth, drove in Wessell's pickets 17 April, surrounded the place on the land side from the river above to the river below, opened with artillery, made assaults on parts of the line on the 18th, which, with the aid of the gunboats, were repulsed, and prepared to storm the works as soon as the *Albemarle* could clear the river front of the Union vessels protecting the place with their guns. On the 18th the *Albemarle* left Hamilton, passed down the Roanoke and, favored by unusually high water, ran over obstructions placed in the river, ran past heavy shore-batteries, and at 3 A.M. on the 19th discovered the Union gunboats *Miami* and *Southfield* lashed together about half a mile below the town. Capt. C. W. Flusser was in command of the two vessels and had lashed them together with long spars, with chains festooned between them, it being his intention to get the *Albemarle* between the two vessels, which would have placed the Confederate vessel at a great disadvantage. Cooke avoided this by running the *Albemarle* close to the southern shore, and then, suddenly turning toward the middle of the river, dashed obliquely into the side of the *Southfield,* the long knife-like prow of the *Albemarle* penetrating 10 feet, making a large opening into the side of the *Southfield* and carrying her to the bottom within a few minutes, with a part of her crew. The *Albemarle's* prow had become entangled with the *Southfield.* The *Miami,* close alongside, opened with her heavy guns, and a shell fired by Flusser struck the *Albemarle,* rebounded and exploded, killing Flusser instantly. Lieutenant French took command, and attempted to board the *Albemarle,* but was repelled, and the *Miami* withdrew from the contest and ran down into Albemarle Sound. Next morning the *Albemarle* opened fire upon the forts and works near the river, and Hoke,

moving around to that side, attacked the works. After being several times repulsed, he carried them, Wessells surrendering his entire command. In killed, wounded and captured the Union loss was 2,834 men. The Confederate loss is not fully known, but Ransom's brigade alone suffered a loss of about 500 killed and wounded.

Soon after the capture of Plymouth General Hoke was ordered to the army in Virginia, but the place was held by the Confederates in some force, aided by the *Albemarle.* On 5 May 1864 the *Albemarle,* with two other vessels, ran down the river into Albemarle Sound and engaged a Union fleet of seven vessels, inflicting much damage, and returned to Plymouth. There was no Union ironclad that could cross Hatteras Bar and enter the North Carolina sounds, no other vessels could cope with the *Albemarle,* and it was reserved for Lieut. W. B. Cushing (q.v.) to execute a plan for her destruction. On the night of 27 Oct. 1864 he entered Roanoke River with two steam launches, each carrying a 12-pound howitzer and a torpedo. The launches carried 20 men, well armed with revolvers, cutlasses and hand-grenades. Passing near the pickets on the shore, Cushing approached the *Albemarle* at 3 A.M., and was hailed and fired upon with musketry from the shore and the vessel. Discovering that there was a circle of logs around the ship and about 10 feet from it, he turned back, and when about 100 yards away again turned, at full headway struck the logs and slid over them, and, in face of a crashing fire of canister and musketry, exploded a torpedo under the vessel and tore a large hole in her, "big enough to drive a wagon in," her commander says, and she soon settled to the bottom. Cushing with his men took to the water, he and one or two others escaping, while two were drowned and 11 captured.

On the 29th October Commodore Macomb, with his fleet, went up Roanoke River, and, arriving at the wreck of the *Southfield,* exchanged shots with the Confederate batteries, but finding that the channel of the river had been effectually obstructed, he returned, next day went by way of Middle River into the Roanoke, and on the morning of the 31st engaged the batteries on shore, which were supported by musketry from rifle-pits and houses. After an hour's contest, in which 10 vessels were engaged, a Confederate magazine was blown up; the works were abandoned, and the Union forces took possession of the town. Consult 'Official Records' (Vol. XXIII); 'Naval War Records' (Vols. IX and X); the Century Company's 'Battles and Leaders of the Civil War' (Vol. IV); Soley, 'The Blockade and the Cruisers.'

E. A. CARMAN.

PLYMOUTH BRETHREN, a religious sect which had its rise in the British Isles about 1827, when the Rev. John N. Darby, a minister of the Episcopalian Church of Ireland, associated himself with a group of dissenters in Dublin and formed a religious society of Brethren on a platform of Evangelical Calvinism. Similar local societies existed in various towns of Ireland and England, and Darby, while visiting the society at Plymouth, won over to his views a large number of persons, among them two or three clergymen of considerable distinction, one of them the Rev. Benjamin Wills Newton, another the Rev. James L. Harris, and the third the noted Biblical scholar, the Rev. Dr. Samuel Prideaux Tregelles. Plymouth now became the principal centre of the movement, and hence the popular title of the sect, Plymouth Brethren: the official title is "Brethren" or "Christians." A weekly newspaper was edited by Mr. Harris, and the sect made rapid progress, congregations being formed in every considerable town in England. In 1838 Mr. Darby went on an evangelizing mission to Switzerland and spent seven years in that country, chiefly in French Switzerland, where his success in gaining disciples and forming congregations was extraordinary among the Methodists and other dissenters: in Germany, too, in German Switzerland, in Italy and in France his opinions were received with no small favor: but French Switzerland, and in particular Geneva, Lausanne and Vevey, was his stronghold. When he returned to Plymouth in 1845 he sought to depose B. Wills Newton from the headship of the community there, charging him with a disposition to introduce priestly rule; but most of the Brethren upheld Mr. Newton, and Darby thereupon formed a separate assembly. At Bristol in 1848 there was a similar division, but this time into three sects, those siding with Darby, those siding with Newton and those siding with neither. Of these divisions there were subdivisions later. Four divisions of Plymouth Brethren had in the United States churches and membership at last report; Div. I — churches 134, communicants 2,933; Div. II — churches 128, communicants 4,752; Div. III — churches 81, communicants 1,724; Div. IV — churches 60, communicants 1,157. The Plymouth Brethren hold that an official ministry is an unchristian institution; among them all the male members are on an equal footing, and have the right to exhort in the meeting; after the opening exercises — a hymn or prayer — there is usually a pause to wait for volunteer addresses. See RELIGIOUS SECTS.

PLYMOUTH CHURCH, a church in Brooklyn, N. Y., of which Henry Ward Beecher was pastor for 40 years (1847–87). The church was organized in 1847; the present church building was erected in 1849. Dr. Beecher was succeeded by Lyman Abbott, who was succeeded in 1899 by Newell Dwight Hillis. The church membership is about 2,200.

PLYMOUTH COLONY, The. See MASSACHUSETTS, *History;* MAYFLOWER, THE.

PLYMOUTH COMPANY, The, in American history, a company formed in the 17th century, of Plymouth and Bristol merchants, and also called the North Virginia Company. It was incorporated in 1606, and obtained a charter from James I, with grant of land between Long Island and Passamaquoddy Bay. This company was the rival of the London Company. In May 1607, two ships were despatched to America bearing a company of colonists commanded by George Popham. An abortive attempt at permanent settlement was made on the Kennebec River, but Popham died and the remaining colonists returned home. The company still continued to exist till its reorganization in 1620 as the New England Company or Council for New England.

PLYMOUTH ROCK. See MAYFLOWER, THE; PLYMOUTH, MASS.

PLYMOUTH ROCK, a breed of fowls. See POULTRY.

PLYMOUTH SOUND. See PLYMOUTH, ENGLAND.

PLYMPTON, George Washington, American engineer and educator: b. Waltham, Mass., 18 Nov. 1827; d. 11 Sept. 1907. He was graduated from the Rensselaer Polytechnic Institute, Troy, N. Y., in 1847, and was professor of engineering and architecture at the University of Cleveland in 1852, professor of mathematics at the New York State Normal College, Albany, in 1853–56, and in 1857–63 occupied the chair of physics and engineering of the State Normal School, Trenton, N. J. He was professor of physics and engineering at Cooper Union, New York, from 1869 and director of the night school from 1879. He was also professor of physics and engineering at the Brooklyn Polytechnic Institute from 1863, professor of chemistry and toxicology at the Long Island College Hospital 1864–86, editor of Van Nostrand's *Engineering Magazine* in 1870–86, and published 'The Starfinder' (1878); 'How to Become an Engineer' (1892), etc.

PLYNLIMON. See PLINLIMMON.

PLYWOOD, a compound wood with surfaces of veneer, usually built up in odd multiple plies of 3, 5, 7, 9, etc., the various plies being glued together under pressure, the grain of the plies arranged to run in different directions. It is used in making musical instruments and their cases, household and office furniture, chair seats, packing cases, etc.

PNEUMATIC BUFFER, a mechanism consisting of a cylinder and piston, or of a series of cylinders and pistons, employed for various purposes, but more especially to absorb the recoil of large pieces of artillery, and to absorb the shock of falling elevators, printing presses, etc. The arrangement of pistons and cylinders varies according to the type and purpose of the engine to which the buffer is attached. The object in every case is to absorb sudden shocks and jars which otherwise would quickly wreck costly apparatus. The principle of the buffer is the transmission of the shock to the piston-rod, which thereupon forces the piston-head against the volume of air within the cylinder. The air is compressed and absorbs some of the shock, while graduated holes in the cylinder permit the air to escape slowly, and gradually the piston and load behind it are brought to rest. See AIR-CYLINDER.

PNEUMATIC CLOCKS. See CLOCKS.

PNEUMATIC DESPATCH. See PNEUMATIC TUBES.

PNEUMATIC TIRE. See BICYCLE; AUTOMOBILES; RUBBER TIRES.

PNEUMATIC TOOLS are a class of portable mechanical appliances operated by compressed air. The air pressure is conveyed through a flexible tube from a pressure tank to a miniature self-contained motor, and the tool is adjusted and applied by the hand. They are of two types — percussion and rotary. In the former the work is accomplished by rapidly repeated blows and in the latter by a boring action. They are used for a great variety of mechanical operations, such as drilling, ramming, hammering, riveting, caulking, boring, screwing, expanding boiler tubes and carving. A good representative of the percussion tools is the pneumatic hammer. It consists of a cylinder in which a piston works with a reciprocating (back and forth) action, actuated by compressed air admitted to and exhausted from the cylinder by suitably arranged openings.

A loose-fitting tool (such as a rivet-set, in case the appliance is employed as a riveter) is inserted in the front end of the cylinder, to which the compressed air is conveyed by flexible hose connections, and through the handle at the rear. To operate, the device is held by the handle and the tool is pressed firmly against the work. The operator then admits the air-pressure into the cylinder by pressing on the throttle lever, and starts the reciprocating hammer, which strikes the tool or rivet-set at each forward stroke. The action is similar to that of driving a chisel with a mallet or hammer, with the exception that the successive strokes are delivered with great rapidity, at a rate of speed as high as 20,000 blows per minute, and sound like a continuous buzz, the efficiency of the appliance being due to the frequency of the strokes rather than to the power of each individual stroke. Pneumatic percussion tools, in general, are made small enough to be operated by the hand, and they are adapted for various uses by simply replacing the tool piece at the front by other tools specially shaped to fit the particular kind of work. The arrangements for actuating and controlling the piston vary greatly in the different makes, but all of them belong to either the valve or the valveless form.

In the valve-hammers, a reciprocating valve acts in combination with the piston and regulates the admission and exhaust of the compressed air. They deliver a long stroke at a speed ranging from 1,500 to 3,500 blows a minute with great power, and are suitable for heavy riveting, chipping and caulking purposes. In the valveless hammers, the striking piston acts as a valve and controls the admission of the air-pressure to the alternate ends of the cylinder. They deliver a short stroke at a very high rate of speed, generally over 15,000 blows a minute, and are suitable for stone carving, beading flues, light caulking and other purposes requiring a light chipping action. Owing to their simpler construction, they last longer than the valve hammers and are more economical in air consumption relative to the number of blows delivered. For clipping purposes, the speed is greatly reduced, and the piston is constructed to act on a hinged link so as to impart a pincer-like action to the clipping jaws. As riveters, they range from the portable sizes to heavy stationary machines. Any ordinary pneumatic hammer may be employed in riveting, but such work is better accomplished, generally, by the regular U-shaped riveter designed for that purpose. (See METAL-WORKING MACHINERY). In riveters the compressed air is used at a pressure of 125 pounds to the square inch, while in the other forms the intensity is somewhat less, generally about 90 pounds to the square inch. Rotary pneumatic tools are commonly known as portable pneumatic drills. In wood-working, they are used for boring and drilling; in metal-working, they are employed in the operations of

tapping, reaming, screwing nuts on bolts, boring cylinders, expanding tubes, turning crank-pins, cleaning castings, grinding steam-pipe joints, etc. They are made in a large number of sizes, ranging from the light forms used for boring small holes up to the large machines requiring a two or three-horse-power motive energy. Originally they consisted of a small rotary engine with an attached feeding mechanism. Subsequently, to avoid the consequent waste of power, small reciprocating engines were designed, bringing them to the present form, in which they are used with marked economy for all purposes where heretofore the hand brace was employed. They are made in two forms — with single-acting or with double-acting oscillating cylinders, and work with an air-pressure ranging from 70 to 85 pounds to the square inch. In the former, the motor consists of two pairs of single-acting cylinders coupled to the opposite ends of a crank-shaft, the pinions of which gear with the spur-wheels on the tool-shaft. The whole mechanism is enclosed in a cylindrical metallic case. In the latter, two double-acting oscillating cylinders are geared to a crank-shaft carrying a single pinion which gears with a spur-wheel on the tool shaft. Another form — the Boyer piston drill — consists of a motor in the form of an oscillating engine composed of three single-acting cylinders carried in a rotary frame. The pistons being attached to a fixed shaft, the frame is caused to rotate by suitable gears and imparts its motion to the tool-shaft. The compressed air connections are flexible hose similar to those used in the percussion tools. Other forms of pneumatic tools of special application are the hoist, jack, stay-bolt cutter, mud-ring riveter, "bull-dozer" press, paint sprayers, sheep shearers and sand blasts. Their names define the purposes for which they are used. The hoist has largely replaced the ordinary hoisting chain; the jack is a modification of the hoist and is used by being placed under the piece to be lifted. Pneumatic tools are of modern origin and have been principally developed in the machine-shops of the United States, especially in connection with the repair departments of the railroads, but they are being rapidly introduced in European and other countries.

PNEUMATIC TUBES. Pneumatic tubes are employed to despatch letters, parcels, telegrams, etc., to a distance by the energy of compressed air. Their application was originally suggested by Denis Papin in 1667, when he read a paper before the Royal Society of London, describing a plan by which the air in a tube was exhausted in such a way that the piston working in the tube would be drawn in the direction of the suction, pulling with it an attached carrier. His idea was taken up and developed by several inventors, with more or less success, up to 1854, when the Electric and International Telegraph Company, of London, built in that city the first pneumatic despatch system which was actually operated for commercial purposes. It consisted of a lead tube 220 yards in length and one and one-half inches in diameter, in which the carriers were propelled in one direction only. Subsequently, the diameter of the tubes was increased to two and one-fourth inches, which were arranged to send the carriers in two directions — onward from, and inward to, the central station. At the latest report the English Postal Department operates about 601 miles of tubes, 40 miles of which are situated in the London district. In the English system the tubes radiate from the central station to the branch stations located at various points, the larger stations being equipped with two tubes — one for outward and one for inward traffic, while the smaller stations carry on the work through a single tube. The outgoing carriers are propelled by pressure and the incoming carriers are drawn in by the suction of a vacuum. The standard pressure used is about 10 pounds to the square inch, and a vacuum of about six pounds to the square inch, giving about the same speed in both directions. The tubes consist of lead pipes one and one-half inches to two and one-fourth inches in diameter, for interior use, such as the delivery of telegrams and parcels of small size, such as cash-carriers in stores, from one room to another in the same building; while the underground or street tubes are larger, ranging from two and one-fourth inches to three inches in diameter. The two and one-fourth-inch pipes weigh about eight pounds per linear foot and are made in lengths of 28 feet. When installed, they are enclosed in a cast-iron pipe three inches in diameter, made in sections of nine feet. The air-pumps are driven by steam-engines or by electric motors; those in the London district are worked by four 50 horse-power steam-engines. All of the carriers have gutta-percha bodies covered with felt, and are provided with buffers or pistons of felt attached to the front ends, which fit tightly in the tubes. The ends of the carriers are closed by elastic bands to prevent the messages from falling out, but they can be stretched sufficiently to allow the insertion of the message forms. The despatching and receiving apparatus originally consisted of a very complicated double-sluice valve, but it has been superseded by the D-box, a contrivance much simpler in form, which allows communication at will with either the pressure or vacuum mains, so that it is available for both sending and receiving. The carriers run at a speed of about 25 miles an hour.

In Germany, the Siemens system is employed. Its first extensive use was made in Berlin, in 1865, when 5,670 feet of wrought-iron tubing, two and one-half inches in diameter, were laid and connected the telegraph station with the Exchange. In this system, the tube forms a complete circuit, into one end of which the air is introduced under pressure while it is exhausted at the other end, thus maintaining a constant circulation, and also enabling the inserting and despatching of the carriers without temporarily shutting off the air current. The carriers were stopped at intermediate stations by placing a wire screen across the tube. The sending and receiving apparatus was constructed of two short pieces of tubing attached to a rocking frame so that either of them could be swung into the main circuit by the hand, whenever desired. One of them was open at both ends and was used in sending; the other was provided with a wire screen at one end, and when swung into the line of the main tube, allowed the air to pass through but stopped the carrier. At the present time, Berlin has in operation about 30 miles of tubes serving about 4

stations. As in the first experimental line, the tubes are laid in circuits, each of which serves a certain number of stations, but the air instead of being kept in constant circulation is stored up in large tanks, and turned into the tubes whenever it is required to despatch a carrier. Paris and Vienna have systems similar to that of Berlin. The carriers are run in trains, despatched at 15 minute intervals, with a maximum speed of 23 miles an hour. They stop at all of the stations on the circuit so that the carriers belonging to each station can be taken off, and those for the succeeding stations put in.

In the United States, the first attempt to establish a pneumatic despatch system was made by Beach, about 1872, who undertook the construction of a tunnel six feet in diameter, under Broadway, New York City. His system was called the "atmospheric railway" (q.v.) and contemplated the running of a car capable of seating 10 persons, through the tube, by the propelling energy of air pressure generated by a revolving fan. The project was abandoned after the completion of a small section of the tunnel. In 1904 the systems installed by the United States Post Office Department were as follows: The Philadelphia lines connecting the city post office with the Bourse, a distance of 2,974 feet, and its extensions to the terminal stations of the Pennsylvania, and the Philadelphia and Reading railroads, a total distance of about one and one-half miles; and the New York City lines, connecting New York City post office with that of Brooklyn, and with the Grand Central Station and the intermediate postal sub-stations, a total distance of about 10 miles. The installation is on the plan of the Batcheller system, very similar to that employed by the English. Compressed air at pressures ranging from 5 to 10 pounds per square inch is forced through wrought-iron tubes ranging from six to eight inches in diameter. They are laid in double lines so as to allow traffic in opposite directions, and are provided with automatic sending and receiving apparatus at all stations. In addition to the lines operated by the government, they are extensively used by private concerns in a great many cities, of which the systems operated by the Western Union Telegraph Company in New York City and Chicago are the most important. Since the perfection of automobile delivery trucks, city transportation has so improved that there is a tendency to discard pneumatic delivery for mail.

Bibliography.— More detailed information may be obtained from the following named publications: 'Pneumatic Tube Service' (published by the Postmaster-General, Washington); Batcheller, 'The Pneumatic Despatch System'; Kemp, 'Year Book' (London 1902); and various publications on the subject by the British Postal Service.

PNEUMATICS, a former name for the science that discusses the properties of gaseous fluids both at rest and flowing, also the properties of solids when the latter are immersed in gases. See CRITICAL POINT; GAS, NATURAL; GAS POISONING; GAS PRODUCER; HYDRODYNAMICS; LIQUEFIED AND COMPRESSED GASES.

PNEUMOGASTRIC NERVE, the vagus, or 10th cranial nerve (see CRANIAL NERVES), the lung-stomach nerve. It is formed by the junction of from 10 to 15 filaments which arise in the medulla oblongata. They form a flattened band which passes out through the skull with other nerves and pursues its course down the neck behind the carotids, being in the same sheath. Below the clavicle the right and left pneumogastrics go in different directions. The right pneumogastric enters the chest-cavity in front of the subclavian artery, gains the back part of the root of the right lung, breaks up into a coarse series of branches, being joined by the sympathetic, and forms the posterior pulmonary plexus. From this two cords of nerve-tissue continue downward on the right side of the œsophagus. An œsophageal plexus is formed about this tube, into which fibres from both sides enter. The fibres then converge to form a single trunk; this passes through the diaphragm and spreads out on the posterior surface of the stomach. The left pneumogastric passes into the thorax between the left common carotid and left subclavian arteries. It forms a plexus for the left lung corresponding with the right side. Its terminal branch passes in front of the œsophagus, and is finally distributed to the front portion of the stomach. The nerve contains both sensory and motor fibres and its function is complex. It is concerned in the functions of the lower part of the œsophagus. It is the important nerve of respiration; is the great cardiac regulator; and is the chief motor nerve of the stomach.

Diseases of the pneumogastric are comparatively rare, but by reason of its wide distribution, and because many of its fibres are distributed to a great number of structures, partial affections are not uncommon. The pharyngeal branches are occasionally involved in diphtheria and in nuclear disease. The pharynx becomes immovable and anæsthetic. Food may lodge in the gullet or enter the windpipe, causing coughing and strangling. Sometimes fluids regurgitate through the nose. In the larynx paralysis of the fibres may produce a confusing series of symptoms, with cough, diminution or loss of voice, hoarseness, impairment of respiration, pain, etc. The specialist is alone able to determine which branches are involved. Affections of the pulmonary branches affect the nutrition of the lung, pneumonia usually resulting from destruction of the vagus. Protracted hiccough is an affection of the vagus, as is also bronchial asthma. Unusual rapidity of the heart action (tachycardia) is due to temporary loss of control of the vagus on the heart. Cardiac palpitation is due to much the same agency; it is frequently associated with impaired stomach functions and is very frequent in hysterical and neurasthenic affections. An abnormally slow pulse (bradycardia) is usually due to an excess of stimulation of the vagus. Angina pectoris (q.v.) is a severe and usually fatal affection implicating the pneumogastric nerve. The involvement of the gastric branches may result either in loss of motion or sensation or excess of each. Sobbing and vomiting are largely induced by excessive irritability of the vagus. Gastralgia is also associated with disorder in this nerve. Loss of function may result in serious impairment of motion and secretion, although the sympathetic nervous system makes an important part of the nervous supply of the stomach. See HEART; STOMACH. And consult works referred to under these articles.

PNEUMONIA. See LUNG, DISEASES OF; PATHOLOGY.

PNOM-PENH, pnŏm-pĕn′, Indo-China, capital city of Cambodia, 140 miles northwest of Saigon, on the confluence of the Me-Kong and the Ton-le-Sap, lying partly in the plain and partly on a slight elevation, from which it gets its name, signifying in the vernacular "hill of abundance." It is the commercial centre of Cambodia, being situated near the Buon Phlau or Quatre Bras, the meeting place of Cambodia's four water ways. A palace of the king, and almost royal dwellings of the Buddhist priest, as well as the home of the French resident, are on the hill; the low ground near the river is occupied by native huts. The main commerce of the city is carried on by the Chinese. Pop. 73,729.

PNYX, nĭks, in ancient Greece, a hill in Athens where the people assembled to make decrees, pass laws, etc.

PO, pō (ancient PADUS, or ERIDANUS), the largest river of Italy, in respect both of its length and its volume of water. It rises on the confines of France and Piedmont in Mount Viso, one of the Cottian Alps, and flows rapidly eastward through Piedmont in the character of a mountain torrent, till, after having been augmented by several other mountain streams, it reaches Lombriasco. Here it begins to move more slowly and after passing Turin, becomes somewhat sluggish. It again flows eastward to the Adriatic Sea. It is about 400 miles long, and its drainage basin covers the larger part of northern Italy. In its lower course its banks are protected by levees and dikes, as the surface of the river is higher than the surrounding country. A number of rivers, chiefly from the Alps, flow into the Po. Its principal affluents are, on the left, the Clusone, Sangone, Dora-Riparia, Stura, Dora-Baltea, Sesia, Agogna, Terdoppio, Ticino or Tessin, Olona, Lambro, Adda, Oglio and Mincio; on the right, the Vraita, Tanaro, Scrivia, Trebbia, Nura, Taro, Parma, Enza, Secchia and Panaro. It drains the famous Lake Como, also Maggiore, Iseo and Garda. Pavia, Milan, Mantua, Parma and Modena are all located in its tributaries. After receiving the Adda its average breadth is about 650 yards. Below Piacenza, which it passes on the right, it is confined by artificial embankments, which are said to have originated with the ancient Etruscans, and notwithstanding the immense sums which have been expended upon them, and the engineering skill which has been exerted in order to render them perfectly secure, the most disastrous inundations have repeatedly taken place. The embankments themselves have added to the danger. The deposits made by the river are perpetually tending to raise the level of the water. This makes it necessary to make a corresponding increase in the height of the embankment, and the effect of these combined operations has been to lift the river so high above its natural bed that it is actually on a level with the tops of the houses in the city of Ferrara. The Po is well supplied with fish, including, among others, the shad, salmon and sturgeon. The deposits brought from the mountains are increasing the extent of the delta, which advances into the Adriatic at the rate of 200 feet each year.

PO RIVER, Engagement on. After two days' terrific fighting in the Wilderness (q.v.), with a loss of over 17,000 men, General Grant concluded to continue the movement by the left, and on the evening of 7 May 1864 put his army in motion for Spottsylvania Court House. The Second Corps, under General Hancock, the last to move, reached Todds' Tavern about 9 A.M. of the 8th and intrenched, being on the right of the army. A reconnaissance to Po River, two miles distant, developed Confederate cavalry on the opposite bank. On the 9th Hancock moved up to the right of Warren's Fifth Corps and took position and intrenched on high ground overlooking the Po and the Shady Grove road. The left of General Lee's line rested on a bend of the Po, and as reports indicated that he was moving in the direction of Fredericksburg, Hancock was ordered to examine the stream with a view to crossing it and making a reconnaissance along the Shady Grove road on Lee's left, crossing the river again by the Shady Grove or Block House bridge, or below it, in order to turn and attack Lee's left. The stream, some 50 yards wide, was crossed by Barlow's, Gibbon's and Birney's divisions late in the afternoon, Birney meeting a stubborn resistance from cavalry and a battery. After crossing, three pontoon bridges were laid and the troops were pushed toward the Block House bridge, Barlow in advance, but night coming on compelled a halt until morning, with Barlow's skirmishers close to the bridge. The orders for the 10th were that, while the rest of the army felt the Confederate position in front, Hancock was to ascertain the position and force of the enemy in his front and the location of his left flank and to hold his corps ready to advance. At daybreak Hancock made a close examination of the Block House bridge with the design of carrying it by assault, but the Confederates (Mahone's division) had been sent to that point during the night, and had intrenched, commanding the bridge and its approaches. Therefore Brooke's brigade of Barlow's division went down the river to find a crossing and General Birney sent two regiments out on the Andrews Tavern road to cover Brooke's movement. About half a mile below the bridge Brooke threw across a regiment which, after going a short distance, discovered a Confederate line of strong earthworks occupied by artillery and infantry. At this time, about 1 P.M., Hancock received a despatch from General Meade directing him to send two divisions to General Warren's position for an assault with Warren on the Confederate lines at 5 P.M. Gibbon and Birney were withdrawn to the other side of the Po, and as Hancock was to command the movements of Warren's Corps and his own, he accompanied them, leaving Barlow to hold the ground south of the river. When Birney began to withdraw, the regiments he had sent toward Andrews Tavern, having driven back Wade Hampton's cavalry, were attacked by infantry, and this evidence that Barlow was likely to be attacked caused General Meade to order Barlow to be withdrawn, as he did not wish to bring on an engagement south of the Po. Hancock was directed to give the matter personal supervision. It was about 2 P.M. when Barlow began to withdraw, at which time Brooke's and Brown's

brigades were south of the Shady Grove road, and Miles' and Smyth's brigades along the road, the left resting on a crest a few hundred yards from Block House bridge. In rear the ground was open back to the bridges and swept by the artillery of Lee's left. As the withdrawal began Barlow was attacked; Heth's Confederate division of three brigades and a battalion of artillery, which had crossed the river below the Block House bridge, attacked Brooke and Brown vigorously as they were withdrawing, and was driven back with severe loss when the two brigades passed to the rear and took position on a wooded crest on the right of Miles. Heth followed closely, Miles and Smyth were now retired to a crest in front of the bridges, and all the artillery, except Arnold's battery, was withdrawn and put in position on the north bank of the river. Heth again attacked Brooke and Brown, and was again repulsed with heavy loss. During the heat of this contest the woods on the right and rear of the two Union brigades took fire and the flames approached so close that upon the second repulse of Heth the brigades were ordered to abandon their position and fell back through the burning forest in good order. They immediately recrossed the river under heavy artillery fire. Many men were killed and wounded, numbers of the latter perishing in the flames. One gun of Arnold's battery, becoming entangled in the woods, was abandoned. Smyth's brigade was now crossed and deployed to protect the crossing of Miles; but before Miles could move the Confederates opened a furious fire of artillery from the front and left. Under cover of this their infantry attempted to cross the open ground in front of Miles, but Miles held the infantry in check, and the many Union batteries on the north side of the river silenced the Confederate guns, and Miles, taking advantage of the repulse, withdrew in order to the two pontoon bridges, one of which was immediately taken up, the other destroyed and the operation on the Po River was closed with severe loss on both sides. Consult 'Official Records' (Vol. XXXVI); Humphreys, 'The Virginia Campaign of 1864–65'; Walker, 'History of the Second Army Corps.'

POCAHONTAS, pō-ka-hŏn'tas, Indian princess: b. Virginia, about 1595; d. England, March 1617. She was the daughter of Powhatan (q.v.), a celebrated Indian sachem in Virginia and chief of the Chickahominy tribe. She discovered the warmest friendship for the English colonists, and undoubtedly did render many services to the struggling outpost. Investigations have, however, cast doubt on the traditional narrative of the rescue by her of Captain John Smith (q.v.). Smith, during his explorations, was taken prisoner by Powhatan, and after six weeks sent back to Jamestown. But he makes no allusion to the familiar story until 1616, when Pocahontas was in England; although in his 'True Relation' (1608) he had testified to her services to the colony. In 1616, in a letter to the queen, he says that "at the minute of my execution she hazarded the beating out of her own brains to save mine." But not until the appearance of his 'Generall Historie' (1624) does the tale appear in full elaboration. It has been thought that Smith's known tendency to embellishment and his desire to satisfy English curiosity led him to interpolate the story. Several writers have, nevertheless, contended for the general accuracy of Smith's account. It is argued, among other things, that it is very difficult to understand Smith's statements in the 'True Relation,' the employment of Pocahontas on difficult missions to the whites, and Pocahontas' own benefactions, such as the supplying of starving Jamestown with provisions, except on the supposition that Smith's narrative is substantially veracious. After Smith had left the colony in 1609 Pocahontas fell into the hands of an English expeditionary party (1613), who kept her as a valuable hostage. Her marriage to John Rolfe (q.v.) was solemnized in presence of the uncle of Pocahontas and her two brothers. This event relieved the colony from the enmity of Powhatan, and preserved peace between them. During her visit to England in 1616–17, Pocahontas attracted much attention, being apparently invested in English minds with quite a degree of royal dignity. She was often called the Lady Rebecca from the name received in Christian baptism. Her remains lie at Gravesend, and the burial is noted in the parish records. Consult Deane's edition of Smith's 'The Relation' (1866); Eggleston and Seelye, 'Pocahontas' (1879); Robertson and Brock, 'Pocahontas and her Descendants' (1887); Poindexter, C., 'Captain John Smith and his Critics' (1893); Fiske, 'Old Virginia and her Neighbors' (1897); Smith, E. B., 'Pocahontas and Capt. John Smith' (Boston 1914).

POCATELLO, pō-ka-tĕl'lō, Idaho, city and Bannock County seat; alt. 4,464 feet on the Portneuf River; on the Union Pacific Railroad; 234m. SE of Boise; has a municipal airport, with airline service. It has large railroad shops, stockyards, oil refineries, Portland cement plants, flour mills, and food processing establishments. Much livestock and poultry feed is prepared in Pocatello mills. The city is the seat of the University of Idaho, Southern Branch (Junior College), which has an historical museum. There is a local symphony orchestra. Pocatello was settled in 1881; incorporated, 1889. It has mayor and council. Pop. (1940) 18,133.

POCHARD, an English name for the male of a species of sea-duck (*Aythya ferina*), but often extended to both sexes and related species. It very closely resembles the American red-head duck, one of the book names of which is American pochard. The bill is broad and flat at the end with a terminal hooked nail and is less than the head in length. The hind toe bears a prominent flattened lobe. The inferior larynx of the male ducks is of strong bony construction. These ducks inhabit the Arctic regions, but migrate southward in winter to the coasts of Europe. Adults are 20 to 24 inches long and have a wing-spread one-half greater. They are marine in habits, and feed upon crustaceans, worms, mollusks and aquatic plants. The plumage is thick and dense, that of the male pochards being lustrous, darker and more brilliant than the plumage of the female. The pochard is represented in North America by the red-head, canvas-back and scaup ducks

(qq.v.) and in Asia and Africa by related species.

POCKET-MOUSE, a small burrowing nocturnal gray mouse of the genus *Heteromys,* which inhabits the arid regions of the southwestern United States and is related to the kangaroo rats and mice. They have cheek-pouches in which they carry into their burrows seeds, etc., for storage preparatory to winter famine.

POCOCK (or **POCOCKE), Edward,** English Arabic scholar: b. Oxford, 1604; d. 10 Sept. 1691. He was graduated at Corpus Christi College, Oxford, in 1622; entered the Church in 1629; became chaplain to the English Turkey Merchants in the same year; became lecturer in Arabic at Oxford in 1636 and Hebrew professor 1647; suffered some inconvenience because of his royalist sympathies under the Commonwealth; and lived in comfort after the Restoration. The first English Arabic scholar of note and a great Biblical commentator, Pocock is best known for his 'Specimen Historiæ Arabum' (1649) and an edition of Abulfaragius (1663).

POCOCK, Richard, English Oriental traveler: b. Southampton, 1704; d. 1765. He studied at Corpus Christi, Oxford; took holy orders and was advanced rapidly. He wrote 'Description of the East' (1743); 'Observations on Palestine' (1745); and 'Tours in Scotland' (1887, with biography by Kemp). He became bishop of Meath shortly before his death.

PODAGRA (Greek, "a trap for the feet"), that species of gout which recurs at regular intervals, attacking the joints, particularly the large joint of the great toe, and attended with sharp pain. See GOUT.

PODESTÀ, an Italian word, equivalent in its original meaning to a holder of power or authority. The office was first established in the 12th century by Frederick I in the principal towns of Italy, but became extinct in the 16th century. The podestà was entrusted almost with dictatorial power, the only limitation being a right of appeal from his decisions. Under Mussolini, the office was revived in 1926 for all communes except Rome. A podestà in Italy corresponds to a mayor in other countries.

PODIATRY (Gr. *ποῦς, ποδ,* foot, and *ἰατρεία* treatment). The art of caring for the feet both to cure and to prevent affections of them, called chiropody formerly (etymology usually given *χειρ,* hand, and *ποδ,* foot, as if treatment of hand and foot, but probably from *χειρυργ,* surgery, and *ποδ,* foot, euphony leading to the modification of the mid-syllable). The development of the art of caring for the feet has led to the recognition of the necessity not only for a special name but also for the definite evolution and regulation of the knowledge and practice of the art. The care of the feet has taken on a new significance in recent years. A number of serious constitutional diseases, as locomotor ataxia (perforating ulcer), diabetes (gangrene), Reynaud's disease and endarteritis obliterans (dry gangrene), as well as others, may give their first significant symptoms in the feet, so that it is all-important that the real meaning of them should not be missed at the beginning when most can be done for them. The chiropodist had developed from the "corn doctor," but there was manifestly need of more scientific training and more clinical knowledge, and as a consequence of this need the profession of podiatry was created. Like modern dentistry it represents an evolution from unprofessional work to a profession that now does much for the comfort of mankind. Both developments are due to American enterprise and the practical recognition and organization of valuable applications of knowledge.

The law of New York State (1919) regulating its practice defines: "Podiatry shall be held to be the diagnosis of foot ailments and the practice of minor surgery upon the foot limited to those structures of the foot superficial to the inner layer of the fascia of the foot; the palliative and mechanical treatment of deformities and functional disturbances of the feet; but it shall not confer the right to treat communicable or constitutional diseases of the bones, ligaments, muscles or tendons of the foot, or any other part of the body, or to perform any operation on the bones, ligaments, muscles, or tendons of the foot involving the use of any cutting instrument or the right to use any anesthetics other than local." This definition has developed after practical experience with the legislative regulation of chiropody. New York was a pioneer with New Jersey in the recognition of podiatry, but now 20 other States: California, Colorado, Michigan, Minnesota, Nebraska, North Carolina, New Hampshire, Maryland, Virginia, Massachusetts, Illinois, Louisiana, Rhode Island, Connecticut, Ohio, Vermont, Washington, West Virginia, Pennsylvania, Wisconsin and the District of Columbia have State regulation, and the benefit of it is so clear that probably all the other States will enact similar legislation in the next few years. There are colleges of chiropody or podiatry in California, Illinois, Ohio, New York, Pennsylvania and Massachusetts. In New York the educational requirements are three years of high school work, and after September 1921 four years or the equivalent. One year of full time school work or two years of evening classes are now required in the actual study of podiatry (anatomy, physiology, pathology of the foot and the treatment of its affections), and this is to be increased after 1921 to two full years of podiatric training. New York was a pioneer in the foundation of a pedic society, and this example led to the organization of similar bodies throughout the country, so that now 37 States have formal associations for the discussion of the problems of foot troubles and the proper regulation of the relations of podiatry to the community. There is a national association of chiropodists which co-operated with the United States military authorities during the war as to the care of the feet of soldiers. The new profession is represented by two organs, *Pedic Items* and *The Podiatrist,* in which many important articles appear. Many regular physicians, among whom Dr. M. J. Lewi of New York has been a leader, have been co-operating in the development of the new profession, and a number of contributions have been made to the special literature of the subject, including a 'Text Book of Practical Podiatry; Practical Podiatry (contains history of specialty, New York 1918); Surgery with

Special Reference to Podiatry (New York 1917).

JAMES J. WALSH, M.D.,
Author of 'Makers of Modern Medicine,' 'Old Time Makers of Medicine,' 'History of Medicine in New York,' etc.

PODICEPS, or **PODICIPIDIDÆ.** See GREBES.

PODEBRAD, pŏd'yĕ-brăd, **George Boczko,** Bohemian king: b. Podebrad, Bohemia, 6 April 1420; d. 22 March 1471. In youth he favored the Hussite movement, but remained with the moderate party during the reign of Sigismund; after the election of Albert V of Austria as Sigismund's successor he supported the Utraquists; invited Casimir of Poland to become king of Bohemia and compelled Albert to retire to Prague. Albert retained the title of king until his death in 1439 and Lipa was chosen regent of Bohemia. In 1444 after Lipa's death Podebrad became regent during the reign of Ladislaus, Albert's posthumous son, and though the young king came to reside at Prague in 1453 Podebrad continued to wield the authority of a monarch. Ladislaus died in 1457 and in 1458 Podebrad was unanimously elected king. He was crowned in 1459 and proceeded to institute various reforms in the government. In endeavoring to conciliate the Pope he banished the Taborites and other sects from the country, but was excommunicated in 1463, and a German crusade was inaugurated against Bohemia in 1466. Podebrad then recalled the banished Taborites, crushed the insurrection, defeated the German invaders and in order to secure the support of the Poles declared Ladislaus, heir of the Polish throne, his successor, his own sons to retain merely the family estates. He succeeded in firmly establishing his kingdom and died shortly after. Consult Jordan, 'Das Königtum Georgs von Podebrad' (1861); Richter, 'Georg von Podebrads Bestrebungen' (1863).

PODIUM, a foot-wall; *in architecture,* a low wall, generally with a plinth and cornice, placed in front of a building. A projecting low wall round the interior of a building, as a shelf or seat, and round the exterior for ornamental adjuncts, as statues, vases, etc.

PODMORE, Frank, English psychical student: b. 5 Feb. 1856; d. 1910. He was educated at Oxford, was one of the founders of the Fabian Society and was a member of the Society for Psychical Research. He published 'Apparitions and Thought Transference' (1894); 'Studies in Psychical Research' (1897); 'Modern Spiritualism: a History and Criticism' (1902); 'The Naturalization of the Supernatural' (1908); 'The Newer Spiritualism' (1910).

PODOCARPUS, a genus of trees and a few shrubs of the family. The species, of which about 60 have been described, are mostly tropical, distributed in the Australasian Archipelago, adjacent Asia, Japan, the South Pacific Islands, the Andes and in Africa. They are resinous, have fern-like leaves, small monœcious or diœcious flowers borne singly or in spikes either in the leaf-axils or subterminally. The pistillate blossoms are followed by small, berry-like fruits upon thick purple stalks, and subtended by fleshy bracts. The fleshy seed-stalks of some are used for food. In America a few are sometimes cultivated in greenhouses; others are sparingly planted in the South and in California. Well-drained loam suits them. Where indigenous, several species are highly prized timber trees. Of these the best known are probably the following: Totarra or totarra pine (*P. totarra*) which approximates a height of 100 feet and a diameter of 12, is largely used for ship-building in New Zealand where it is native; the gagali (*P. elata*) of Queensland, rises 100 feet, but has a diameter of only about three feet and is used for cabinet work; and *P. cupressina,* a Java species, which approximates 65 feet in height and whose easily polished yellow wood is used for house-building, furniture, etc.

PODOLIA, PODOLSK or KAMENETZ, formerly a government of West or "White" Russia, now included in the Ukraine. It lies north of Moldavia and of Bessarabia, Rumania. The surface is a table-land, strewn with hills. About three-fourths of the territory is arable or available for pasturage. The principal river is the Bug, although the Dniester forms part of the southern boundary. The capital is Vinnitsa (Pop. 11,000). It was the scene of serious upheavals during the World War. It has a fertile black soil, adapted to the growing of grain, tobacco and sugar beets. There is considerable manufacturing, chiefly flour, sugar and tobacco. Pop. about 3,500,000.

PODOLSK, a town in Russia, 26 miles south of Moscow. Pop. about 5,000.

PODOPHYLLUM, MANDRAKE, or **MAY-APPLE,** genus of hardy perennial herbs of the family *Berberidaceæ.* The four species are natives, two of China, one of the Himalayas and one of North America. The last species grows about 15 inches tall, bears one or two dark green leaves; in the axil of two-leaved specimens one or sometimes two fragrant saucer-like cream-colored flowers are borne. These are followed by a yellow, tender, insipid fruit which is somewhat edible. The dried roots and a resin obtained from them have been used in medicine, but are less popular than formerly. The fruits are sometimes called wild lemon and hog-apple. The name mandrake (q.v.) is more correctly applied to *Mandragora,* which is the mandrake of ancient history and romance.

PODURIDÆ. See BRISTLETAILS.

POE, Edgar Allan, American poet and prose writer: b. Boston, Mass., 19 Jan. 1809; d. Baltimore, Md., 7 Oct. 1849. His father was of a good Maryland family and his mother was a daughter of the once celebrated English actress Mrs. Arnold. Both parents were actors and were engaged at the Boston Federal Street Theatre at the time of their son's birth. Mrs. Poe, who outlived her husband, died in great poverty, leaving three children, who were adopted by friends. Edgar was taken into the home of his godfather, John Allan of Richmond and was treated in many respects as a child of the family. He was a handsome, precocious boy; the over-indulgence and unwise petting of his foster-parents aided in developing a naturally imperious and self-indulgent nature. When he was six years old the Allans took him

to England and placed him in a school at Stoke-Newington, then a suburb of London. He remained at the school for six years and there laid the foundation of his curious classical lore. The autobiographical story of William Wilson describes the old Manor House School and its quiet round of duties and pleasures. On his return to Richmond in 1821 he entered the English and Classical School of Joseph H. Clarke where he was prepared for college. He was quick and brilliant, excelling in languages and in athletics. But in spite of his talents Poe was unpopular; his extreme sensitiveness, his moody disposition, his pride of intellect kept his school fellows at a distance. He formed, during this time, a passionate devotion to the mother of one of his schoolmates and after her sudden death spent night after night of a bleak, dreary autumn, by her grave. At 17 he matriculated at the University of Virginia. He devoted himself to Latin, Greek, French, Spanish, Italian and took the highest honors in Latin and French. But his gambling debts were heavy and he was not allowed by Mr. Allan to return. After a short enforced stay in Mr. Allan's counting-house he determined to make his own career and ran away to Boston. There he published his first volume, 'Tamerlane and Other Poems' (1827), verses without any special originality and rough in execution. Poor and friendless he now enlisted in the army. He made an efficient soldier, was promoted to sergeant-major and was so attracted to army life that he again asked Mr. Allan's aid, and, through his influence, was allowed to enter West Point. He disliked the discipline of the school, however, and deliberately gave such grounds for offense that he was dismissed. Just before he entered West Point he had published a second volume of poems containing among others a revision of 'Tamerlane' and 'Al Aaraaf,' and after his dismissal he determined to make literature his profession. A second edition of his poems (1831), in such verses as 'Israfel' and 'To Helen,' gave promise of a real poet. In 1833 he competed for the prize offered by the *Saturday Visitor* for the best short story; and the award was made to 'A Manuscript Found in a Bottle,' one of the six stories which he had submitted. Mr. John Kennedy, the novelist, was one of the judges; he became the warm friend of the young writer and rescued him from deepest poverty by obtaining for him magazine hack work. Poe was at this time living with his aunt, Mrs. Clemm, and her daughter Virginia, in Baltimore, but soon moved to Richmond to write exclusively for the *Southern Literary Messenger*. He gained constantly in reputation and his weird tales and biting critiques rapidly raised the subscription list of the magazine from 700 to 5,000. In 1836 he married his young cousin, Virginia Clemm. Poe's life was restless and stormy; he left one position after another, just as he seemed on the point of a great success; his indulgence in opium and in intoxicants increased and he was often plunged into dire poverty, but his love for his beautiful wife was steadfast. Mrs. Clemm lived with her daughter and took care of the home. His wife was the inspiration of some of his purest poetry, of 'Eleonora,' of 'Annabel Lee,' of 'Lenore.' He uttered his forebodings over her desperate illness in 'The Raven,' and his grief for her death in the tender stanzas 'To One in Paradise,' and in the hopeless 'Ulalume.'

The letters he wrote to his mother-in-law are natural, simple and winning, and show Poe in a most attractive light. To her he wrote also the beautiful lines 'To My Mother.' In 1838 he moved with his family to New York where he held, for a short time, a position on the New York *Quarterly Review*, but the magazine was not so successful financially as had been hoped and Poe entered into an engagement with the *Gentleman's Magazine* and removed to Philadelphia. Mr. William Gowans, a well-known bookseller, who boarded with Mrs. Clemm in New York, gives emphatic testimony to Poe's courtesy and sobriety at this time. In 1839 his best stories were published in two volumes entitled 'Tales of the Arabesque and Grotesque' — among them 'Ligeia,' Poe's favorite tale, and the masterly 'Fall of the House of Usher.' A year later he began his work for *Graham's Magazine* in Philadelphia, and the fame of his poems, stories and critiques, together with Mr. Graham's excellent management, in two years raised the subscription list from 5,000 to 52,000. Much of his best writing was done for this magazine; in it were published among many other stories 'The Murders in the Rue Morgue,' which was immediately translated into French; 'The Descent into the Maelstrom'; and 'The Mystery of Marie Roget.' In 1842, either from native restlessness or because his fits of intoxication were increasing, he resigned the editorship of *Graham's* and two years later again moved to New York. In 1841 Mrs. Poe ruptured a blood-vessel and the next six years were filled with poverty, illness and agonizing alternations of hope and fear. At one time Poe achieved his desire of having a magazine of his own, as he had sole management of the *Broadway Journal*, but he had little executive ability and this enterprise failed. In January 1847 his wife died at Fordham, then a suburb of New York, and after this overwhelming sorrow, for two years and a half he struggled feebly against illness, weakness and opium. His most notable works during this period were 'Eureka,' 'The Bells' and 'Ulalume.' In October 1849 he fell ill in Richmond as he was starting for New York and was found delirious in the streets of Baltimore. He died in the City Hospital and was interred in the burial grounds of Westminster Church, near the grave of his grandfather, General David Poe.

Poe's character was complex and difficult; he was self-willed and self-indulgent, too often regardless of the rights of others, intensely proud and reserved, sometimes courteous and kindly, oftener moody and abstracted. He was keenly sensitive to sound and easily excited by stimulants. That he was not the degraded inebriate that Griswold depicted has been abundantly proved, but there is no doubt that his poverty and his frequent change of promising positions were caused in part by vacillating will and by recurring spells of intoxication. He was a dreamer and his imagination dwelt with the mystic and horrible; his mind was brilliant and acute and his sense of form and proportion exquisite.

The themes of Poe's poetry were few — man's loneliness, the hopelessness of struggle, remorse for a wrecked life. His poems bring no breath from the outer world. Theirs is a

land of dreams, of tempest, of fantastic terrors, of ashen skies, and through this land glide ghosts, birds of ill omen and crawling shapes. His poetry is not stimulating and has no moral quality; but has frequently an almost faultless literary form, vivid, if distorted imagination, and a haunting melody. His theory was that a poem should have complete unity in itself, and consequently should never be of great length, and that the poet must compose only when in a state of highly excited emotion. Poetry he defines as the «rhythmical creation of beauty.» His fame as a poet rests on a few short poems, 'The Raven,' 'Lenore,' 'Ulalume,' 'The Bells,' 'Annabel Lee,' 'The Haunted Palace,' 'The Conqueror, Worm'; and these in unity of design, in exquisite choice of melodic words, and in concentrated passion are well nigh faultless.

His stories are weird, filled with horrors and often glow with the putrescence of physical decay. They are carefully wrought and in such masterpieces as 'The Fall of the House of Usher,' and 'Ligeia' every word heightens the desired effect. The disintegrating power of fear on a sensitive and highly organized soul has never been more powerfully portrayed than in the former story. Poe's analysis of morbid and tortured souls is unsurpassed. His acute analytical powers are shown in such stories as 'The Murders in the Rue Morgue' and 'The Gold Bug'; his speculations usually hovered about the improbable and the horrible. His originality, his literary craftsmanship, are unquestioned, but he lacked the will and the moral conviction which would have brought his great gifts to their highest fruition. Editions of Poe are numerous. Griswold's (2d ed., 4 vols., New York 1856) contains a biased biography; the Stoddard edition (6 vols., New York 1895) errs in the same regard. Good editions are those of Gill (Diamond Edition, Boston 1874); of Ingram (2d ed., 4 vols., Edinburgh 1880; New York 1894); Harrison (Virginia Edition, notes by Stewart, 17 vols., Boston 1892); Stedman and Woodberry (10 vols., New York 1898). The 'Tales' were translated into French by Baudelaire; and also into German and Spanish. See FALL OF THE HOUSE OF USHER, THE; GOLD-BUG, THE; RAVEN, THE.

C., 'American Prose Masters' (New York 1909); Damon, S. F., 'Thomas Holley Chivers; Friend of Poe' (New York 1930); Ewers, H. H., 'Edgar Allan Poe'; Ingram, J. H., 'Edgar Allan Poe; His Life, Letters and Opinions' (London 1886); Krutch, J. W., 'Edgar Allan Poe; A Study in Genius' (New York 1926); Leigh, O., 'Edgar Allan Poe; the Man, the Master, and the Martyr' (Chicago 1906); Marks, J. A., 'Genius and Disaster; A Study in Drugs and Genius' (New York 1925); Phillips, M. E., 'Edgar Allan Poe, the Man' (2 vols., Chicago 1926); Robertson, J. W., 'Edgar A. Poe' (1921); Stedman, 'Poets of America' (New York 1880); Whitman, S. H., 'Edgar Allan Poe and His Critics' (New York 1860); Woodberry, G. E., 'Edgar Allan Poe' (in «American Men of Letters Series,» Boston 1885); and 'Life of Edgar Allan Poe, Personal and Literary' (2 vols., Boston 1909).

EMILIE WATTS MCVEA,
Late President, Sweet Briar (Va.) College.

POE, Orlando Metcalfe, American soldier: b. Navarre, Ohio, 7 March 1832; d. Detroit, Mich., 2 Oct. 1895. He was graduated from West Point in 1856, and in 1861 was chief of engineers in the Department of the Ohio. In that year he was commissioned colonel of the 2d Michigan Volunteers, served in the Virginia and Maryland campaign, was appointed brigadier-general of volunteers in 1862, and in 1863 was mustered out of the volunteer service and became chief of engineers in the 23d corps of the Army of the Ohio. He served in a similar position under Sherman in his invasion of Georgia, and was brevetted brigadier-general in the regular army in 1865. In 1865–70 he was engineer secretary of the United States lighthouse board, engaged in constructing the lighthouse on Spectacle Reef, Lake Huron, in 1873–84, and had charge of various river and harbor works in the Great Lakes. He was a member of the United States board of lighthouse commissioners, aide-de-camp to General Sherman, and at his death was chief engineer of the Northwest district.

PŒCILE, pē'sĭ-lē, a stoa or portico in ancient Athens, containing a picture gallery. The philosopher Zeno (q.v.) taught his doctrines here. See STOICISM.

POEM OF THE CID ('Poema de Mio Cid') is the most ancient monument of Spanish literature. The author, date and place of its composition are uncertain, but internal evidence points to some part of Castile, probably the neighborhood of Medina, as the place and 1140–60 as the date of its writing. The 'Poema' falls thus in time between the 'Chanson de Roland' and the 'Niebelungenlied.' In archaism of diction and prosody it stands nearer its French prototype; in unity of conception and the clean-cut outlines of the development of its story nearer to its German successors. The 3,730 lines of the epic fall into 152 stanzas of very varying length, the lines in each having the same assonant, though not rhyming ending. The metre is a rude Alexandrine, doubtless somewhat corrupted in the single manuscript, written apparently in 1307, which survives. The beginning is lost and a page, some 50 lines, from the body of the book. The theme of the 'Poema' is the wrongs, martial achievements in banishment and final triumphant vindication of Ruy Diaz de Bivar, known to Moors as Sid-i, that is, my Cid, i.e., my Lord, and to his contemporary Spaniards as El Campeador, i.e., the Warrior, German *Kämpfer,* though curiously enough later writers of either race favored the designation given by the other. The historical Ruy Diaz was a Castilian of distinguished birth. His wife, Ximena, was a daughter of Diego, Count of Oviedo. He was banished through court intrigue in 1080 or 1081 and for some years distinguished himself in partisan warfare with and against Moorish chieftains, fought notable battles at Almenara, Zalaca and Tebar, captured Valencia in 1094, formed an alliance with Pedro of Aragon in 1096 and, after five years of troubled rule at Valencia, died in 1099. His wife and followers evacuated that town in 1102. Out of this energetic and successful condottiere legend had in a half century erected a hero of a loyalty to his king as utter and more abject than that of Roland or of the German Hagen, a pattern of valor, of magnanimity and

of honor as that age conceived it, but yet a thoroughly flesh and blood man. The 'Poema' opens with the Cid going into banishment. Popular sympathy is repressed by dread of the king. He recruits his finances by cheating a Jew about security for a loan and his forces with "needy men" from all quarters. His wife, a Ximena, though not the true one, and his daughters, creatures of the poet's fancy, are confided to a monastery. He has a comforting vision of the angel Gabriel at Higeruela, captures Alcocer, defeats Moors who besiege him there in an inspiriting battle, but has still to "maintain himself by lance and sword." At Tebar he defeats the Count of Barcelona and shows to him a magnanimity which challenges his admiration and even belief. Here the Cid won the first of his famous swords, Colada, still shown as a treasure at the Armeria in Madrid. "Here," says the poet, "begins the *gesta* of My Cid" (line 1086) and with it the epic's second *cantar,* or canto. This tells of the greatest achievement of Ruy Diaz' life, the capture of Valencia and the setting up of his princedom there, interweaving with this the wholly fictitious tale of the marriage of the Cid's daughters, in compliance with the royal desire, to certain Infantes de Carrion. Here is introduced an "Eastern bishop," Jeronimo, who plays somewhat the part of Turpin in the Roland song. A combat with an uncaged lion seems conscious imitation of a passage in the French epic. Babieça, the steed who plays so large a part in the later ballads of the Cid, also appears. The third and last cantar opens with a fine battle piece and the winning of the Cid's second sword, Tison, still guarded as an heirloom in Spain, but deals chiefly with the bitter despite done to the Cid's daughters by the Infantes de Carrion at Corpes and with their subsequent humiliation and punishment in battle ordeal. It closes with the second and more brilliant nuptials of the daughters with the Infantes of Navarre and Aragon which have historic warrant, for since Alfonso VIII of Castile "kings of Spain are of his blood" (line 3,724) and Charles V in a royal charter of 1541 speaks of the Cid as "our ancestor." The most scholarly edition of 'Poema de Mio Cid' is by R. Menéndez Pidal (Madrid 1911). The most convenient, also by him, is in the 'Clasicos Castellanos' (Madrid 1913). An edition, in three volumes with text, translation and notes by Archer M. Huntington, was printed for the Hispanic Society of America in 1897. John Ormsby's 'The Poem of the Cid' (London 1879), has a spirited version of the finer passages, with a much condensed prose rendering of the rest, a good introduction and a table of the ancestors and descendants of the Cid. The relation of the 'Poema' to the facts is fully examined by R. Dozy in 'Recherches sur l'histoire politique et littéraire de l'Espagne pendant le moyen âge' (Leyden 1881). For later developments of the legend consult 'Chronica del Cid,' the basis of R. Southey's 'Chronicle of the Cid' (London 1808), and the more than 200 ballads collected by Duran in 'Romancero general' (2 vols., in 'Biblioteca de autores españoles') and by C. Michaelis in 'Romancero del Cid' (Leipzig 1871). BENJAMIN W. WELLS.

POERIO, pō-ā'rē-ō **Carlo,** BARON, Italian patriot: b. Naples, 10 Dec. 1803; d. Florence, 28 April 1867. Having espoused the cause of the Neapolitan liberals in 1828, he participated in the conspiracy of Avellino, and thereby incurred a long imprisonment. He was again imprisoned after the unsuccessful revolutionary attempt of 1847. Liberated in January 1848, in consequence of the revolution begun at Palermo, he organized the historic demonstrations of the 27th of that month, from which resulted the constitution of 10 February, under which he was nominated director of police and minister of public instruction. He soon resigned and was chosen to the Parliament as deputy for Naples. In July 1849 he was charged with conspiracy and, although not justly convicted, was sentenced to imprisonment for 24 years. In 1859 he, with many other political prisoners, was placed on an American ship for transportation, but was landed at Cork and returned, by London, to Turin. In 1860 he was elected to Parliament from Tuscany, and later became vice-president of that body.

POET LAUREATE, an officer in the lord-chamberlain's department of the royal household of Great Britain. The appellation was derived from *laurus,* a bay or laurel, in allusion to the ancient practice of crowning poets with a laurel wreath. Graduates in rhetoric and versification in the English universities were presented with a laurel wreath and were, in consequence, styled *Poetæ Laureati.* The royal laureate was merely one of these in the king's service. The first patent of poet laureate was granted to Ben Jonson in the reign of James I. The laureate was required to furnish an ode on the birthday of the sovereign or on the occasion of a national victory; but this custom was discontinued toward the close of the reign of George III. Since the time of Charles II the following poets have in succession held the office of laureate: John Dryden, Thomas Shadwell, Nahum Tate, Nicholas Rowe, Lawrence Eusden, Colley Cibber, William Whitehead, Thomas Warton, Henry James Pye, Robert Southey, William Wordsworth, Alfred Lord Tennyson, Alfred Austin, Robert Bridges, and John Masefield appointed in 1930.

POET AT THE BREAKFAST TABLE, The, a work by Oliver Wendell Holmes, first printed as a series of papers in the *Atlantic Monthly* in 1872. Like the earlier 'Autocrat' and the 'Professor at the Breakfast Table' it consists of rambling discursive talks on many subjects — religion, science, literature — with a frequent excursion into the realm of philosophy. The principal persons at the table are the Poet; the Old Master, a scholarly philosopher; the Scarabee, a withered entomologist; the poetic young astronomer; Scheherazade, a young girl who writes stories; and the Lady. All of these occasionally take part in the conversation, but more frequently the writer in his own person addresses the reader directly.

POETICS OF ARISTOTLE, The. The 'Poetics' of Aristotle, historically, and doubtless intrinsically, is the most important of extant works in literary criticism. Its relation to prior and contemporary treatises on poetry, including an Aristotelian dialogue 'On Poets,' is uncertain; yet this one surviving "Book" probably contains the net result of Greek reflection upon epic poetry and the drama. It

looks like the draft of a lecture, to be amplified in delivery, or else a record of the lecture, made by a student; or possibly a later Alexandrian abridgment of one or more Aristotelian writings on poets and the theory of poetry. With the discussion of tragedy and (partly by implication) epic poetry, we should expect the treatise to include more extended remarks on the effect of tragedy (the "catharsis," or purging of emotion in the audience) and on the nature of comedy. The Aristotelian "purgation of pity and fear" must be partly explained by a study of the actual emotions aroused and allayed in us by the best tragedies. Aristotle's conception of comedy must be inferred partly from scattered allusions in his other works, as the 'Rhetoric'; partly from a few specific references in the 'Poetics,' and from the general implications of that work; and partly from the 'Tractatus Coislinianus,' a garbled fragment on comedy, of Peripatetic, if not strictly Aristotelian, origin.

The history of the 'Poetics' proper down to the 8th century is very obscure. Aristotle's theory doubtless influenced his pupil, the eminent tragic poet Theodectes, and, through another pupil, Theophrastus, probably influenced Menander and the New Comedy. Through a Greek channel such as Neoptolemus of Parium, his doctrines, somewhat altered, found their way into the 'Ars Poetica' of Horace. During the Middle Ages the 'Poetics' was known to scholars in the East, being translated into Syriac in the 8th century. Upon an 11th century translation from the Syriac into Arabic was based the 'Commentary of Averrhoes,' which was rendered into Hebrew, and, by Hermannus Alemannus, into Latin, and through the Latin became known to Roger Bacon and, doubtless, other European scholars. Our earliest Greek manuscript (the best) dates from about the year 1000, but the 'Poetics' was not among the philosophical works which were translated from the Greek into Latin in the 13th century.

In the second half of the 15th century the Greek text was studied, in a number of manuscripts, in Italy. A translation appeared in 1498, and the *editio princeps* in 1508. Through Italian editors and commentators (as Castelvetro) a knowledge of the 'Poetics' was transmitted to other parts of Europe, and therewith sundry misconceptions as to the so-called Aristotelian "rules" for the drama. Thus in the 17th century, French tragic poets, as Corneille and Racine, were obsessed with a belief in the "three unities" of "time," "place" and "action"; the action of a drama, it was thought, should not only be unified, but should be represented as occurring within the space of "one revolution of the sun," and all in one place — whereas Aristotle, duly insisting upon unity of action, says nothing whatever about any "unity of place," and merely notes that the tragic poets of his day (70 years after the death of Euripides) aimed to confine the time represented in a play to "one revolution of the sun," and that the earlier Greek dramatists did not. Milton, in his conception of the tragic "catharsis," similarly follows the Italian commentators; the end of tragedy is to stir the mind to pity and fear, and by raising them, "to purge the mind of those and such-like passions"; when he adds, "that is, to temper and reduce them to just measure," he departs from Aristotle, whose conception was strictly medical — the tragic purge is complete, it leaves no residuum of "purified" fear and pity. The worst misconception, however, was peculiar neither to the Renaissance nor to the Middle Ages. To deem the 'Poetics' a set of "rules" imposed upon the free activity of the poet is a mistake that is made whenever the value of the treatise is dimly discerned, and its firm generalizations are not seen to be mingled with tentative suggestions and casual remarks which sometimes contradict one another. The correct attitude may be seen in Ben Jonson, who says (following Heinsius): "Those that can teach him [the poet] anything he must ever account his masters and reverence; among whom Horace and (he that taught him) Aristotle deserved to be the first in estimation. . . . But all this in vain without a natural wit and a poetical nature in chief; for no man so soon as he knows this, or reads it, shall be able to write the better; but as he is adapted to it by Nature he shall grow the perfecter writer."

For our own day, the best of modern editors says: "The book, taken as it is, with perhaps an occasional side-light from some of his [Aristotle's] other works, is intelligible enough; after a brief introduction, he gives us in outline all that he has to say on the subject immediately before him, the technique of the drama and the epic. He tells one, in fact, how to construct a good play and a good epic, just as in the 'Rhetoric' he tells one how to make a good speech. And in doing this he has succeeded in formulating once for all the great first principles of dramatic art, the canons of dramatic logic which even the most adventurous of modern dramatists can only at his peril forget or set at naught."

To Aristotle, Homer is the greatest of poets, but tragedy the highest form of poetry. In tragedy, the nearest approach to his ideal is Sophocles' 'Œdipus Rex,' though he pays much attention to Euripides' 'Iphigenia in Tauris.' With Homer and Sophocles he mentions Aristophanes; though his conception of comedy and tragedy was modified by the practice of his own age, his theory of the poetic art was in the main founded upon a study of these three. Of Æschylus, for some reason, he has little to say. Lyrical poetry he does not discuss, doubtless because to a Greek it fell under the art, not of poetry, but of music.

Aristotle conceives of poetry and the other arts as forms of "imitation." As a painter imitates a human figure in pigments, or as a sculptor imitates a man in bronze or in stone, so a tragic poet imitates an action — something done or suffered by human beings — in the medium of rhythmical language. This action is the very "soul" of the tragedy; the moral bias of the agents (shown in their habit of choice) is, like their ways of reasoning and explaining, subservient to the plot taken as a whole. The plot or action must be unified and complete — this is the only "unity" demanded by Aristotle. "Oneness" of hero — the only other "unity" mentioned by him — does not make a story an organic work of art. A good story is, in fact, like a living creature, no part of which could be transposed or removed, and to which nothing could be added, without distorting the whole. It follows that the poet

(the Greek word means *maker*) is a "maker" of plots rather than a versifier. What counts in the poet, then, is what we should call the constructive imagination. And in the finished work, what counts is the effect of the whole upon the competent judge — the arousal in him of the proper emotions (as by a reversal of fortune brought about through a flaw of character in some hero), and the right sort of pleasure in their relief (when we thrill with fear and melt with pity as the hero moves toward his doom and falls). To Aristotle our pleasure in art is allied to the pleasure we derive from the process of learning in general, and hence he dwells on the importance of "Discoveries" of identity in 'Œdipus Rex' and the 'Odyssey.' Consult Bywater's edition, 'Aristotle on the Art of Poetry' (Oxford 1909); Cooper's 'Amplified Version' (Boston 1913), and 'Poetics of Aristotle' (ib. 1923).

LANE COOPER,
Professor of the English Language and Literature, Cornell University.

POETRY. Poetry has been defined in many ways, and in the nature of the case the term means different things under different conditions. In general it may be defined as emotional and imaginative discourse in metrical form; that is, the representation of experiences or ideas with special reference to their emotional significance, in language characterized by imagery and rhythmical sound. On the side of concrete imagery the art of poetry is closely related to the arts of painting and sculpture; but it differs from these in that it is better adapted to the representation of continuity and movement, and also in that it can make use of purely abstract ideas as well as images. On the side of rhythmical sound it is closely related to music; but it differs from the latter in its capacity to represent both concrete and abstract ideas with some exactness. If the subject-matter is viewed by the poet objectively,— as existing outside and apart from his own personality,— the poetry may be narrative or descriptive; if subjectively,— that is, primarily as a personal experience,— the poetry is lyrical. Dramatic poetry combines these two points of view: it is objective for the poet, but presents the material subjectively through imagined personalities. Since poetry may deal with *general* as well as concrete subject-matter, there also occurs a type best called expository or didactic; but this, because of its small use of emotional values and imaginative expression, exists, as it were, close to the borders of prose. Further, on these types, see under LITERARY FORMS; LYRIC POETRY.

Poetry is the most primitive of the literary arts; that is, it normally develops before prose literature. Two theories of its origin have been proposed: that it arises from the elaboration and beautifying of prose discourse, and that it arises from emotional utterance in connection with song and dance. The latter view is the more widely held, and appears to be supported by evidence still observable among primitive peoples. That is, primitive man often expresses the emotional aspects of common experiences by means of a kind of communal art which includes music, dancing and simple verse, each element at first inseparable from the others. Indian festival dancer, and groups of singers at negro camp-meetings, still show this combination. As time goes on there is a tendency to differentiate the individual singer, composer or poet from the group, and eventually to differentiate the arts of music, verse and dancing. There is also a marked tendency, as civilization advances, to diminish the physical or sensuous aspects of emotional expression, and to increase the intellectual or reflective; so that poetry, originally existing only for vocal utterance, eventually becomes a thing to be read, and even to be read silently. But the rhythmic form remains as the evidence of its original connection with the other rhythmic arts. The persistence of this element is due, of course, not merely to historic, but also to psychological reasons: for rhythmic form furnishes a means of expressing emotion and at the same time of keeping it in control, and this is an essential condition of art. Moreover, by transforming the movement of ordinary speech, without depriving it of its normal meanings, rhythmic form seems to symbolize that idealization of reality which is another usual condition of artistic expression.

The precise nature of this rhythmic form naturally differs in the case of different peoples and languages, and according as the association between verse and music is more or less close. Thus the rhythms of Greek verse and Greek music appear to have been closely similar, whereas the rhythms of modern English verse and music differ very widely. For the modern Germanic languages, English included, rhythmic form results from the arrangement of speech in such a way that the principally stressed syllables tend to recur at equal intervals of time; the *number* of syllables within these intervals also tends to be constant, but with many exceptions. In the most common type of English verse two syllables normally occur for each measured stress,— that is for each measure or foot,— and the rhythm may be called *double*. Frequently, again, the norm is three, giving *triple* rhythm; less frequently four, giving *quadruple*. If the rhythm tends to open with an unstressed syllable it is called *rising;* if with a stressed syllable, *falling*. The common types of English metre, then, are the double rising, called Iambic; the double falling, called Trochaic; the triple rising, called Anapestic, and the triple falling, called Dactylic. A line of typical verse is made up of a fixed number of these measured stress-units or feet, and thus may be described as "iambic four-foot" (or "four-stress"), "trochaic five-foot" (or "five-stress"), etc. The stanza is a still larger unit of verse-form, being organized by the grouping of a given number of lines, of length either identical or varied according to a regular pattern, which are also usually linked by terminal rhyme,— that is, by the correspondence, in two words, of the accented vowels and all the following sounds. In the Germanic languages rhyme and stanza are the normal accompaniments of lyrical poetry, while "blank verse" (that is, unrhymed continuous verse, usually iambic five-foot) is the common form for epic and dramatic poetry; in French poetry rhyme is used more insistently, even in dramatic verse.

Greek Poetry.— In the classical age of Greek literature, the 5th century B.C., a high degree of literary development had already

taken place, yet at the same time the close connection of the three rhythmic arts remained conspicuous, as is evidenced by the fact that the lyrical odes of Pindar and the dramatic odes of Æschylus and Sophocles were written for musical performance in connection with processional or dance movements of the singers. The Greeks divided their poetry into three chief classes, epic, dramatic and lyric, the third class including subtypes called elegiac, iambic and melic (for an account of these see under LYRIC POETRY), all of which were characterized by different kinds of musical accompaniment. It happens that the body of surviving epic and tragic poetry of the Greeks is more complete and representative than that of their lyric poetry; but it is doubtless not for this reason alone that their epic and tragedy have largely influenced the great body of modern poetry, whereas their lyrics have exerted no such influence. For the Greek epic deals with story material which has remained impressively interesting, and the best Greek tragedies are concerned with emotional and spiritual problems of lastingly vital character; whereas the Greek lyrics are centred more in local and temporary matters, and also lack, for the most part, the subjective and spiritual qualities which are valued in modern lyric poetry. In the later age of Greek literature centring at Alexandria in the 3d century B.C., a new type of poetry was developed, the Pastoral, dealing with the environment and loves of real or imaginary shepherds,—a type widely imitated in succeeding ages.

Latin Poetry.—In the classical age of Roman literature, the 1st century B.C. and the 1st A.D., poetic composition was more largely confined to conscious imitation than in any other important period, and the poetic types of the Greeks became the types of Latin poetry. Certain differences of emphasis, however, naturally developed. Thus dramatic poetry occupied a much less important place than in Greece, while satiric, which by the Greeks was viewed as a minor form of the lyrical group, became highly important; indeed it is the Romans who gave us the type name Satire and who elevated the form, in the work of Horace, Persius and Juvenal, to one of prime significance as an expression of the spirit of their race and age. Another distinctive achievement was the elevation of expository or didactic poetry in Lucretius's great work, 'De Rerum Natura,' which remains the world's chief masterpiece of philosophic poetry.

Mediæval Poetry.—The poetry of the Middle Ages (that is, about 400 to 1400 A.D.) is divisible into two great classes, that arising from the mass of the people in the vernacular languages and that proceeding from the cultivated classes for whom Latin was the literary tongue. In the former class, narrative poetry takes an immensely preponderant place, developing on popular lines, especially those of the metrical romance, independent of literary tradition. It is to this vernacular poetry that we chiefly turn for the expression of that naïve or child-like spirit which is associated with the mediæval "age of faith" or "age of wonder,"—the purely popular poetry of earlier ages being largely lost. Mediæval Latin poetry, on the other hand, follows certain elements of the classical tradition, but is especially marked by the influence of the Church. Hence a number of new poetic types, most of them characterized by a large didactic element: in place of the national epic, religious epic and legend; in place of the lyric of love or wine, the hymn; and above all, appearing in many different types, the allegorical poem,—for the method of allegory is especially characteristic of the effort of mediæval Christianity to interpret all matters of this world in terms of the spiritual realm.

Renaissance Poetry.—The poetry of the Renaissance (that is, generally speaking, the period beginning in the late 14th century in Italy and the late 15th century in western Europe) is characterized by a turning away from the methods of mediæval literature, particularly allegory and didacticism, and a fresh interest in the types and methods of classical poetry, particularly Latin. Hence the effort to revive the formal epic and the formal satire; the imitation of the poetic tragedies of Seneca; a considerable development of pastoral poetry; and the revival of unrimed verse in various metres imitative of those of Greek and Latin. One notes also the saturation of poetry with the old pagan mythology, and a tendency to devote the art to the things of this world as distinguished from those of the spirit. A new type of lyric came into prominence, devoted to courtly love, for which the sonnet form was chiefly used; this fashion arose in Italy and spread to France, Spain and England.

Neo-Classical Poetry.—The principal European literatures were dominated, in the 17th and 18th centuries, by what may be called the neo-classical doctrines, which emphasized the theory and form, rather than the inspiring spirit, of ancient poetry. Poetry, in this school, was treated as a formal art, based on reason and on rules, with diminished emphasis on the elements of emotion and imagination; its spirit is well represented by Boileau's *Art Poétique* (1674) in France and Pope's *Essay on Criticism* (1711) in England. These poems also exemplify the revival of the didactic type, now frequently equivalent to the prose essay. Satire, formal epic and formal tragedy, are again characteristic of this age, as of the Renaissance; while in lyric poetry the more sentimental types, like the sonnet, tend to disappear and the more intellectual and elaborate, like the formal ode, to become prominent.

Poetry of the Romantic Movement.—The latter portion of the 18th century and the early portion of the 19th were characterized, throughout western Europe, by various tendencies commonly summed up in the vague term, "the revival of romanticism." The following are some of the marks of this era affecting the development of poetry: (1) A new emphasis on the lyrical, subjective and spiritual elements of poetry, with a disposition to view its imaginative processes as existing not merely for the sake of pleasure, but for the pursuit of truth by means of the higher intuitions of the mind. Important representatives of this aspect are Jean Paul Richter and his followers in Germany and Wordsworth and Coleridge in England. Wordsworth in his 'Prefaces' (1800–15) and Coleridge in his 'Biographia Literaria' (1816) discussed poetry as "the breath and finer spirit of all knowledge" and the imagination as a means of apprehending and revealing

truth. (2) A disposition to revive and value the natural or popular poetry of the mediæval period, as exemplified by Percy's 'Reliques of Ancient Poetry' (1765) and the lectures and researches of Herder in Germany. (3) A corresponding disposition to discard and contemn the formal rules of poetic art which had been taught since the Renaissance and to exalt in their stead individual freedom and novelty of form. Representative documents in this connection are Victor Hugo's preface to 'Cromwell' (1827) and a famous passage in Macaulay's essay on 'Byron' (1831), ridiculing the classicist's idea of "correctness" in poetry.

Poetry of the 19th Century.— The romantic attitude continued, for the most part, to dominate the modern period, with emphasis on individuality, freedom, variety and intensity, as the qualities most highly valued in poetry; though this was tempered by the return, on the part of individual poets (like Goethe in Germany and Matthew Arnold in England), for guidance and inspiration to the poetry of the ancients. Extraordinary metrical variety, in contrast with the regularity and conservatism of the neo-classical schools, is characteristic of the whole of the past century. Another characteristic is the preponderance of the lyrical type, so marked that a distinguished critic has said that "the history of modern verse is mainly the history of lyrical sentiment." That is to say, modern drama has been increasingly written in prose, modern epic has been developed but slightly, and narrative art has found its chief expression in the form of prose fiction. Perhaps the most characteristic poetic type of the 19th century is the dramatic monologue, which combines some of the elements of narrative with the subjective expressiveness of the lyric.

Recent Poetry.— The opening years of the 20th century have been marked by a revival of interest in poetry as a vital literary form and by a rich development of the spirit of experimentation. In particular, certain new movements or schools have arisen, analogous to similar phenomena in the arts of painting, sculpture and music; perhaps the most noteworthy calls itself by the name Imagism, a term brought into English from France. The qualities of this new poetry may be roughly described as consisting in (1) the attempt to represent freshly the fleeting impressions experienced by individual personality; (2) the rejection of all effort to interpret experiences generally or didactically; and (3) a preference for approximation and suggestiveness as distinguished from the attainment of finished form. The "new poetry" is especially marked by abundant metrical experimentation, often reaching the point of the abandonment of recognizable metre for rhythmic forms more eccentric or obscure than have yet been successfully analyzed. As in this respect there is a tendency to abolish the line between the art of verse and that of prose composition, so in the style or diction of recent poetry there is a disposition to avoid all distinction between the vocabulary and tone of the two kinds of discourse. This prosaic-poetic style was deliberately introduced into English poetry by Wordsworth at the end of the 18th century, was developed in different ways by such differently influential poets as Browning and Whitman and, in general, may be said to have gone far to do away with the older doctrine of a distinct vocabulary and style for poetry. On the other hand, it still remains doubtful whether the definite line between metrical and non-metrical composition can be blurred or neglected with lastingly pleasing results.

Bibliography.— For the general theory of poetry and the history of its forms, see Butcher's 'Aristotle's Theory of Poetry and Fine Art,' including a translation of the 'Poetics' of Aristotle (London 1898); Abercrombie, L., 'Theory of Poetry' (1926); Alden's 'English Verse' (1903); and 'Introduction to Poetry' (1909); Alexander's 'Poetry and the Individual' (1906); Andersen, J. RAYMOND M. ALDEN,
Professor of English, Leland Stanford Jr. University.

POETRY AND TRUTH. ('Aus meinen Leben: Dichtung und Wahrheit'). Goethe's 'Poetry and Truth' is one of the great autobiographies of the world's literature. It is divided into four parts, the first three of which were written and published between 1811–14, while the fourth was written mainly in 1830–31 and published in 1833. Each part contains five books; in style, composition and interpretation of life, the fourth part is inferior to the other three. The whole treats only of the first 26 years of its author's life, but Goethe held that "the most important period of an individual is that of his development." The material is distributed in such a way that Goethe's childhood is narrated from book one to the middle of book six; the account of his student-days begins with the latter half of the sixth book and continues through the 11th; books 12–15 are given to the consideration of his early manhood, when his first great successes as an author were realized. In spite of important experiences, part four does not open a new phase in Goethe's development, but it does bring the outer course of his life to its most decisive turning-point — his departure from Weimer. Goethe wrote 'Poetry and Truth' from the point of view of the scientist, the historian and the artist.

As a scientist he desired to picture his life as developing stage by stage «according to those laws which we observe in the metamorphosis of the plants.» As a historian he portrayed the general conditions of the times and revealed the relations between them and the individual. As an artist he did not feel tied down to facts for their own sake, but selects those that were of significance and moulded them so that they might become parts of a work of art. In the much-discussed title the word «Poetry» refers primarily to the artistic form of the work. One of the chief objects of Goethe's autobiography is to furnish a commentary for the understanding of his works. The leading topics of the different books are as follows: Book 1, Goethe's birth (1749), family and native city, Frankfort-on-the-Main; book 2, first inclinations toward poetry, fairy tale, 'The New Paris'; book 3, the French in Frankfort in consequence of the Seven Years' War, Count Thorane quartered with the Goethes; book 4, the boy's many-sided education, study of the Old Testament; book 5, youthful love, coronation of a German emperor in Frankfort. Book 6, Frankfort period concluded (1765), Goethe a student of law and literature at the University of Leipzig; book 7, German literature in the middle of the 18th century, fundamentals of Goethe's poetic talent; book 8, studies in art, return to Frankfort (1768), experiments in chemistry, religious convictions; book 9, Goethe a student of law and medicine in Strassburg (1770), German and French civilization, the cathedral, self-education and passion; book 10, mentor Herder, a trip through Alsace-Lorraine, love for Friedrike Brion of Sesenheim. Book 11, love-story continued, graduation as a student of law, alienation from French literature, admiration for Shakespeare, departure from Friedrike and from Alsace (1771); book 12, back in Frankfort, the Storm and Stress period, in Wetzlar, conditions leading to the conception of 'Goetz' and 'Werther'; book 13, trip from Wetzlar to Frankfort, comments on 'Werther' continued, publication and effect of both 'Goetz' and 'Werther'; book 14, Storm and Stress again, trip down the Rhine with Lavater and Basedow, influence of Spinoza, plan for a drama, 'Mahomet'; book 15, plans for an epic, 'The Wandering Jew' and a drama, 'Prometheus,' first meeting with the princes of Weimar, idea of settling permanently in Frankfort (winter 1774). Book 16, Spinoza again, poetry and profession, first meeting with Lili Schœnemann, Jung-Stilling; book 17, engagement with Lili, social and political conditions of the time; book 18, problems in prosody, journey to Switzerland as far as Saint Gothard; book 19, return to Frankfort, Lavater and his 'Physiognomy,' engagement with Lili broken, 'Egmont' begun; book 20, invitations from Weimar, the demonic influence in life, 'Egmont' continued, journey to Weimar (November 1775). Consult edition of Goethe's works in 'Deutsche National-Literatur' (Vols. XVII–XX, 1882–98); English translation by J. Oxenford, 'The Autobiography of Goethe,' «Truth and Poetry: From my own Life» (London 1846–48; new ed., rev., ib. 1881–84); Alt, C., 'Studien zur Entstehungsgeschichte von Goethes Dichtung und Wahrheit' (1898); Roethe, G., 'Dichtung und Wahrheit' (in *Berichte des Freien Deutschen Hochstiftes,* Jahrgang 1901, Frankfort am Main).

EWALD EISERHARDT.

POETS' CORNER, The, a popular name given a corner in Westminster Abbey in England, where there are memorials to many famous poets. Among those represented are Addison, Beaumont, S. Butler, Campbell, Cowley, Davenant, Drayton, Dryden, Gay, Goldsmith, Gray, Dr. Johnson, Ben Jonson, Longfellow, of America, Macaulay, Mason, Milton, Philips, Prior, Rowe, Shakespeare, Shadwell, Sheridan, Spenser and Thomson.

POEY, pō'āy, **Felipe,** Cuban naturalist: b. Havana, Cuba, 26 May 1802; d. there, 28 Jan. 1891. He was graduated in law from the University of Madrid, but abandoned his law practice and engaged in the study of natural history, later continuing his studies in Paris where in 1827 he aided in founding the Société Entomologique. He returned to Havana in 1833 where he made a study of Cuban fauna and in 1842 became professor of comparative anatomy and zoology at the University of Havana. In 1863 he was transferred to the chair of botany, mineralogy and geology. He published 'Memorias sobre la historia natural de la Isla de Cuba' (1860); 'Enumeratio Piscium Cubensium' (1875); 'Geografia de Cuba' (19 editions); etc. His most important work, 'Ictiologià Cubana,' was unpublished at the time of his death.

POGGIO BRACCIOLINI, pŏdj'ō brächō-lē'nē. See BRACCIOLINI, POGGIO.

POGROM. A riot, originally anti-Jewish, in Russia; marked by sudden attack, killing and looting; first occurred 1881, soon after assassination of Czar Alexander II. Organized by secret society aided by government officials hoping to divert discontent of people with political conditions into channels of race-hatred. In 1903 the Kishinev Massacre took place; about 50 Jews killed; hundreds wounded. After the October 1905 Manifesto a series of organized pogroms occurred in the Pale. Official connivance with pogroms in Russia has been established by investigations and publication of hitherto secret government documents. Jews were attacked in about 600 cities and villages, with thousands killed and wounded, property damage over 50 million rubles. The term «cold pogrom» is now applied to measures against Jews and other groups through boycott, social, civic, and other restrictions.

POGY. See MENHADEN.

POI, a native food or porridge made from flour obtained by grinding the roots of tara or taro, a plant grown in most of the Polynesian islands, especially in Hawaii. The tops are used by the natives as pot herbs. The root is ground on stones by the native women and made into mush, which, among the Hawaiians of the lower classes, is eaten with the fingers out of a common dish.

POILU, pwä-lü' Fr. adj. «hairy,» from poil, hair, beard: popularly applied as a noun during the war to the French soldier in the field, as descriptive of his occasional unshaven appearance. This nickname appears to be now as firmly established as «Tommy Atkins» (q.v.) in the British army.

POINCARÉ, pwăn'ka'rā', **(Jules) Henri**, French mathematician and physicist: b. Nancy, 29 April 1854; d. Paris, 17 July 1912. He studied at the École Polytechnique in 1873 and two years later completed his work at the École Supérieur des Mines. In 1879 he received the degree of Doctor of Sciences and took up his residence at Paris, where he soon became prominent at the University. In 1886 he received the appointment of professor of mathematical physics and calculus of probabilities; and 10 years later succeeded Tisserand in the chair of celestial mechanics. The Académie des Sciences elected him to its membership in 1887 and the Académie Française in 1908. Poincaré received many prizes for his work, among which may be mentioned the Prix Poncelet (1885); the prize awarded by the king of Sweden for the solution of the problem of the three bodies (1889); the Prix Reynaud (1896); the medal of the Royal Astronomical Society (1900); the Sylvester medal of the Royal Society (1901); the gold medal of the Lobachevsky Fund (1904); the Prix Bolyai (1905), and the gold medal of the Association Française pour l'Avancement des Sciences (1909). Poincaré's principal contributions to mathematical science were along the lines of theory of functions. His researches in physics were likewise marked by profoundly scientific research. The Fuchsian functions were introduced into mathematics by him. Among his most important works are 'Leçons sur la théorie mathematique de la lumière' (2 vols., 1889–92); 'Electricité et optique' (2 vols., 1890–91); 'Thermodynamique' (1892); 'Leçons sur la théorie d'élasticité' (1892); 'Les methodes novelles de la méchanique céleste' (3 vols., 1892–99); 'Théorie des tourbillons' (1893); 'Les oscillations électriques' (1894); 'Capillarité' (1895); 'Théorie analytique de la propogation de la chaleur' (1895); 'Calcul des probabilités' (1896); 'Cinématique et mécanismes potentiels et mécanique des fluides' (1899); 'Théorie du potentiel Newtonien' (1899). Some of these smaller works are embodied in his comprehensive 'Cours de physique' (13 vols., 1890). A number of other works have appeared from time to time in the scientific journals of France, Germany and the United States. Consult Slosson, E. E., 'Major Prophets of To-Day' (Boston 1914).

POINCARÉ, Lucien (Antoine), French physicist, mathematician: b. Bar-le-Duc, Meuse, 1862; d. Paris, 9 March 1920. He was educated at the Lycée of Bar-le-Duc, the École Normale Supérieure and the University of Paris. Dr. Poincaré taught in various lycées between 1886 and 1893 and from 1894 to 1900 was professor at the École Normale of Sèvres, also holding a chair in the Faculté des Sciences of Paris in 1899–1900. He was appointed inspector-general of public instruction in 1902. His published works include 'La physique moderne, son évolution' (1906; English, as 'The New Physics and its Evolution' 1907); 'L'Electricité' (1907; English, 'Electricity, Present and Future,' 1908), and contributions to scientific journals.

POINCARÉ, Raymond, war President of France: b. Bar-le-Duc, 20 Aug. 1860; d. Paris 15 Oct. 1934. He was educated at the lycées of Bar-le-Duc and Louis-le-Grand and studied law in Paris. He practised for a short time and was a contributor to political journals. In 1886 young Poincaré was elected deputy and soon made his mark as an earnest student of government and legislation. He allied himself with the moderate Republicans, whose leader at that time was M. Méline. He did not take a prominent part in the Dreyfus case and opposed some of the policies of Waldeck-Rousseau. At the age of 33 Poincaré entered the cabinet as Minister of Public Instruction, which he relinquished the year following to take the portfolio of Finance. In the many cabinet changes which followed he held various portfolios, but he acquired especial distinction as Minister of Finance in dealing with the involved and difficult affairs of the budget. M. Poincaré became a Senator in 1903, but he appeared to be indifferent to advancement in the public service and for nine years gave most of his attention to his legal practice, reaching the front rank of his profession. In 1912 M. Poincaré became Prime Minister, taking charge also of the Ministry of Foreign Affairs. He supported warmly the alliance with Russia and furthered the entente cordiale with England. As an advocate of proportional representation he supported a bill on this matter in 1912, which passed the Chamber but was thrown out by the reactionary Senate. On 17 Jan. 1913 Raymond Poincaré was elected to the Presidency of the Republic, the ninth to hold that office. The new President soon let it be known that he intended to be no mere figurehead, with cabinet ministers directing the policies and wielding all the power. His election was particularly pleasing to Russia and to England because of his support of the entente and his advocacy of the new spirit of nationalism. The new President was soon the most influential person in his government and was fully cognizant of the Teutonic menace which had administered more than one humiliation to France since the beginning of the century. To checkmate it, the three-year military service law was passed despite the violent opposition of the Radical elements; the amiable relations with England and Russia were fostered, the President making visits to the capitals of those countries, where he was enthusiastically received. All his efforts, however, were unable to avert the catastrophe, which like an avalanche burst upon France in 1914. The five ensuing years of Poincaré's life are the history of France; his able voice urged on his countrymen to great deeds and despite the efforts of the Defeatists he kept the courage, enthusiasm and patriotism of his people keyed up to the highest pitch. He visited the soldiers in training camps, trench and hospital and to him no less than to his Premier, Clemenceau, is due in great part the successful outcome. In January 1922 M. Poincaré succeeded M. Briand as Premier and served until 1924. In 1926 he returned to the office and took on the additional portfolio of Minister of Finance. He served as Prime Minister 1928–29, retiring from public life because of ill health, which caused him to decline the post of Premier again offered to him in December 1930. In June 1931 he was elected leader of the French bar. His published works include: 'Idées Contemporaines'; 'Études et Figures Politiques'; 'How France is Governed'

(1913); 'Au Service de la France'; 'Neuf Années de Souvenirs' (Vol. II); 'L'Europe sous les Armes' (Vol. III, 1913, 1926); 'L'Union Sacrée' (Vol. IV, 1914, 1927); 'L'Invasion' (Vol. V, 1928). Consult 'Raymond Poincaré: A Sketch' (New York 1915).

POINCIANA, a genus of leguminous trees, natives of tropical and subtropical regions, reaching a height of 20 to 30 feet. A variety known as «the peacock flower» is cultivated in frostless sections. The name is often erroneously applied to the Bird-of-Paradise plant, which is in fact a variety of *Cæsalpinia.*

POINDEXTER, George, American politician: b. Louisa County, Va., 1779; d. Jackson, Miss., 5 Sept. 1853. As a lawyer, he practised in Milton, Va., removing in 1802 to Mississippi Territory, where he became attorney-general in 1803. He was a member of the territorial legislature in 1806, and went to Congress in 1807 serving till 1813, when he was appointed United States judge for Mississippi, serving ably. He was Mississippi's first representative in Congress after her admission to statehood in 1817, and in 1819 ably supported General Jackson's conduct of the Seminole War. He was twice elected governor of Mississippi, and in 1830 was chosen United States Senator, in which office he ceased to support General Jackson and was even suspected by the latter of complicity in the plot to murder him. In 1835 he removed to Kentucky, but subsequently returned to Mississippi, where he resumed his old political association.

POINDEXTER, Miles, American legislator: b. Memphis, Tenn., 22 April 1868. He was educated at Fancy Hill Academy and Washington and Lee University, and removed to Walla Walla, Wash., in 1891. In 1892 he was elected district attorney there, and in 1897 removed to Spokane, where from 1898 to 1904 he was assistant prosecuting attorney. From 1904 to 1908 Mr. Poindexter was judge of the Superior Court. He became a member of Congress in 1908, uniting with the Progressive wing of the Republican party. He served as United States Senator two terms: 1911–17 and 1917–23. In the latter year he was made Ambassador to Peru, serving until 1928. He is the author of 'Ayar-Incas' (1930).

POINSETT, Joel Roberts, American diplomat: b. Charleston, S. C., 2 March 1779; d. Statesburg, S. C., 12 Dec. 1851. He completed his education at the University of Edinburgh and at Woolwich Military Academy, England, and in 1809 was United States commissioner to South America to investigate political conditions prevailing there. While in Chile he obtained the release of American merchantmen who had been seized by the Spanish authorities of Peru on a rumor of the declaration of war with the United States. He was elected to the South Carolina legislature on his return and in 1821–25 was a member of Congress; he served in 1825–29 as minister to Mexico and afterward allied himself with the «Union» party in strenuous opposition to the nullification issues. He was Secretary of War in 1837–41, and in 1840 was instrumental in the passage of the bill to reorganize the militia. The last years of his life were spent in retirement; he founded an academy of fine arts in Charleston, and published 'Notes on Mexico, Made in 1822; with an Historical Sketch of the Revolution' (1824).

POINSETTIA, a shrub (*Poinsettia pulcherrima*) of the family *Euphorbiaceæ.* It is a native of shady and damp tropical and subtropical Central America and Mexico, whence it was introduced into cultivation by Dr. Poinsett of Charleston, S. C., and distributed by Robert Buist of Philadelphia. The plant grows from three to six feet high in pots, its small yellow terminal flowers being surrounded with brilliant red bracts, varying to pink and white. It is a greenhouse plant in the north, available for Christmas decorations. The showy bracts are occasionally cut for large bouquets, etc., but usually the plants are left in pots. In mild climates, such as Bermuda, southern Florida and California, the plants are grown out of doors, but they never reach perfection, and must generally be grouped with other plants to conceal their bare, crooked stems.

POINT, that which has no part, but merely position. There are various definitions all to a degree unsatisfactory and defective because of the elemental nature of the term. Consult Heath, T. L., 'The Thirteen Books of Euclid's Elements' (Vol. I, New York 1908).

POINT BARROW, most northerly cape of the Alaskan peninsula; an important base for Arctic exploration. Here Wiley Post and Will Rogers (q.v.) died in an airplane crash in 1935.

POINT-DE-GALLE, point dė gäl, or **GALLE,** Ceylon, a fortified seaport town on a peninsula on the south coast, 21 miles west of Matura, and 66 miles south-southeast of Colombo. The appearance of Galle from the sea is singularly beautiful and picturesque. To the right is the fort, further on is the quay, surrounded by multitudes of canoes, while close to the harbor is the native town, white and shaded by numerous trees. Outside the town is a Buddhist temple. The trade of Galle consists chiefly in coir rope, cocoanut oil, arrack, chaya root, coffee, cotton, rice, ivory, cinnamon and tortoiseshell. It was under Dutch control from 1642 to 1796, when it was acquired by Great Britain. Pop. (1931) 38,424.

POINT GREY, British Columbia, Canada, a residential suburb of Vancouver (on the southwest), on English Bay and the north arm of Fraser River. It has a harbor of ten feet at low tide. There are 3 banks, 16 churches, electric light and power and electric railway, and five golf clubs. Pop. (1930) 13,654.

POINT-LACE. See LACE.

POINT PLEASANT, N. J., borough in Ocean County; alt. 20 feet; 9m. S. of Asbury Park; on Central of New Jersey and Pennsylvania railroads; a shore resort. Pop. (1940) 2,082.

POINT PLEASANT, Battle of, fought 10 Oct. 1774, at the mouth of the Great Kanawha River, by 1200 Virginians under Andrew Lewis (q.v.), against about 1,000 Indians led by the Shawnee chief Cornstalk (q.v.). After desperate fighting all day the white men won. Their loss was 75 killed and 150 wounded. The Indian loss, while not known, is believed to have been quite as great as that of the men under Lewis. By a treaty following the battle the Indians gave up to the whites an extensive tract south of the Ohio River. The battle proved to be of much importance in connection with the Revolu-

tionary developments in that part of the country, and its results had much to do with opening Kentucky to the whites. See COLONIAL WARS IN AMERICA, *Lord Dunsmore's War.*

POINTE-Á-PITRE, pwänt-ä-pētr, Guadeloupe, West Indies, the largest and richest town in the island of Grande Terre, the smaller of the two composing Gaudeloupe, with a good harbor at the mouth of the Rivière Salée, which separates Grande Terre and Basse Terre (see GUADELOUPE). Pop. 26,455.

POINTE-AUX-TREMBLES, Canada, town on the left bank of the Saint Lawrence River, northeast of Montreal, on the Canadian National Railway. Pop. 5,071.

POINTE-CLAIRE, Canada, town situated on the Island of Montreal, on the shore of Lake St. Louis, 10 miles west of Montreal, on the Canadian Pacific and the Canadian National railways. The town has some reputation as a summer resort. Pop. about 5,000; in summer about 7,000.

POINTER. See DOG.

POINTERS, The, *in astronomy,* two stars, Merak and Dubhe, in Ursa Major, so called because they point to the pole star.

POINTILLISM, the division of tones in painting by very small dots of equal size, causing the spherical shape to act equally upon the retina of the beholder's eye. The theory of complementary colors is systematically applied (see IMPRESSIONISM). Pointillism is an offshoot of impressionism, a movement that coincided with certain scientific research concerning optics: Helmholtz had published his works on the perception of colors and sounds by means of waves; Chevreul had established his beautiful theories on the analysis of the solar spectrum; and Charles Heary, an original thinker, had applied these new principles to æsthetics and had the idea of establishing relations between optics and the laws of painting. These researches found fruit in the work of the younger painters of the impressionist school, who thought of carrying its chromatic principles still further. These painters, working from about 1880 to 1889, endeavored to establish some laws concerning the reaction of tones — and particularly those concerning complementary colors — in such a manner as to be able to draw up a kind of table or system. Georges Seurat and Paul Signac were the promoters of this research; and to these two painters is due the method of Pointillism. The works of Seurat, Signac and other artists who have strictly followed the rules of Pointillism are somewhat lacking in life, spontaneity, caprice and charm; for the dryness and mathematical quality of the style (which reduces a picture to a kind of theorem excluding all that gives charm to a work of art) afford scant opportunity for the display of individual temperament. Besides Seurat and Signac other French painters of this so-called Neo-Impressionist School are Maurice Denis, Henri Edmund Cross, Angrand and Camille Pissaro (1831–1903). The Belgian, Théo Van Rysselberghe, is also an exponent of the Pointillist method. There are also a number of painters in the United States who work in this style. The Neo-Impressionists, like the Impressionists, are chiefly occupied with the problems of light, following the instruction laid down by Manet: "The principal person in a picture is the light."

POIRÉ, pwä-rā, **Emmanuel,** French caricaturist, known also by his signature CARAN D'ACHE: b. Moscow, Russia, 1858; d. 26 Feb. 1909. He first gained considerable reputation in France by drawings in various Parisian journals. He made particular study of military types, and especially came to depict French cavalry with great facility and truth. His work was collected into albums that called 'Psst!' (1898) containing drawings evoked by the Dreyfus case. His signature is an adaptation of the Russian word for "pencil."

POIRIER, Pascal, Canadian legislator: b. Shediac, New Brunswick, 1852; d. 1933. He received his education at Saint Joseph's College, Memramcook; was called to the Quebec bar in 1877 and to the bar of his native New Brunswick. Mr. Poirier became a dominion senator in 1885, sitting with the Conservatives. He was the leader of the so-called "Acadians," those who professed descent from the French colonists of Nova Scotia, who were expelled in 1755. He published 'L'Origine des Acadiens' (1887); 'Le Père Lefèbvre et l'Acadie' (1891); 'Des Acadiens deportés à Boston en 1775' (1909); 'History of the Maritime Provinces from the Acadian Point of View' (1914), narrow and bigoted and worthless as an historical record.

POISON ALDER, or **SUMAC.** See PLANTS, POISONOUS.

POISON GAS. In the First World War gas was first successfully used in 1915 by the Germans as a means of attack against the French and Canadian troops, who were holding positions on the Ypres salient. It came as a complete surprise to the Allies who retaliated and later employed poison gas as a weapon, using two methods of attack, commonly known as the gas cloud or mist attack and the gas shell attack. In the gas cloud attack the gases or asphyxiants used were chiefly chlorine and phosgene, which act through the lungs, causing death by suffocation. These gases are heavy, easily turned into liquids and are very poisonous. They are liquefied by cold and pressure and placed in metal cylinders, weighing over 100 pounds. The cylinders were taken up to the front line trenches and placed in special emplacements under the fire step. When the wind was favorable for an attack the gas was liberated by turning the stop-cock of the cylinders. The gas being heavy, was carried by the wind, close to the ground, towards the troops to be attacked, remaining in the bottom of the trenches, dugouts, etc., for some time if not removed. In the gas shell attack all areas within five miles of the front line were liable to be attacked. These shells were fired from heavy and light howitzers and trench mortars (Minenwerfer). The greater part of the explosive is removed and replaced by a poisonous liquid, which when the shell bursts, turns into a heavy vapor that hangs about the position for a long time. When fired alone, the shells can be detected by the *wobbly* motion made coming through the air, by the slight noise made on bursting and by the appearance of a whitish cloud when the shell bursts.

Gas shells contain a small bursting charge and a liquid chemical substance which is con-

verted into vapor and gas when the shell bursts. To insure satisfactory effects a large number must be discharged in a small space. The bursting charge, though less powerful than that of the ordinary shell, is nevertheless sufficient to produce a considerable explosive effect in addition to the actual gases. Protection of dugouts, cellars, buildings, etc., was given by well-fitting doors or by blankets sprayed with hypo-solution from a Vermorel sprayer. Practically no gas passed through a wet blanket, and the protection depended on getting a good joint at the sides and bottom of a doorway, so as to stop all draughts. This could be effected by permitting the blanket to rest on battens, arranged with a slight slope, against the door frame. The blanket should overlap the outer sides and a fold should lie on the ground at the bottom. The protection afforded by these means was as complete against lachrymatory gases as it was against cloud gas and poisonous shell gases. Chlorine is greenish yellow in color, is two and one-half times heavier than air, and hence rolls along the ground. Phosgene is colorless and is three and one-half times heavier than air. It acts as an asphyxiant, and is ten times as strong as chlorine. It has a delayed action on the heart, which acts two days afterward, and hence in trenches after an attack troops and horses were rested for 24 hours, inasmuch as any exertion after being gassed by phosgene makes the effects much worse. It requires from three to six hours to clean away chlorine and phosgene by natural ventilation.

Carbon monoxide has caused many casualties though it is not suitable for use as a war gas. In the immediate vicinity of a bursting explosive shell carbon monoxide is formed and may reach lethal concentrations, especially in confined spaces as within ships and fortifications. The gas has a much stronger affinity for the hemoglobin of the blood than oxygen and causes death by oxygen starvation of the hemoglobin. Because respirators offer no protection against carbon monoxide, Salvus sets were issued to machine gunners and batteries. These sets consisted of cylinders of oxygen opening into bags of waterproof material from which issue tubes leading to mouthpieces and cut off the men entirely from the outside air. Gas shells were ordinary shells from which the greater part of explosive had been taken and replaced by a poisonous liquid, which when the shell burst, turned into a poisonous gas or vapor, and being heavy, remained about the place where the shell burst. Only enough explosive was used to burst the shell and set the gas free. Mustard gas released from a shell contaminated a considerable area for some time because it was in the form of a heavy liquid which would vaporize or evaporate at a very slow rate. The skin would be affected by the formation of ulcers, sores, etc. This gas causes a loss of the sense of smell for other gases temporarily.

There are various methods of gas attacks—such as emanation, cloud or mist, and chemical shells. Emanation is the least important method and consists of scattering chemicals about trenches which are to be deserted. This chemical when brought in contact with moisture or stirred up by the digging of occupying troops produces a poisonous gas. The cloud or mist method consists of bringing gas up to the front line in cylinders or tanks under heavy pressure and releasing it when the wind is in a favorable direction for carrying it over enemy trenches. On a clear dry day the gas rolls along close to the ground as a faint green mist gradually growing thinner and less deadly as it advances and dissipates. On a damp day the gas, which has a strong affinity for moisture, appears as a greenish yellow cloud bank and is often harmless at as much as 200 yards. Chemical shells are dangerous because there is no warning. This method was used against the artillery which usually is too far back to be affected by cloud attacks except under very favorable circumstances. The average shell contained about five pounds of gas in liquid form which expanded when released by the explosive charge in about the same ratio as water to steam. A heavy and concentrated attack with these shells produces the same effect as a cloud attack, but with the added element of surprise. Methyl sulphate and pelite were among the most poisonous gases used in shells.

The bromacetone and xylylbromide (used mostly in German shells) are classed as lachrymal gases because they directly affect the lachrymal or tear glands of the eye causing a large secretion of tears and smarting of the eye which temporarily blinds the enemy. The effect of chlorine and bromine depend on the amount of gas in the atmosphere. Both kill by suffocation when in sufficient quantities. One part of chlorine to one thousand parts of air will cause paralysis of the glottis and men will tear their throats open with their fingers in their efforts to get air. Bromine effects are identical, but more violent. Phosgene gives a different effect, but the final result is the same. Men attacked by phosgene feel no serious effects for hours, when they suddenly sink into a fatal collapse with all the symptoms of heart failure. The anhydrides, when they come in contact with the moisture of the lungs, like phosgene, form acids corresponding to their bases, with similar effects. The effects of prussic acid gas are entirely different from the other gases. It acts directly on the nervous system, in dilute form produces dizziness, headache, pains in the chest and difficult breathing, coma and sometimes convulsions preceding the end. The respiratory irritant gases, or sternutators produce pain in the respiratory passages, nausea, vomiting, and at times, mental effects.

The accepted methods of defense against poisonous gases are the gas mask or helmet and the respirator. Those were of various kinds, but may be divided into two types—the P. H. helmet and the Box respirator. The P. H. helmet consisted of a double flannelette bag with two eyepieces and a mouthpiece through which the breath could be exhaled, but which collapsed if it were attempted to inhale through it. The flannelette was impregnated with solutions of phenol, caustic soda, hexamine and glycerine. The phenol constituted the neutralizing agent for the chlorine gas. The caustic soda was a protection against prussic acid and hexamine took out the phosgene. Signal stations, command posts, dressing stations and dugouts for troops in the support line when in the zone of gas attacks were generally provided with blanket curtains impregnated with these chemicals. The box respirator consisted of a small canvas haversack (called a satchel), of two compartments, one of which contained the metal filter with its

charge of chemicals; the other (the mask), called the facepiece, was made of rubberized material with mica eyepieces, a nose clip, a rubber mouthpiece shaped to be gripped in the teeth and terminating on the outside in a flat rubber valve similar to that on the P. H. helmet. The mask fitted the face closely and was held in place by broad elastic bands passing around the head.

The anti-gas horse respirator consisted of a flannelette bag with a canvas mouthpiece which goes into the horse's mouth and saves the flannelette from being bitten through. The bag was provided with an elastic band which passed round the opening so as to draw the respirator close to the face when in use. Inside the bag and attached to the canvas mouthpiece there was a canvas frame which was stitched on to the bag in such a way as to prevent the material being drawn into the nostrils when the respirator was in use. The whole was folded and carried in a canvas case provided with a flap. Horses can stand a higher concentration of gas than human beings without serious damage and hence it is not necessary to protect them against cloud gas attacks when they are a great distance behind the trenches. Nor is it necessary to protect their eyes. The respirator is primarily intended for use on transport animals when they are sent to the trenches with supplies, ammunition, etc. When not required for immediate use the respirator can be conveniently carried on the supporting strap of the breast harness, or if a zinc wither pad is worn, still more conveniently inside this pad. However carried, the case is steadied by being strapped on either side to the metal ring on the supporting strap, and its flap should be passed under this strap, between it and the numnah wither pad, and buttoned as in the *alert* position. Poisonous gases have been used in warfare with the intention of forcing men out of action, hampering artillery, preventing supports from advancing, and inspiring terror, so that an advance may be made with a slight opposition and some military advantage secured. Apart from a question of an advance, poisonous gases have been used merely as a means of causing casualties on the opposing side and of inspiring general terror.

Rest is the most important point of all in the general treatment of gas casualties. Men, and especially officers, should be warned beforehand that if lightly gassed they must refrain from moving about or calling out orders. Physical strain after gassing may involve the loss of a life that might otherwise have been restored in a brief time. The principle of attaining complete rest as soon as possible underlies the detailed advice for dealing with gas casualties, and is the reason for their detention at the casualty clearing stations. Arrangements should be planned beforehand at each casualty clearing station so that even a large number of gas casualties can be handled with discipline and control. Next in importance to rest comes the use of oxygen, protection from cold, special stimulants or drugs, venesection and methods for removing serous exudate from the lungs. Oxygen, if slightly administered, will generally lessen cyanosis, but the lung surface available for absorption is so small that the oxygen must be given in high concentration. Venesection gives real relief to men with deep cyanosis and a full pulse, but appears to be harmful in collapsed cases with poor pulses, and it should not be postponed until the patient passes into the dangerous state. Gas casualties, who show neurasthenic or cardio-vascular weakness after several weeks' treatment at the depot should be transferred to home hospitals.

For developments in chemical warfare in the Second World War see article under that heading.

POISON IVY, the *Rhus toxicodendron* of the natural order *Anacardiaceæ,* a climbing plant with pinnately compound leaves of three leaflets. Handsome at all times, it is particularly attractive in its rich autumnal color. The touch of its leaves and stems, even when dry, is disastrous to most persons, as it emits a glucoside that after a lapse of two to four days excites an eruption with violent itching accompanied by fever and followed by large and spreading vesicles. Laving of the skin with gasoline at once upon touching the plant, and if itching begins, the immediate sopping with very hot suds of laundry soap is effective. See PLANTS, POISONOUS.

POISON-NUT, a name for *Strychnos nux vomica.* See NUX VOMICA.

POISON OF SERPENTS. See SERPENT: RATTLESNAKE, etc.

POISON SPRINGS (Ark.), **Engagement at.** On 17 April 1864 a train of 198 wagons left Camden, Ark., and went westward 18 miles on the Washington road to collect forage and other supplies. It was guarded by 195 cavalry, 500 infantry and two guns, under command of Colonel James M. Williams, 1st Kansas Colored Volunteers. Next morning Williams was reinforced by cavalry, infantry and two guns, raising his force to 285 cavalry, 875 infantry and four guns. A greater part of the wagons had been loaded on the 17th, and on the morning of the 18th Williams started on his return to Camden, gathering forage on the way, and when about 12 miles from that place was intercepted by Marmaduke's cavalry. General Maxey soon joined Marmaduke, the united commands of about 3,200 men and four guns attacked Williams, and, in a four hours' fight, routed him, capturing about 100 prisoners, his four guns and the entire wagon-train. The Union loss was 92 killed, 97 wounded and 106 missing. Incomplete Confederate returns make their loss 17 killed, 88 wounded and 10 missing; their entire loss was about 155. Consult 'Official Records' (Vol. XXXIV).

POISONS AND POISONING. See TOXICOLOGY.

POISSON, pwä-sôn, **Siméon Denis,** French mathematician: b. Pithiviers, France, 21 June 1781; d. Paris 25 April 1840. He was educated in the Ecole Polytechnique, Paris, and occupied positions as examiner and professor in that institution for nearly 40 years. He was a member of the Bureau des Longitudes, professor of mechanics on the Faculty of Sciences at Paris, was appointed a member of the council of the university in 1820, and in 1837 made a peer by Louis Philippe. He wrote over 300 scientific papers and other works of great value, covering mathematics, physics, and astronomy, the most famous of his works being 'Traité de Mécanique' (1811). Among other works are: 'Théorie Mathématique de la Chaleur' (1835); 'Recherches sur la Probabilité des

Jugements en Matière Criminelle et en Matière Civile' (1837).

POISSON'S RATIO. See ELASTICITY.

POISSY, pwä-sē, France, a town in the department of Seine-et-Oise, on the left bank of the Seine, 11 miles southwest of Versailles. The weekly cattle market, chiefly for the supply of the capital, is said to be the largest in France. The town possesses considerable historical interest from the famous conferences of Poissy in 1561, in which the differences between Roman Catholicism and Protestantism were discussed at great length, but with no decisive result. Among the attendants were Charles X and Catherine de' Medici; the principal debaters were Theodore Beza and the papal legate Ippolito d'Este. It is also noted for its attractive church dating from the 12th century. Pop. prior to the World War, 6,000; (1926) 9,577.

POITIERS, pwä-tē-ā (formerly spelled POICTIERS), France, the former capital of the province of Poitou, at present of the department of Vienne, 61 miles southwest of Tours. It stands mainly on an eminence at the junction of the Clain with the Boivre, and retains its old walls and towers. The principal edifice is the cathedral, founded by Henry II of England about 1162 and built in a style exhibiting the transition from Romanesque to the Gothic. Other ecclesiastical buildings include the ancient church of Saint John, originally a baptistery; and the church of Saint Radegunda, the patroness of the town, with a crypt containing her tomb. The modern town-hall, the law-courts, occupying the palace of the former counts of Poitou, the museum, the library and university building also are notable. The university in 1936 had 1,949 students. There are some interesting Roman and early Gallic remains. Poitiers is celebrated in history for the battles fought in its vicinity between Poitiers and Tours, when Charles Martel defeated the Saracen army 18 Oct. 732, and when the French under their king John II were defeated by the English under Edward the Black Prince 19 Sept. 1356. It is one of the oldest towns in France and occupies the site of Lemonuen, the chief town of the Pictones, mentioned by Julius Cæsar ('Bell. Gall.' iii, 11; vii, 75; viii, 26). Its neighborhood has been the field of three of the greatest and most decisive battles ever fought in France prior to the world war, the first resulting in the defeat of the Visigoths under Alaric A.D. 507 by Clovis and his Franks. Pop. (1921) 37,663; (1926) 33,489.

POITOU, pwa-too, or **POICTOU,** France, a former western province now comprised in the departments of Vienne, Deux-Sèvres, and Vendée. This district was anciently inhabited by the Gallic Pictavi, from whose name that of Poitou is derived. Henry II of England acquired possession of Poitou by his marriage with Eleanor, heiress of the last Duke of Aquitaine. Philip Augustus conquered it in 1204. It was ceded to the English by the Peace of Bretigny (1360), but was recovered by Charles V. Its early history is identical with that of Aquitania. See FRANCE, *History*

POKANOKET, the name of a tribe of North American Indians. See WAMPANOAG.

POKER, or **DRAW-POKER,** a card game said to have originated in the United States, and of which there are several varieties, the most common being draw-poker. The game is played with a pack of 52 cards, and with usually not more than seven players. Play begins by the dealer placing a preliminary stake of unchanging value (called the "ante") in the centre of the table, after which, beginning at his left, he deals one card at a time, until each player has five cards. Each player, in turn, beginning with the first on dealer's left then decides whether he will "come in" or "drop out." If No. 1 elects to come in, he puts into the "pot" (the ante plus additions thereto) an amount equal to (usually double) the ante. Other players desiring to stay in do likewise in succession. Any player may increase ("raise") the first player's bet by the limit agreed upon before the game started, and any other player may raise the original raiser, continuing thus until all players desiring to stay in have put an equal amount into the pot. Those dropping out lay down their hands. Now comes the "draw." Each player remaining in decides which of his original five cards he desires to retain, and discards the others. The dealer then hands to each player remaining in, beginning at his left, a sufficient number of cards to fill the player's hand. A player, to improve his hand, may draw from none ("stand pat") to five cards. In descending order, hands are valued as follows: Royal flush (ace, king, queen, jack and 10 of the same suit); straight flush (any five cards of the same suit in sequence); four of a kind (as four tens); full house (three of a kind and a pair); flush (five cards of the same suit not in sequence); straight (five cards in sequence but of mixed suits); three of a kind; two pairs; one pair. After the draw, the betting is resumed. The first player to the dealer's left who remains in has the right to open the betting, or, if his hand does not warrant a bet, he may drop out. If he bets, then the next player to stay in, may equal ("see") the bet, increase it, or drop out; and so on until all players have put in an equal amount, or until all but one have dropped out, when the latter takes the pot. If two or more remain in the highest hand takes the pot. One player "calls" another by putting in an amount equal to the latter's bet. Where all "stickers" put in an equal amount it is a call around. Any player at any stage of the betting may call another's bet, and unless still another player raises, the hands are then displayed. Consult Foster, R. F., 'Practical Poker'; D'Allemagne, 'Les cartes à jouer'; and Jessel, 'Bibliography of Works in English on Playing Cards and Gambling.'

POKEWEED, POKEBERRY, POKE-ROOT, or **POCAN,** a strong-smelling perennial herb (*Phytolacca americana* of the family *Phytolaccaceæ*. It is a native of the United States from Maine to Florida and westward to Minnesota and Texas. It is 3 to 12 feet high, bears smooth, entire leaves, and long racemes of small flowers followed by dark purple berries which ripen in late summer and autumn. The young shoots and the seedlings are often eaten; the former like asparagus, the latter like spinach; the root, as it is quite poisonous, being first scrupulously removed. The deep crimson juice, formerly used to tint wine or preserves also has poisonous qualities. Its name was de-

rived from the Indian *pocan,* a dye-yielding plant. But the color is not fast, and is otherwise unfit for dyeing. Other popular names are garget, pigeonberry, inkberry and scoke. Its use as a rural medicine has been wholly abandoned because of many poisonings. In Europe the plant has become naturalized and there, as at home, is sometimes a troublesome weed. Two Asiatic species, *P. esculenta* and *P. Acinosa,* as well as the above species are occasionally cultivated for their young shoots and foliage.

POLA, a fortified maritime town in the peninsula of Istria, on the Adriatic, 55 miles south of Trieste; formerly the chief Austro-Hungarian naval station. The harbor's narrow entrance expands with its deep water into a basin large enough to accommodate the largest fleet. Forts and batteries on hills form the harbor's protecting background. Among the town's ancient ruins are the remains of an amphitheatre and two temples. Pola was most flourishing in the reign of Severus, when it harbored the Roman fleet. A triumphal arch, erected by Salvia Posthuma, is still in good condition and serves as a town gate. The principal modern edifice is a cathedral, built in the 9th century. Pop. (est. 1926) 57,843.

POLACCA, or **POLACRE,** a small sailing vessel, common in the Mediterranean. The masts, usually three, consist of only one spar, and so have neither tops nor cross-trees. They are usually rigged with square sails.

POLAND, the homeland of the Poles, in north-central Europe; formerly partitioned among Russia, Germany and Austria-Hungary; an independent republic from 1918–1939; partitioned anew by Germany and Russia in 1939. At the time of its extinction as an independent state in 1939 it included the region of Congress Poland, former Prussian Poland, Polish Galicia, part of Upper Silesia, and a part of the province of Vilna; area, 149,958 square miles; population 1 Jan. 1930, 30,737,448. For administrative purposes it was divided into the city of Warsaw, and 16 counties, subdivided into 276 districts. Only 25 per cent of the population is urban. The population of the principal cities on 1 Jan. 1930 was: Warsaw, 1,109,478; Lodz, 606,980; Poznan, 248,000; Lwow, 240,725; Cracow, 210,632; Wilno, 201,925; Katowice, 128,270; Lublin, 119,215; Bydgoszcz, 118,274.

Ethnologically Poland's population is composed of five chief elements: Poles proper (69.2 per cent); Ruthenians (14.3 per cent); White Russians (3.9 per cent); Jews (7.8 per cent), and Germans (3.9 per cent). The Poles are descendants of the ancient Lekhs, who dwelt along the Vistula in the 6th century. Ethnically they belong to the Western Slav group, but thorough mixing with other groups from prehistoric times has greatly modified the type, which is slightly below medium height, mostly blonde, with lengthened skull and fair skin. The Ruthenians form a branch of the "Little Russians," the purest Slavic type extant, much less affected by Mongolian admixture than the Russians proper. They are of medium height, rather slender, swarthy, with dark hair and brown eyes. The Lithuanians are a branch of the Letto-Lithuanian group, standing ethnically midway between the White Russians and the Baltic races. Physically they are well-built blondes, of medium height, with blue eyes, oval faces and fair skin. The White Russians are the descendants of two ancient Slav tribes (the Dregovitchi and Krivitchi), and for centuries have dwelt in Lithuania, where White Russian was long the official language. The Jews living in Poland belong to the Eastern division of the Hebrew race. A large proportion are descendants of Jewish fugitives from German religious persecution in the early Middle Ages. The German element in Poland is not all purely Teutonic, considerable Polish admixture having taken place.

Religion.—The predominant religion is Roman Catholicism, but no legal restrictions were imposed upon other faiths. The numerical rankings are as follows: Roman and Greek Catholics, 23,025,000 (74.9 per cent); Russian Orthodox, 3,802,000 (12.4 per cent); Jews, 2,978,000 (10.5 per cent); Protestants, 842,000 (2.0 per cent); and others (including non-believers) about 120,000.

Education.—Illiteracy was one of the big problems that confronted the new republic, whose adult population was over 60 per cent illiterate. During its independence 1918–39—and especially following the termination of the series of foreign wars that followed — Poland made heroic efforts, and no little progress, along educational lines. In 1930 it had 26,577 elementary schools (77,338 teachers and 3,715,041 pupils), 759 secondary schools (14,279 teachers and 203,387 pupils), 214 teachers' colleges, with 1,931 instructors and 35,515 students, and 731 professional schools, with 1,249 departments and 84,298 pupils. The last named group includes a dental school, a mining academy, an agricultural college, a veterinary college, an academy of art and two schools of commerce. In recent years elementary education has has been made free and compulsory; secondary education has been raised and standardized; while the rapidly growing universities have been liberalized and Westernized. The new republic has also raised the professional qualifications (and remunerations) of teachers, whose status and salaries are fixed by law, as are those of judges and other public servants.

Agriculture, Mining and Industry.—Poland is an agricultural country *par excellence,* and an immense agrarian problem is among the republic's heritages from its long tri-monarchial maladministration. The Land Reform Bill, passed in 1920; and the creation of a Land Department to engineer, and a state bank to finance the project of agrarian reform, indicate the seriousness of Poland's land problem and the energy with which it was attacked. While the Land Bill has undergone repeated modification since its enactment, its essential plan and purpose was to distribute, with state compensation to private owners, large estates (particularly those uncultivated or neglected) among landless Polish peasants for actual occupancy and use. By 1927 from 60 to 70 per cent of Poland's productive land was in the hands of small owners, none of whose shares exceeded 200 acres, and all arable land was under actual cultivation.

In mining, Poland ranked rather low in its pre-independence days, but its acquisition in 1921 of Polish Upper Silesia, with coal beds that are among the richest in the world (estimated at 63,901,500,000 metric tons), has transformed it from a net importer of coal (10,000,000 tons annually before the World War) to the second

largest coal exporting nation of Europe, after England, and the fourth largest European coal producer (over 37,500,000 tons in 1930) after England, Germany and France.

Industrially, too, Poland has made great progress since its independence. While state credits greatly stimulated Poland's industrial "boom" in the earlier years of its independence, ever-increasing home and foreign markets (the latter largely offsetting the loss of Soviet Russian trade) have made artificial stimulation of industries unnecessary. Under these circumstances, and aided by commercial treaties with nearly every important commercial country, Poland's further industrial development seems assured. Agricultural implements, machine tools, and oil refining are flourishing industries, with salt, potash, iron-ore, and zinc-ore among the other products of importance. The principal Polish industry, however, is still textile manufacturing, which employs about 130,000 operatives at 2,795,400 looms.

Constitution and Government.—The constitution of the Polish republic, as finally adopted in 1923, divides the powers of government into three branches (Executive, Legislative, and Judicial). There is a bicameral National Assembly or Parliament, composed of a Diet (Seym) and a Senate; a President, elected by the Assembly for seven years; a Council of Ministers; a Supreme Administrative Tribunal; and various other officers and departments. Executive power is vested in the President and the Council of Ministers, whose president, jointly with the President of the Republic and the particular minister concerned, must sign every law passed by the Assembly. The head of the republic is the supreme head of the army in time of peace. He has the power to call, adjourn or dissolve Parliament, with the concurrence of both houses, and, with the consent of the Diet, to declare war and make peace. All legislative power is vested in the Parliament, whose lower house, the Diet, is composed of paid members, elected for five years on the basis of proportional representation. Judicial control is vested in Administrative Courts, whose judges are appointed by the President of the republic, and whose highest department is the Supreme Administrative Tribunal.

History.—The early history of the Polish people seems shrouded in darkness. Certain slight indications point to a residence of the Polish tribes somewhere along the banks of the Danube. Mythical chiefs, however, in the new homes of the Poles on the Vistula were Lekh and Popiel, and after the death of the last Popiel, a prehistoric hero named Piast seized the crown, and with the fourth of his successors, Miecislav I (962–992) begins the accredited history of Poland. He succeeded in unifying the scattered or isolated tribes between the Vistula and Oder rivers into one state, and in 966 he was converted to Christianity and founded the first bishopric at Posen. His son Boleslav I conquered Pomerania and Danzig, and for a time also Bohemia. By founding the archbishopric of Gnesen he established the independence of the Polish Church from Germany. But during the reign of his son, Miecislav II, the young state fell to pieces by internal discord. Under Casimir I (d. 1058) the nobility rebelled, and a bitter and costly war was waged on Bretislav of Bohemia. However, the German emperor, Conrad II, adjusted matters peaceably. Boleslav II was driven out of the country, because of his intolerable cruelty, and his son and successor was poisoned. The latter was succeeded by Ladislas I (d. 1102), a brother-in-law of Emperor Henry IV of Germany, whose reign was prosperous. But after the death of Boleslav III (1139), his son, Poland was divided up among his four sons. In 1177 Miecislav III once more consolidated Poland, but he was deprived of the throne by an internal rising, and Casimir II reigned in his stead. His son, Leszek (1194–1227) and the succeeding Boleslav V were weak rulers, and whole provinces were estranged by greedy neighbors. Thus, Silesia and Pomerania were lost. There were also constant bloody risings and tribal wars among the pagan Borussians and Lithuanians in the northeast. Dire necessity compelled Conrad of Masovia, a Polish ruler, to beg the aid of the Order of the Teutonic Knights, his neighbors, and enforced by the latter the Poles, in the great and decisive battle on the Sirgune (1233) signally defeated the savage Borussians. There followed the awful period of Mongolian invasion. In the great fight at Wahlstatt, near Liegnitz, Silesia, the Tatars were victorious. A lengthy sort of interregnum followed, during which Silesia was taken from Poland and vast territories were wholly devastated by Mongolian hordes and other enemies. Finally, Venceslas III of Bohemia obtained the Polish crown But with the latter's demise, Ladislas II (1306–33), scion of the Polish royal race, initiated the long era of Poland's power and wealth, lasting till 1572. He nationalized Cracow completely and was solemnly crowned there, Cracow remaining from 1320 on the real capital of Poland. He also waged incessant and, on the whole, successful war against the Teutonic Order, thus strengthening the Polish national spirit. The son of Ladislas, Casimir the Great (1333–70) was forced to yield up some Polish soil to the Teutonic Order, but in 1366 he wrested Halicz and Vladimir from Russia, and also united Cuyavia with Poland proper. Louis of Hungary, as the nearest heir, reigned 1370–82, and the latter's daughter, Hedviga, was compelled to marry (1386) the Grandduke Yagello of Lithuania. Thus, the Yagello dynasty, the greatest in Polish history, attained to power, and automatically the union of Poland and Lithuania was effected. Poland thus became by far the most powerful state in eastern Europe. During this time it comprised the kingdom of Poland proper, made up of Cracovia and Silesia, Cuyavia and Masovia, and Lithuania. On 15 July 1410, the great battle of Tannenberg was fought, in which the Teutonic Knights were worsted with great slaughter, and in the Peace of Thorn, 18 Feb. 1411, the Order had to cede Samogitia to Poland. In 1413 the complete incorporation of Lithuania was decreed, and this led to the recognition of the equality of the nobility of both countries, and in 1433 "Red" Russia and Podolia were added to Poland. Yagello died in 1434 and was followed by his son Ladislas III who, in 1440, acquired by inheritance the crown of Hungary as well, but who lost his life in fighting the Turks at Varna, in November, 1444. An interregnum of three years ended

with the ascension of Casimir IV to the throne. An almost unintermittent war of 13 years' duration with the Teutonic Knights was successfully ended for Poland in 1466 by a second Peace of Thorn, the order being compelled to yield up West Prussia and Ermland, retaining East Prussia as a Polish fief. Casimir IV (d. 1492) was succeeded in rapid rotation by his three sons, John I Albert, (1492–1501), Alexander (1501–06) and Sigismond I (1506–48), the latter's reign being a glorious and enlightened one. Albert of Brandenburg, the Grandmaster of the Teutonic Knights, in 1525, was allowed sovereign rights over the territory of the Borussians, but only as a Polish vassal. Sigismond's son, Sigismond II Augusta, (1548–72) after great pains finally achieved the consolidation of Poland by an instrument termed the Union of Lublin, in 1569. During his reign Poland reached its greatest territorial expansion of about 380,000 square miles, with a population of some 15,000,000. All the gradually acquired lands, namely, Lithuania, Borussia (or Prussia), Volhynia, Podolia and Ukrainia, were welded with the older dominion into one political and economic entity. From 1572 until the partition, in 1795, Poland was an electoral commonwealth, and this method of choosing rulers, with its inevitable drawbacks, coupled with the lack of a middle class and the serfdom of the peasantry, gradually reduced the efficiency and the power of the whole state, finally ending in complete anarchy. With Sigismond II Augustus the male line of the Yagello dynasty became extinct, and thus the way was opened for internal and foreign intrigue. The first king under the new dispensation was Henry of Valois, brother of Charles IX of France, but Henry fled the country, after a three months' reign, to succeed his brother in France. Two years later, in 1575, the Polish parliament chose Stephen Bathory, the Hungarian. In 1586 the Swedish prince Sigismond was elected king, and he endeavored to unite Sweden with Poland. But Sweden soon tore loose from Poland. This led to a train of hostilities which were only permanently adjusted in the Peace of Oliva, 1660. Prior to this Poland lost Livonia, in 1657, and also the suzerainty over Prussia. John Sobiesky (1674–96), who rescued Vienna from the grip of an enormous Turkish army, was the last Polish ruler of ability, and after his demise the throne practically fell in every instance to the highest bidder, every one of the big Powers purchasing constantly a fraction of the Polish nobility to do yeoman service in Polish state affairs. When the Elector of Saxony, Augustus II, (surnamed The Strong) maintained his candidacy to the Polish throne against that of the Frenchman, Prince Conti, and when he became the ally of Peter the Great of Russia, Poland was hurled into the so-called Northern War. When Charles XII of Sweden was victorious for a time, in 1704, the Diet of Poland declared that Augustus had forfeited the crown and elected Stanislas Leszczynski in his stead. But in 1709 the latter had to renounce his rights, and after the death of Augustus II, in 1733, Stanislas attempted anew, with French aid, to recover the crown. However, Russia and Austria intervened, and Augustus III (son of the second) became king, 1733–63. Later at the instance of Catherine II of Russia, Count Stanislas Poniatovski was chosen king. When Russia, in 1765, championed the cause of the Dissidents, the Confederation of Bar was organized by a faction of nobles in Poland, and this led to internal war and great disorder. This had to serve as pretext for the joint intervention of Russia, Austria and Prussia, culminating in the first partition of Poland, 5 Aug. 1772. By this act of violence, sanctioned though it was in a measure a month later by the impotent members of the Polish Diet, Poland lost all told a full one-third of its remaining territory, the major portion going to Russia, Prussia obtaining the province of West Prussia, and Austria most of Galicia. After this first partition a party of patriots was organized in Poland having the redemption of their country in view. But Russia, by a cunning system of bribery used among the nobility, neutralized these efforts, securing a body of partisans strong enough to issue, at Targovicza, a decree declaring the new reform measures passed by the Diet, and more particularly the more liberal Constitution, an infringement of their rights and privileges, on 3 May 1791, and thus being null and void. This was the signal for new civil strife, and that fact again induced the ruler of Prussia, against previous promises, to side with Russia and to consent to a second partition of Poland, 4 Jan. 1793. By its terms Russia obtained the full half of the remaining territory of Poland, with 3,000,000 inhabitants, while Prussia claimed for herself Posen and other parts, with more than a million of population. Polish patriots rose under Kosciusko, but Russian and Prussian armies entered Poland from the north and south, and the Polish forces, after bravely resisting and with initial successes, were overwhelmed. Kosciusko, dictator at Warsaw, was rendered impotent by dissensions among his adherents, and on 10 Oct. 1794 he sustained a decisive defeat at Maciejovicz, and was taken prisoner. Soon after the Russian general, Suvaroff, entered Warsaw and all resistance ceased. The third and last partition was then in order, and by its terms of 24 Oct. 1795, Russia, Austria and Prussia divided the last of the spoils amongst them and Poland as an independent political configuration ceased to exist. Its last sovereign, Stanislas, died a few years later (1798) as a pensioner of Russia.

Napoleon made clever use of Polish aspirations, but the hopes built on him came to nought. True, after a Polish legion of volunteers under Dombrovski had fought valiantly under his colors, he did create a grand duchy of Warsaw. This was done after the Peace of Tilsit, 1807, when he made the king of Saxony, Frederick Augustus I, its sovereign. But this fragment of ancient Poland, although by the Peace of Vienna in 1809 it was added to from Galicia, was merely meant to be a satellite of Napoleon's own ambitious schemes and after 1812 the whole so-called grand duchy of Warsaw went to pieces. By the Vienna Congress Russia again obtained by far the lion's share of Poland. This Russian share now was called the kingdom of Poland and received certain assurances, under international guarantee, and in especial a constitution and administration of its own. In 1818 the first Polish Parliament was opened, but in 1825 already freedom of

Partition of Poland 1807, 1815, 1848

the press and other privileges were curtailed or abolished. After the death of Alexander I of Russia Poland was again governed like a subject province. The consequence was the rising of November 1830 under the inspiration of Mickievicz and Lelewel. The whole of Poland rose. Under General Chlopicki a provisional government was formed, with Prince Adam Czartoryski at its head. The Polish Parliament pronounced the house of Romanoff as unworthy to rule Poland, 21 Jan. 1831. A Russian army of 120,000 under Diébitsch marched upon Warsaw. At Grokhov a battle unfavorable to the Polish cause was fought and the Polish forces had to retire toward Warsaw. Prince Radzivill, who had succeeded Chlopicki, resigned in his turn, but General Skrzynecki failed to beat the Russians at Ostrolenka and the cholera destroyed, besides, more Poles than the war. On 6 and 7 September the Russians took Warsaw by storm and that was the beginning of the end. An amnesty 1 Nov. 1831 contained many exceptions. The constitution was altogether abrogated and a systematic process of Russification was inaugurated. A new revolution was planned and in February 1846 it broke out, but was put down at once. Cracow now lost its autonomous position and was incorporated with Austria. In 1848 as part of the great liberalizing movement in Europe, another rising took place, but was drowned in blood. The movement for a restoration of Poland continued, however, in secret. On 15 Oct. 1861 there were new disturbances in Warsaw. Thousands were incarcerated by the Russians or deported to Siberia and the estates of many nobles were confiscated. On 8 Jan. 1862 a brother of the Tsar, Grand Duke Constantine, became governor of Poland, with a great plan of reforms, and a Pole, Marquis Wielopolski, as coadjutor. But on 3 July an attempt was made to assassinate the grand duke and on 7 and 15 August similar attempts against the life of Wielopolski. On 15 Jan. 1863 the revolution broke out and on 22 January all Poles were called to arms. But neither Mieroslavski nor Langievicz or Czekhovski could make headway against the Russians. Wielopolski retired and General Berg, a Russian, was put in his place. The total failure of the revolutionary movement was, however, brought about by Russia's stratagem in winning the Polish peasantry over to its side, for Russia, by a simple stroke of the pen, made these, instead of serf-like toilers of the soil, freeholders of the land they tilled, freeing them of all forced labor (*robot*) and dues to their titled landlords. Thus, in 1864, the whole movement was dying off. Miliutine and Prince Tcherkaski did the Russifying in Warsaw and by a Russian ukase of 26 Dec. 1865 the entire property of the Catholic Church in Poland was taken over by the Russian government and all Catholic religious matters were decided by the Ministry of the Interior at Saint Petersburg. Lithuania was Russified by Muraviov and «Red» Russia likewise. On 22 Dec. 1865 all persons of Polish blood in the nine Russian western provinces were forbidden by an imperial law to acquire landed property. The University of Warsaw was entirely Russified and only Russian forcibly taught at school. Nearly every Polish civil and administrative institution was rooted out. After 1883 General Gourko more than followed the footsteps of his two predecessors, Albedynski and Kotzebue in stamping out Polish life. In July 1884 another conspiracy was discovered and 200 Poles were either executed or deported to the Siberian mines. To prevent the infiltration of Polish ideas a ukase of 21 Jan. 1885 interdicted the purchase of land by Poles in the 10 western provinces of Russia. All intercourse of Poles with the Pope was barred. While all this was going on in Russian Poland, in the Polish provinces of Prussia things veered about a good deal, there being no settled policy pursued by the Prussian government toward the Poles. Generally speaking, under William I the Poles were treated far more liberally than was the case during the reign of the last kaiser, William II. In the main the weapons used were economic and cultural. For sundry periods the teaching of Polish was rendered difficult in the Prussian provinces, and this caused deep dissatisfaction. But Bismarck's pet scheme was to create a huge state fund and to buy up Polish estates and, by breaking these up into smaller holdings, to settle Germans on these lands and thus gradually Germanize the whole of the Polish provinces, more especially Posen. In these efforts, though, he and his successors were but measurably successful. But, on the other hand, Polish resistance grew and Polish counter-measures were taken which frustrated the attempts at Germanization. In a material sense, however, the Polish provinces of Prussia flourished more and more. Their economic wealth increased marvelously. In liquid capital there was, as to them, an increase of 350 per cent between 1846 and 1900, and in immobile wealth the figures were similar. As to the Austrian portion of former Poland, i.e. Galicia, the Poles, owing to Austrian internal political requirements, were practically given a free hand. No repression of any kind was practised there. Polish, in fact, throughout Galicia, was the official tongue, to the detriment of Ruthenian, or Ukrainian, although numerically the latter were slightly stronger than the former. At the University of Cracow, the Polish language and literature were fostered and nurtured most carefully, and in the second university of Galicia, that of Lemberg (Lwow), although situated in the heart of the Ruthenian portion of Galicia, Polish likewise dominated, and Ruthenian was suppressed as far as was feasible. Thus Galicia for a generation or more formed the intellectual rallying point and centre of Polish aspirations, mentality and achievements.

No other European nation was placed in such a perplexing predicament by the World War as was Poland. With her traditional enemies—Germany and Russia—at each other's throats; with the fortunes of war on the Eastern front being determined on Polish territory; and with the Polish question certain to come up at the ultimate peace conference, neutrality was impossible, since to remain neutral meant to jeopardize her claim for independence. But with the different currents and undercurrents of political thought prevailing in the three sections of dependent Poland (Russian, German and Austrian), it was much easier to realize the existence of a golden opportunity than to grasp it properly. While

these varied Polish populations were hesitating as to which side to align themselves with, both Germany and Russia pursued toward them an ingratiating policy, based on good-will manifestos and alluring promises, which but added to their perplexities. In the end the Poles found themselves fighting on both sides. Even the now world-renowned General Pilsudski himself led his Polish legions early in the war to the Eastern front, only to be imprisoned in the German fortress of Magdeburg for insubordination.

As the war progressed it became clear that, despite their promises, neither Austria, nor Russia, nor Germany ever meant to go as far as Polish liberation, and it was only the collapse of all three of these monarchies that made realization of that dream seem possible. Much impetus was given to the Polish cause by such influential propagandists as Dmowski in Western Europe and Paderewski in America. Neither France nor Great Britain, however sympathetic toward Polish freedom, could raise its voice in favor of the independence of a country three-fifths of which belonged to its powerful ally, Russia. But Italy had gone on record as favoring Poland's unconditional independence as early as 1916, while President Wilson anticipated his famous "fourteen-points" plea for a free and reunited Poland in a peace proposal made to the belligerent nations long before America entered the war. The Russian Revolution, particularly the Bolshevist phase of it, and the complete debâcle of the Central Powers convinced Poland that the hour of her freedom had struck, and long before its existence was recognized at the Versailles Peace Conference, the Poles had consolidated a new Polish state. The new Poland was actually born and its independence proclaimed in November 1918.

The organization of this new state, which came into being as a democratic republic, presented many difficulties. Aside from the long series of wars she had to fight in defence of her frontiers, there was also the immense internal task of welding together the three long separated provinces that had drifted as far apart as common social characteristics would permit. To these two immense tasks was added a third—that of reconstructing a country two-thirds of which had been devastated by war.

As indicated above, peace did not come to Poland with independence. The Versailles Peace Conference left her frontiers undetermined at several points, East and West. Hence boundary disputes soon involved her in war with several of her neighboring states—with Czechoslovakia over the former Austro-Silesian Duchy of Cieszyn (Teschen); with Ukrania over Lwow, the principal town of Eastern Galicia; with Lithuania over Vilna; and with Soviet Russia over the Eastern frontier. The last mentioned war lasted two years (1919–21), and threatened the very existence of New Poland. It ended with the Peace of Riga (1921) after a huge Bolshevist army, which had advanced to the gates of Warsaw in August 1920, had been thrown back and routed by an inferior Polish force aided by French leadership and Allied munitions. On 15 March 1923 the Western Powers officially sanctioned Poland's Eastern frontiers, and the era of conflict in regard thereto seems to have come to a close. In this connection mention should be made of Poland's peaceful, though serious, disputes with Germany over the division of Upper Silesia, and the prolonged diplomatic wrangle over military police control in the free city of Danzig.

As turbulent as have been the new state's foreign relations, her domestic history has been scarcely less stormy. It could hardly have been otherwise, in view of the almost complete estrangement of the three Polish provinces, their long divorce from self-government, and the relatively large proportion of non-Poles (fully one-third) included in the country's population, whose rights must be safeguarded under the Polish-Minorities Treaty of 28 June 1919, which placed them under the protection of the League of Nations. New Poland began her self-government virtually as a dictatorship under General Pilsudski, who had been made Commander-in-Chief upon his release from his German prison at the Armistice. Upon Paderewski's return to Warsaw, he was asked to form a Coalition Cabinet, and the Constituent Assembly that met under his rule (February 1919), drafted a provisional constitution, and re-elected Marshal Pilsudski acting Chief-of-State. Paderewski's Cabinet fell, 7 Dec. 1919, marking the beginning of a procession of Cabinets which came and went during succeeding years. In and out of Parliament partisanship ran so high that for three years no constructive legislation was enacted. Even the constitution was not adopted for four years, while on 16 Dec. 1922 Narutowicz, the first President of the Republic, was assassinated by a political fanatic five days after assuming office.

The so-called Polish Revolution of May 1926 (Pilsudski's *coup d'etat*) may have proved Poland's unreadiness for constitutional government. At any rate, Pilsudski's influence remained unimpaired until his death in 1935, despite his rebuke by the Diet on 13 Feb. 1927. In 1939, Chancellor Hitler of Germany demanded the return of Danzig to the Reich and a re-settlement of the Corridor question with Poland. Nazi outbursts against Poland grew in frequency and intensity as the year advanced and by autumn it became evident that war impended. Poland, relying on her mutual assistance pacts with France and Great Britain, stood firm and prepared to offer resistance. In September, 1939, Germany invaded Poland and within six weeks had crushed all effective Polish resistance. The final coup came when the U. S. S. R. sent forces into Poland from the east and occupied the Polish Ukraine and Polish White Russia. A new border, running just east of Warsaw, was set up between Germany and Russia, but Germany overran and took possession of that part of Poland which had been assigned to Russia within a few days after Hitler's armies began their surprise attack on the Soviet Union on 22 June 1941. See SECOND WORLD WAR, Vol. 28, p. 782 et seq.

POLANGUI, pō-läŋ'gē, Philippines, a town in the province of Albay, Luzon, on the Inaya River, 18 miles northwest of Albay, the provincial capital, near the boundary of Ambos Camarines (Sur). Pop. 7,960.

POLAR, or ICE, BEARS. See BEARS.

POLAR CIRCLES, two imaginary circles of the earth parallel to the equator, the one north and the other south, distant 23° 28′ from either pole. The surfaces enclosed by these circles are known as frigid zones.

POLAR CLOCK, a tube, invented by Wheatstone, containing a polarizing apparatus, turning on an axis parallel to that of the earth. It indicates the hour of the day on an hour circle by being turned toward the plane of maximum polarization of the light of the sky, which is always 90 degrees from the sun. See POLARIZATION OF LIGHT.

POLAR DISTANCE, *in astronomy,* the angular distance of any point on a sphere from one of its poles; more especially, the angular distance of a heavenly body from the elevated pole of the heavens. It is measured by the intercepted arc of the circle passing through it and through the pole, or by the corresponding angle at the centre of the sphere. According as the north or south pole is elevated we have the north polar distance or the south polar distance. The sum of the two polar distances of any point is obviously 180 degrees.

POLAR EXPLORATION. See POLAR RESEARCH.

POLAR RESEARCH. Early American exploration in the Arctic divides itself into three parts — the expeditions, 1851–55, incident to the Sir John Franklin search; those promoted by the United States government, 1870–72 and 1881–84, and those projected, financed and led by Rear Admiral Robert E. Peary, U.S.N., 1891–1909. The first American ships to participate in the Franklin search were the *Advance* and *Rescue,* in command of Lieutenant De Haven, which leaving New York 24 May 1850, searched the Greenland coast as far north as practicable, returning late the same year, with no tidings of the lost explorer. Henry Grinnell, a New York merchant, who had given liberally to the work, renewed his offer of aid, and equipping the brig *Advance,* dispatched her from New York, 30 May 1853, in command of Elisha Kent Kane, U.S.N., surgeon of the De Haven Expedition, with John Brooks as first officer and Capt. J. Wall Wilson navigator. The *Advance* wintered in Rensselaer Harbor, on the western coast of Greenland, 78° 37′ N., but, unable to free herself from the ice, was detained a second winter, during which a party retreated about half-way to Cape York, but were obliged to turn back, and on 17 May 1855 the whole company, with their boats, left the *Advance* and after an arduous journey reached Upernavik 9 August. Dr. Kane found no trace of Sir John Franklin, but his explorations by sledge were extensive and the scientific results of his expedition valuable. William Morton, leading one of the sledge parties, reported that at Cape Constitution (82° 27′ N.) on 21 June 1854 he had seen the open Polar Sea, and upon this statement much subsequent discussion was predicated. One death, that of Christian Ohlsen, carpenter, oc-

curred 12 June 1854, in the Kane Expedition, of which the last survivor, Capt. Amos Bonsall, carpenter, died in Philadelphia, 18 Oct. 1915.

In 1860 Dr. Isaac I. Hayes, surgeon of the Kane Expedition, returned to the North in the schooner *United States,* and during the spring of 1861 accomplished a memorable sledge journey, crossing Smith Sound and carrying the flag of his country to Cape Lieber, Grinnell Land, 81° 35′, and losing by death the astronomer of his party, Sonntag, at the head of Foulke Harbor, the winter quarters of the *United States.* In 1871 Capt. Charles Frederick Hall, who had extensive experience, principally among the Eskimos of Labrador and Baffin Land, sailed from New York on the steamer *Polaris,* outfitted and equipped by the United States, and on 3 September went into winter quarters in Thank God Harbor, lat. 81° 38′ N., long. 61° 44′ W. Captain Hall, on 10 October, left on a sledge trip, reaching 82° 2′ N., and on 8 November, after an illness of a few days, died on board the *Polaris,* Capt. Samuel Buddington succeeding to the command. Scientific investigations were continued during the winter, but no extensive field work attempted, and on 12 Aug. 1872 the *Polaris* started south. During the night of 15 October the floe to which the ship had been fastened parted from it, and from that date 19 men, women and children drifted over 1,500 miles, until they were picked up 30 April 1873 off Grady Harbor, Labrador, by the Newfoundland sealer *Tigress.* Captain Buddington and the remainder of the party wintered at Lifeboat Cove, north of Littleton Island and, retreating southward in the spring, were picked up 23 June by the whaler *Ravenscraig* and landed in due course at Dundee, Scotland, a relief expedition under command of Capt. afterward Adm. D. L. Braine, with Lieut. afterward Capt. George W. De Long, of the *Jeannette,* second in command, having made a fruitless search of the Greenland coast and of Melville Bay as far as Cape York.

The United States, participating with the principal European countries in a system of circumpolar weather stations, on 21 July 1881 dispatched from Saint Johns, Newfoundland, in the chartered steamer *Proteus,* an expedition in command of Lieut. Adolphus G. Greely, Fifth Cavalry, U.S.A., which took station at Lady Franklin Bay, Grinnell Land, lat. 81° 44′ N., long. 64° 45′ W., the *Proteus* returning after discharging supplies and equipment. The station, named Fort Conger in honor of the senator from Michigan, to whose efforts it was largely due, was amply equipped, and early in the season Dr. Octave Pavy, surgeon of the expedition, made a sledge journey along the eastern coast of Grinnell Land to its extreme northern point, near Cape Joseph Henry, and other field parties worked in the interior, discovering deposits of coal at Water Course Bay, a few miles from the station. In April 1882 Lieut. James B. Lockwood, accompanied by Sergeant (later General) David L. Brainard and Frederick, an Eskimo, supported by other members of the party, crossed Robeson Channel to the Greenland coast, and on 5 May 1882 reached 83° 24′ 5″, the farthest north then attained by man, and for many years the highest reached by the American flag. On 9 Aug. 1883 the entire party retreated from Fort Conger, and in September went into winter quarters near Cape Sabine, whence they were, on 26 May 1884, rescued by Capt. W. S. Schley, commanding the *Bear* and the *Thetis,* 19 of the party, including Lieutenant Lockwood, having perished from starvation. The scientific work of the Greely party was of the first importance, and its magnetic and meteorological data, all of which were preserved, complete and valuable. A privately equipped expedition, that of the *Jeannette,* under Lieut. George W. De Long, U.S.N., left San Francisco in 1879, and passing through Bering Strait, entered the ice at about the 83d parallel. The *Jeannette* was crushed and sunk on 12 June 1881, when in lat. 77° 14′ 57″ N. and long. 154° 58′ 45″ E., and upon retreating to the Siberian coast in three parties, one boat commanded by Lieut. Charles W. Chipp, U.S.N., was separated from the others, and never again heard of. Captain De Long, reaching the mouth of the Lena Delta, perished from starvation, only two of his party surviving, while the third boat under command of Chief Engineer, the late George W. Melville, U.S.N., reached land in safety without the loss of a man. The British government in 1875 dispatched the *Discovery,* Capt. George Nares, and the *Alert,* Commander Albert H. Markham, by way of Smith Sound to the north, during the following winter sledge parties accomplished much work to the westward of Cape Joseph Henry, carrying the reconnaisance to 75° 30′ W., while a party advanced from Cape Hecla directly over the sea-ice to the Pole to 83° 20′. Both ships were beached during the winter, but were successfully floated the following summer and returned in safety.

Lieut. Robert E. Peary, U.S.N., having, in 1886, made a summer's reconnaissance of the Greenland ice-cap, sailed from New York 6 June 1891 in the *Kite,* accompanied by Mrs. Peary and his own party of five, the expedition being sustained wholly by his private resources and the assistance of a few friends. Establishing winter quarters on the eastern side of McCormick Bay, lat. 78° 10′, long. 69° W., the winter was passed in preparation for the land journey, and on 10 April 1892, accompanied by Eivind Astrup, Peary began his attempt to cross Greenland to the northeast, which ended on 4 July at Navy Cliff, Academy Bay, lat. 83° 27′, long. 61° 10′, where he gained an unbroken and commanding view of the Arctic Ocean, demonstrating the insularity of Greenland, an achievement for which he subsequently received the gold medal of the Royal Geographical Society and the Collom gold medal of the American Geographical Society. Returning in 1893 with a larger party Peary established headquarters at the head of Bowdoin Bay, also an arm of Inglefield Gulf, lat. 77° 43′, long. 63° 10′, where, on 12 Sept. 1893, Marie Ahnighito Peary was born, and in March 1894 renewed his attempt to cross the inland ice-cap and to push his explorations farther to the northward. An unprecedented equinoctial storm and a plague among his dogs frustrated his plans, and on 29 August the party, except Peary, Hugh J. Lee and Mat Henson, returned to the States. In the following spring the three men made a successful attempt to cross again the ice-cap, though failure to recover the provisions cached the previous year, 120 miles from headquarters, was a serious obstacle and compelled return with only

about 15 miles farther north than had been made two years before. In 1896 and 1897 Peary again visited Greenland, bringing home on the former the smaller, and on the latter voyage the larger, the 90-ton meteorite, which had been seen 70 years before by Sir James Ross at Meteor Island, near Cape Sabine, and which had furnished the natives with tools and cutting implements, and is the largest known meteor in the world. Having organized the Peary Arctic Club, of a few of his personal friends, on 4 July 1898 Peary sailed from Saint Johns, Newfoundland, in the *Windward;* wintered in her in Allman Bay, lat. 79° 10′, long. 75° 20′, on the west side of Smith Sound, rectifying and recharting the whole Bache peninsular and Buchanan Sound country, and on 1 Jan. 1899, sledging along the ice-foot, reached Fort Conger, isolated since General Greely's departure 18 years before. In June Peary pushed westward, crossing the divide of Grinnell Land, and looked down upon the open and ice-free sea beyond. Leaving his headquarters at Etah early in March 1900 and Fort Conger, 15 April, he reached "Lockwood's farthest," 8 May, and a disintegrated pack and an open sea preventing further advance to the Pole, rounded the northern end of the Greenland archipelago, discovering the most northern known land in the world, which he named in honor of the president of the Peary Arctic Club, Cape Morris K. Jesup. Pushing his explorations southeastward to 82° 10′, 61° 30′ W., on 21 May Peary saw before him to the south the peaks of Independence Bay, which he had discovered nine years before, realized that the demonstration was complete, and that the mystery which had surrounded the northern end of Greenland for a thousand years had been dispelled. The winter of 1900–01 was passed in the field, near Lake Hazen, Grinnell Land, and on 6 May 1901 Peary joined the *Windward* with Mrs. Peary and Miss Peary on board, which had been ice-bound since the previous September at Payer Harbor, near Cape Sabine. Wintering at Cape Sabine, 1901–02, in February, accompanied only by Matthew Henson and natives, Peary returned to Fort Conger and endeavored to attain the Pole, from Cape Hecla as a point of departure, but on 16 May, at 84° 17′, the highest then attained by the American flag, he was compelled by insurmountable pressure ridges and the condition of the ice to give up the attempt, and returning to Cape Sabine he was met, 5 August, by the *Windward* with Mrs. Peary on board, and reached Sydney, C. B., 15 September, thus concluding 12 years of arduous and most successful work. In the spring of 1906 he succeeded in reaching 87° 6′ north latitude in the *Roosevelt,* or within about 203 miles of the north pole, thus creating another "farthest north" record.

In 1893 Fridtjof Nansen in the *Fram,* specially constructed for the purpose, entered the ice off the northern coast of Asia and for the next three years drifted northward, one of the objects of the expedition having been to demonstrate the theory of the drift from east to west. On 12 March 1896 Nansen, accompanied by Lieutenant Johansen, left the *Fram* in lat. 84° and with dogs and sledges pushed his way over the sea ice poleward to 86° 14′ on 20 May, when farther advance was impossible. Retracing his course Nansen and Johansen finally, without dogs, landed on the northern shore of Franz Josef Land, where in a hut and subsisting upon seal and walrus meat the two explorers passed the winter. While advancing southward on 12 May 1897 they were descried by Frederick Jackson from his headquarters at Cape Flora, and remained with him at his camp until his return the following summer. The *Fram,* under command of Captain Sverdrup, after Nansen's departure, drifted still farther to the north, attaining only 18 miles less than Nansen's highest, and by almost superhuman exertion, was broken out of the ice later in the season, reaching Tromsö but a few days after Nansen. The entire party and ship returned together to Christiania, from which they had departed three years before.

Alfred C. Harmsworth (later Lord Northcliffe), the English newspaper proprietor, in 1892 dispatched an expedition led by Frederick G. Jackson, with Lieut. Albert H. Armitage, R. N., second in command, to Franz Josef Land for a thorough reconnaissance of the archipelago and an advance to the north as far as practicable. The *Windward* remained ice-bound near Jackson's headquarters at Cape Flora for the first winter, and for three succeeding summers visited the station with supplies and reinforcements. The work of Jackson included the charting and mapping of a large portion of the Franz Josef Land Archipelago, though in consequence of unfavorable conditions not attaining a latitude higher than had been previously accomplished. Mr. Harmsworth later presented the *Windward* to Commander Peary.

In 1899, Prince Luigi, Duke of the Abruzzi (q.v.) in the *Stella Polare,* reached Teplitz Bay, Rudolf Land, where the ship was beached and winter quarters established. The following spring the sledge parties led by Capt. Umberto Cagni achieved, on 25 April, 86° 33′, the highest latitude then attained by man, for which achievement both the Prince and Cagni received upon their return gold medals from the Royal Italian Society and recognition by the scientific bodies of the world. Interest in these achievements is increased by the fact that during the Turco-Italian War of 1912, the Duke D'Abruzzi served as commander-in-chief and Captain Cagni as admiral of a division of the fleet operating against the Tripolitan coast, the latter commanding the landing party, and both continued during the great European War, beginning in 1914, to exercise similar commands in the navy of their country. Some other attempts upon the Pole by the Franz Josef Land route have been made by Walter Wellman and Evelyn B. Baldwin, the latter under the patronage of William Ziegler, whose second expedition, led by Anthony Fiala, left Tromsö in July 1903.

Capt. Otto Sverdrup, of the Nansen expedition, sailed in 1899 to Smith Sound in the *Fram,* and after having been ice-bound for the winter of 1899–1900 in Rice's Strait, in the autumn of the latter year entered Jones' Sound, where he remained for the next two winters, pushing a line of the extensive exploration northward and westward by the former of which he practically determined the insularity of Grinnell Land and by the latter carrying the flag of his country to

85° 42′ and definitely mapping much coast which had before been inaccurate or imaginary. Captain Sverdrup's surgeon, Dr. Jensen, died during the first winter in Rice's Straits, but with this exception his entire party, after a diligent and arduous three years, returned to Norway in good health (1903).

The year 1909 was particularly eventful in polar research. Not only was the North Pole actually reached by Commander Peary on 6 April, but all previous Antarctic records were eclipsed by Sir E. Shackleton when he on 9 January came up to within 111 statute miles of the South Pole.

Peary prepared for his sixth and successful attempt to discover the North Pole as early as the summer of 1908, but delay on the part of his shipbuilder prevented an earlier start than on 17 Aug. 1908. His vessel was the *Roosevelt,* and his scientific assistants were as Ross G. Marvin, of Cornell, George Borup, of Yale, and D. B. MacMillan, of Bowdoin. The company included besides, 66 men and 140 dogs. The entire equipment was the very best, and the plan the ripest the experienced explorer could devise. Five separate detachments, each independently equipped and fully provisioned, were to advance a certain distance to relieve or replenish some one of the various divisions at a point definitely prearranged and then return. In this way, one division after another having turned homeward, there remained but a single party to make for the goal.

Setting out from Etah on 17 Aug. 1908, the first objective, Cape Sheridan, was reached on 5 September. There, on the shore of the Arctic Sea, the party wintered. Winter camp was broken on 15 Feb. 1909 and the first of the five detachments proceeded toward Cape Columbia. In accordance with the general plan, relieving parties were met and turned back as soon as their purpose was accomplished. Only five men made the final dash to the Pole—Peary, Matthew A. Henson (Peary's colored servant), and four Eskimos. Five forced marches, under unusually favorable circumstances, brought the long-sought-for goal to view on 6 April 1909. The entire distance from mainland to Pole, 475 statute miles, was covered at the unprecedented average speed of 13 miles per day—a feat which in itself would have made the expedition noteworthy.

Observations gave 89° 57′ just before the party finally halted. During the 30 hours spent there, a temperature of from —12° to —30° F. prevailed at the Pole. For the most part, the sky was clear, and, save for the "chalky" whiteness of its ice, nothing whatever struck the expectant observers. As was anticipated, no life of any kind was found at the Pole. After making all necessary records and photographs, the party planted the American flag to mark the imaginary pole and turned homeward.

The homeward marches, greatly favored by paths and stations made in the outgoing expedition, were made at an average daily rate of 29.5 miles—more than double that of the outgoing average. The *Roosevelt,* which was used also on the return voyage, reached Indian Harbor on 6 Sept. 1909. From there the news of the great achievement was cabled to the world.

Apart from the momentous discovery itself, data of scientific importance were gathered along the way; of these, the most important were the soundings made at intervals, which furnished the first conclusive proof of the vast oceanic depths north of the American Arctic lands. In addition, the existence of large land masses still unknown has become even more doubtful since this expedition.

Rear Admiral Peary submitted to the National Geographical Society his data and proof and its special committee found in them conclusive evidence that he had reached the North Pole on 6 April 1909. See articles on PEARY and COOK, FREDERICK ALBERT.

North Polar Research Since 1909.—Numerous expeditions have invaded the Arctic regions since Admiral Peary discovered the North Pole. On 4 July 1913 the American Museum-Geographical Society-University of Illinois expedition left New York with Crocker Island, which Peary believed he had discried in 1906, as its objective. Its leader was Donald B. MacMillan, who had led a Peary supporting party from Cape Columbia in 1908. The expedition wintered at Etah, from where, in the spring of 1914, MacMillan and Ensign Fitzhugh Green, U. S. N., crossing Ellsmere Land, proceeded far enough out upon the sea ice to establish the fact that Peary had been mistaken; they not only found no land, but no evidences of land. Returning to headquarters at Etah, the winter was devoted to such researches as opportunity offered, pending the arrival of a relief ship. Late in the summer of 1915 Prof. Edmund O. Hovey of the museum, sailed on the auxiliary schooner *George B. Cluett* to bring the MacMillan expedition home, but the schooner was disabled and returned nine months later without having accomplished its purpose. The museum chartered the Danish steamer *Danmark* to gather the scattered members of the expedition. The vessel, however, was hopelessly beset in the ice of Smith Sound, and in August 1917, Capt. Robert A. Bartlett in the chartered *Neptune* brought MacMillan, Ekblaw and Hunt home from the Etah base. Professor Hovey arrived at New York on the same day by way of a Danish mail steamer.

Vilhjalmur Stefansson, whose "blonde Eskimo" expedition brought him into the front rank of Arctic explorers, left Victoria, B. C., in June 1913 in command of the first official Canadian Arctic expedition, more complete in personnel and equipment than almost any entering the North for half a century. The *Karluk,* under Capt. Robert A. Bartlett, accompanied by two auxiliaries, passed through Bering Strait and, in September, while Stefansson with two or three companions was on shore, drifted in fog to sea with the pack. The Southern scientific party, under Dr. Anderson, had been landed before this untoward event. In the following May Captain Bartlett and one Eskimo arrived at Saint Michael's, Alaska, reporting that after three months' drift the *Karluk* had sunk on 27 Jan. 1914 and that the greater part of the ship's party had reached Wrangel Island, from which he and the Eskimo had sledded over the ice to Emma Harbor, Siberia. Leaving the ship before the disaster, the entire scientific staff had perished. Late in the winter the exiles on Wrangel Island were brought home; three had died of illness and exposure. Stefansson remained behind, wintering at Cape Martin and the nearby Eskimo villages, ignorant of the fate

of the *Karluk*. He left the land in March, wending due north, to seek the unknown landmass which years before he had sought under the leadership of Mikkelsen. Stefansson was lost to human ken during the whole of 1914; he returned in 1915 and reported that he had wintered on Banks Island and, in May 1915, had discovered land which human eye had never before seen, in approximately 73.43 N. and 115.43 W. As the season was drawing to its close he retraced his steps, crossed Banks Land after a short stay at his base, where he learned of the loss of the *Karluk*, and immediately chartered the *Polar Bear* with the intention of penetrating to the farthest north winter quarters, whence in the spring of 1916 he proposed to develop the outline and map the land he had discovered. Late in 1917 he returned to his base, and, at Herschel Island, fell seriously ill of typhoid. In the spring of 1918 he made a difficult overland journey by dog-sled to Fort Yukon, whence after months in a hospital he returned to New York and Ottawa.

Two expeditions, depending on the drift of marine currents, were undertaken in 1918. Roald Amundsen from Christiania (now Oslo) in a specially constructed ship, thence to a point on the Siberian Coast, from where he proposed to enter the ice and drift four or five years, possibly to open water or land on the Western Hemisphere; and two of Stefansson's veterans—Storkersen and Andersen—who attempted to drift with the ice westward from a point due north of Alaska to the Siberian Coast.

Donald B. MacMillan in the *Bowdoin* led an expedition to Baffin Land in July 1921 and returned laden with valuable scientific data, adding materially to our knowledge of the distribution and secular variation of the earth's magnetism in Baffin Land and Labrador. On 6 Jan. 1923 Stefansson announced his retirement as an explorer, having spent about eleven years in the Arctic regions. In June 1923 MacMillan led his second expedition in the *Bowdoin* to the North to continue the scientific researches of the previous voyage. He returned after 15 months' absence, bringing back, among other data, information on the Eskimos of northern Greenland and a geological description of that territory. This expedition differed from all of its predecessors in that it was nearly the whole time in touch with the outer world by radio.

An Arctic thrill was given to the world in 1925 when Amundsen and Ellsworth, an American, hopped off from King's Bay, Spitsbergen, on 21 May, in two planes in the hope of reaching the Pole in eight hours. After six hours' flight, they were forced to descend on slushy ice, 680 miles from their base, and after three weeks' heroic labor the six men came back in one of the planes, having been forced to abandon the other. The party confirmed Peary's statement that there was deep water and no land near the Pole. In the same year the Russian government organized an expedition to explore the desert island known as Nicholas II Land, discovered in 1913, but never charted. Undeterred by their failure, Amundsen and Ellsworth determined to make another attempt to reach the Pole by air. Animated by a similar resolve, Commander Richard E Byrd and Warrant Machinist Floyd Bennett, both of the United States Navy, started from King's Bay in an airplane, the *Josephine Ford*, on 9 May 1926, flew in a direct line to the Pole, reached their destination, circled the spot several times, and returned to their base in 15½ hours. Two days later (11 May), the Amundsen-Ellsworth-Nobile Expedition, set out from King's Bay in the Italian-built dirigible *Norge*, sailed over the North Pole as well as the "Ice Pole" and landed safely at Teller, Alaska, after a flight of 71 hours.

In sharp contrast to the success of these two brilliant achievements stands the ill-fated Detroit-Captain Wilkins Expedition of 1926. This was also an aerial venture, planned to fly from Point Barrow, Alaska, across the Pole and then continue to Spitsbergen, a total of 2,100 miles. Haunted by misfortune, Wilkins was compelled to abandon his project. During 1926–27 the Putnam Expedition in the schooner *Morrissey* made voyages of research to Greenland under the auspices of the American Museum of Natural History to establish a weather station for observing meteorological phenomena. Convinced that Norsemen were the first white settlers on this continent, the explorer MacMillan sailed in the *Bowdoin* in June 1927 to verify his theory and to study Punic remains in Greenland, also Eskimo legends and meteorological conditions.

In 1926 appeared the report of the *Maud* expedition under Capt. O. Wisting, which had sailed from Seattle in 1922 and was frozen in at Herald Island nearly two years. In November 1926 the Canadian explorer and naturalist J. Dewey Soper returned with many land and sea specimens, after two years' absence, the first white man to come back alive from crossing Baffin Land.

On 29 July 1931, after a leisurely trip from Germany, the airship *Graf Zeppelin* left Franz Joseph Land for the North Pole. It returned the next day, having been thwarted by dense fog. The scientists on board gathered a large amount of information as to the upper air through the dispatch of small balloons carrying instruments which recorded by radio waves upon instruments on the ship.

On 4 September 1931 the Wilkins-Ellsworth submarine *Nautilus* reported by radio its safe return from a 4-day voyage under the polar ice-fields. In 1937 Soviet scientists established a weather observatory at the North Pole, remaining in residence there, the first human beings to do so. See ANTARCTIC REGIONS—*Exploration;* BYRD, RICHARD E.

HERBERT L. BRIDGMAN,
Revised by HENRI F. KLEIN.

POLARIS, pō-lā-ris, *in astronomy*, the bright star at the tip of the tail of Ursa Minor, now less than 1½ degrees from the true pole, and through the precession of the equinoxes is constantly drawing nearer. The two stars Merak and Dubhe, called «the pointers,» in the constellation Ursa Major always point to the pole-star, and it is thus readily found.

POLARISCOPE, an instrument used for polarizing light and analyzing its properties. See POLARIZATION OF LIGHT.

POLARIZATION OF LIGHT, the effect upon usual light vibration of reflection, refraction, or double refraction. The distinction between polarized and natural light is seen most readily by observing the phenomena of the reflection of a beam of light from the

surface of a plate of glass or any other transparent material. At whatever angle the beam strikes the surface only a part is reflected, the remainder passing into the glass and following a path determinable by the well-known law of ordinary refraction. According to this law $\sin i/\sin r = n$, where i (Fig. 1) is the angle

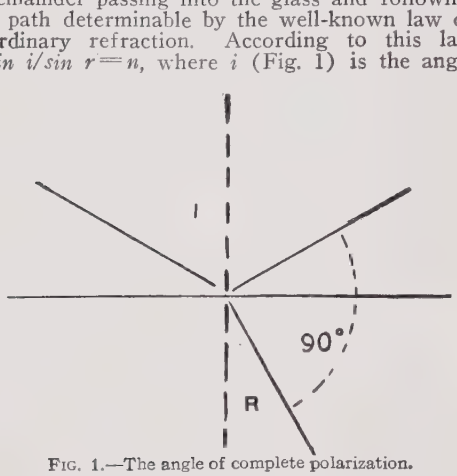

FIG. 1.—The angle of complete polarization.

of incidence, r the angle of refraction and n the index of the glass or other material. The reflected ray, although weaker than the incident ray, appears, if we judge it by many of its ordinary properties, to be precisely similar to the latter. It is not, however, in all respects the same, for if it be again reflected from the surface of glass the reflecting power of this second mirror will be found to depend upon its position. If for example both mirrors be so mounted (Fig. 2) that the angle of incidence for each is about 57 degrees and if the second mirror be turned upon an axis so situated as to permit of its rotation without changing the angle of incidence, it will be found that the second mirror reflects the beam received from the first mirror just as it would any ordinary ray so long as its position is such as not to divert the beam from the plane in which it is first reflected. When, however, in consequence of the rotation, the plane of reflection at the second mirror deviates from that at the first mirror, the proportion of light reflected diminishes. When the angle between these

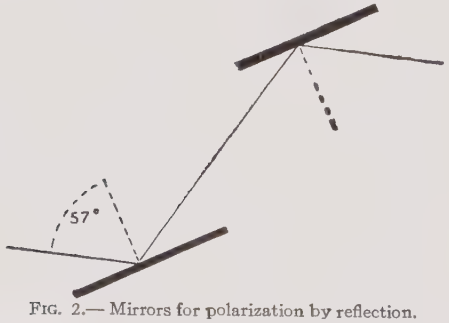

FIG. 2.— Mirrors for polarization by reflection.

two planes becomes 90 degrees no light is reflected from the surface of the second mirror. This striking phenomenon was first noticed by Malus in 1811.

It is clear that the beam of light, as the result of the first reflection, has undergone some modification which renders it incapable of being reflected the second time under the conditions just stated. Light thus modified by reflection is said to be polarized.

In accordance with the accepted theory, light consists of exceedingly rapid transverse vibrations of the luminous ether. These transverse vibrations, the progressive motion resulting from which constitutes the light-wave, are supposed to be rectilinear. When, however, in the case of a beam of unpolarized light, we attempt to determine the plane in which the vibrations take place we find that they appear to occur equally in all planes at right angles to the axis of the wave. This is, indeed, the quality which is expressed by the term *unpolarized* light. This is not strange, however, when we consider that in one second of time about *500 million million* vibrations of the ether have taken place. It is supposed that the plane of vibration gradually shifts so that, in the relatively very long interval of time necessary to produce an effect upon the eye, vibrations will have taken place in every possible plane to an equal extent.

That this shifting of the plane of vibration of light is really very slow appears from the ingenious experiments of Lummer and Gehrcke (*Deutsche Physikalische Gesellschaft,* 1902), who have shown that there is no appreciable shifting of the plane of vibration during an interval of time sufficient to allow of at least 2,600,000 vibrations of the ether. Better to grasp these relations, imagine a vibratory movement with a period of one second. More than 2,000,000 years would then elapse before the number of vibrations would equal that executed in the vibration which causes light in a single second of time. In the case of this slow vibration we should expect to be able to detect a slight change in the plane in which the vibrations take place after about four days. Even with this very gradual shifting of the plane of vibration, however, it is obvious that in the course of 2,000,000 years the opportunities for variation are so great that one would not any longer be able to determine what the original plane of vibration had been.

We may for convenience in considering the effect of reflection on a beam of light regard it as made up of two sets of rectilinear vibrations, equal and at right angles to each other; and that one of these sets of vibrations is in the plane of incidence. When the ray reaches the surface of the glass obliquely the component which is vibrating at right angles to the plane of incidence will have its motion parallel to the surface, while the other vibration will penetrate the surface of the glass. One of these will pass on into the glass while the other will be reflected. The result of reflection, therefore, will be to separate the beam of unpolarized light into two parts and the reflected ray will vibrate in a single fixed plane. Light modified in this way is said to be *plane polarized.* The complete separation of the two components by reflection occurs only at a certain angle of incidence, called the *angle of polarization.* Brewster ('Philos. Transactions,' 1815) discovered that this angle varied with different substances and that $\tan a = n$, where a is the angle of polarization and n is the index of refraction. This relation is fulfilled whenever in a given case the refracted ray makes an angle of 90 degrees with the reflected ray (see Fig. 1). When the polarized

beam reaches the second mirror it will be freely reflected provided the planes of incidence of the two mirrors coincide. When the second mirror is turned so that these planes are at right angles, the ray will penetrate the glass without reflection.

When the theory of light was first developed at the hands of Fresnel, Neumann and numerous other mathematicians, it seemed difficult to determine positively which component of the unpolarized incident ray at the first reflection would be transmitted and which would be reflected. It became customary, therefore, to speak of the plane of polarization rather than of the plane of vibration of the polarized ray; leaving it undetermined whether polarized light vibrated in the plane of polarization or at right angles to the same. The plane of polarization is defined as the plane of incidence. According to the assumptions made by Fresnel, the plane of vibration is perpendicular to the plane of polarization so that it is the component of the incident ray whose vibrations are parallel to the glass, which is reflected.

Some remarkable experiments which afford direct experimental evidence concerning the plane of vibration of polarized light were made by Wiener in 1890 (Wiedemann's 'Annalen,' Vol. 40, page 203). Wiener was able to locate by photographic means the position of the nodes of a standing system of light-waves produced by the interference within a collodion film on glass of the incident and the reflected ray. His interpretation of the results led him to the conclusion that the plane of vibration of polarized light is, as Fresnel had assumed, perpendicular to the plane of polarization.

Polarization by Double Refraction.—Another method by which it is possible to separate a beam of unpolarized light into two polarized components consists in causing the beam to pass through a doubly refracting medium. Many crystals have a structure such that the velocity at which light-waves are transmitted by them depends upon the plane of vibration. A beam of light entering such a crystal is in general resolved into two components, one of which vibrates in the direction which will permit the light to travel with the maximum velocity, the other at right angles to the same. These two polarized beams travel through the crystal independently, the latter being more retarded than the former. If the light enters the crystal obliquely the index of refraction for the two components will differ. The component (O) which is most retarded will be more bent from its original path than the other (E) and will take a somewhat different direction through the crystal (see Fig. 3). If the two polarized

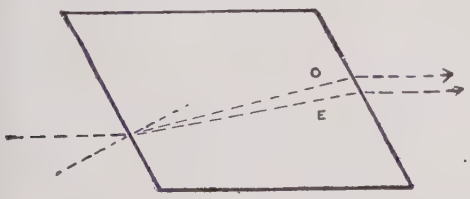

FIG. 3.—Double refraction.

beams thus produced by the action of the crystal leave the crystal through a face parallel to that at which they entered, both will be restored to their original direction and instead of one beam of unpolarized light we then have two beams traveling along parallel paths. The distance between them will depend upon the thickness of the crystal, the angle of incidence and the extent to which the crystal is doubly refracting. If, for example, in the path of a beam of unpolarized light a diaphragm with a circular opening be placed and between this and a screen a lens be mounted in such a position as to produce an image of the diaphragm upon the screen we shall have a circular spot of light at that point on the screen where the image falls. If now in the path of the ray we interpose a rhomb of calcite (Iceland spar) the surfaces of which form an oblique angle with the path of the ray, the latter upon entering the crystal will be bent from its course and divided into two as already described. These upon reaching the screen will form two images of the diaphragm. One of these polarized rays is spoken of as the *ordinary* and the other as the *extraordinary* ray.

To obtain a single beam of polarized light by means of the action of a doubly refracting crystal it is only necessary to interpose a screen which will intercept one and not the other of the two polarized components, or what is more convenient, to devise some way of intercepting one of these rays within the crystal itself. The device usually employed for this purpose was invented by Nicol (1828). The so-called Nicol prism consists of a rhomb of calcite of the form shown in Fig. 4. The rhomb is cut through

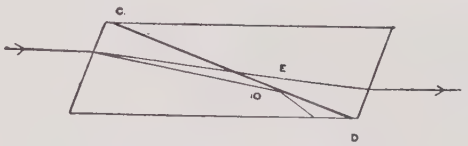

FIG. 4.—Diagram of the Nicol prism.

diagonally at CD and is then cemented together by means of a layer of Canada balsam. The extraordinary ray meets the interface thus produced at an angle which permits its passage while the ordinary ray which is more bent from its course is totally reflected at O and passes out through the side of the prism. In this way a single ray of polarized light the plane of polarization of which is known is obtained. This method of producing polarization has the advantage over the method of reflection that the intensity of the polarized light is nearly half of that of the unpolarized ray. The intensity would be exactly 50 per cent but for the slight losses by reflection at the surfaces and by the absorption within the crystal. Various modifications of the Nicol prism have since been devised by Foucault, Glan, Thompson and others.

By means of certain doubly refracting crystals, of which tourmalin is the best example, it is possible to obtain a single plane polarized ray of light without recourse to any artificial device for the separation of the two rays. Such crystals possess the property of absorbing one of the polarized components much more strongly than the other, so that when light is seen through a layer of moderate thickness a considerable percentage of one of the components is transmitted while the other component is completely absorbed.

The use of tourmalin has the disadvantage that the intensity of the transmitted ray is greatly reduced and that owing to the selective character of the absorption within the crystal the composition of the light is greatly modified. Thus white light transmitted by tourmalin is changed by the almost complete absorption of the blue and violet rays to a yellowish green color.

Polariscopes.—An instrument by means of which the investigation of the properties of polarized light and of the numerous effects obtained with the same is carried on is called a *polariscope*. In its simplest form this instrument consists of two parts. The function of the first, which is called the *polarizer*, is to produce plane polarized light; that of the second to enable one to determine the direction of the plane of polarization of the ray thus produced. This part is called the *analyzer*. The most convenient form of polariscope for many purposes consists of two Nicol prisms P and A, Fig. 5,

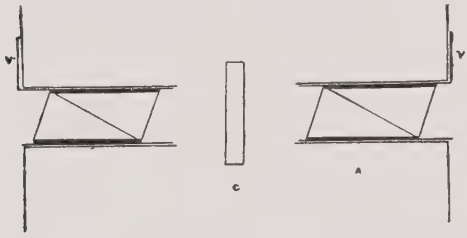

FIG. 5.—Essential parts of a simple polariscope.

mounted in a common axis, each of which is capable of rotation about this axis. The position of the polarizing plane of each of these prisms is indicated by means of a pointer V attached to the prism and moved as the prism is turned around a graduated circle. The polarized ray produced by the passage of light through the first Nicol prism enters the second where it is separated into two components, one of which, the extraordinary, is polarized in the polarizing plane of this prism, while the other is polarized at right angles to that plane. The intensity of these components depends upon the angle which its polarizing plane makes with the polarizing plane of the first Nicol prism. When these two polarizing planes are parallel the *ordinary* component in the second prism becomes equal to zero and the whole of the polarized ray is transmitted, subject only to losses by reflection. As the angle between the polarizing planes of the two prisms increases, the intensity of the extraordinary or transmitted rays falls off and that of the ordinary ray increases until, when this angle reaches 90 degrees, the intensity of the extraordinary ray is reduced to zero and no light is transmitted. Whatever be the angle between the polarizing planes of the two prisms the intensity of the ray transmitted by the analyzer is proportional to $I \cos^2 a$ where I is the intensity of the incident ray and a is the angle between the polarizing planes. When the angle is 90 degrees, so that no light is transmitted, the prisms are said to be *crossed*.

When between the polarizer (P) and analyzer (A) of a polariscope (Fig. 5), with prisms crossed, a layer (C) of any transparent doubly refracting crystal is placed there is restoration of light. Although as already explained the polarized beam from the first prism was unable to pass through the second, the insertion of the crystal between the two prisms has enabled it to do so. The explanation of this beautiful phenomenon is as follows:

The beam of plane polarized light from the first Nicol, which we may suppose to be vibrating in a vertical plane, enters a medium when it reaches the crystal, in which in general light vibrating in two oblique positions at right angles to each other, and in those positions only, is transmitted. The beam then is resolved into two components having these oblique directions of vibration. The light which reaches the analyzer after passing through the layer of crystal is vibrating in these two oblique planes each of which has a horizontal component which is capable of passing through the prism. Not the whole of the light from the polarizer is transmitted by the analyzer, the vertical component of each of the oblique rays being suppressed.

A great variety of crystalline substances, such as quartz, mica, selenite, calcite and indeed all doubly refracting substances, are capable of producing this effect. If the crystalline layer be of proper thickness not only do we have transmission of light but likewise a change of white light into light of other colors produced by the interference of the two components after passage through the second prism. This production of colors by means of a polariscope is one of the most striking phenomena known in optics. The two polarized rays in the crystal, the ordinary and the extraordinary rays, move with different velocities. We have, therefore, emerging from the crystal two similar rays, one of which is somewhat behind the other on account of its greater retardation and which consequently differs from it in phase. So long as these rays have planes of vibration at right angles to one another they cannot interfere, but in the second prism those portions of each which are transmitted are vibrating in the same plane and interference becomes possible. The result of this interference is the destruction of certain of the wave-lengths of which the light is made up. If the incident beam consist of white light that emerging from the analyzer will be white minus the particular constituent or color which has been destroyed by the interference and the beam will have a color other than white. The character of the color of the ray will depend upon the thickness of the crystal layer since it is this which determines the degree of relative retardation of the two components passing through it. If the thickness of the crystal be everywhere the same, the color produced in different parts of it will be uniform, but difference in thickness gives change of color so that the field of view is in many instances most varied and striking.

The effects produced by passing a beam of convergent or divergent light through crystals are still more striking. If plates of crystalline material, placed between the prisms of a polariscope which is provided with a lens for the production of a conical beam of light, are viewed through the analyzer, symmetrical patterns in color the form of which depends upon the character of the crystal and the plane, with reference to its axis, in which the layer has been

cut, are seen. Any detailed description or explanation of these phenomena lies beyond the scope of this article, nor can any idea of the beauty and intricacy of the color-patterns thus produced be conveyed to the mind by words.

Isotropic substances, such as glass, show temporary double refraction, which manifests itself by restoration of light and display of colors between crossed Nicols, when subjected to distortion or stress. Such effects in glass, for example, are produced by compression under a clamp, by bending or twisting, by sudden unequal heating or cooling, or even by setting up standing sound-waves within the substance. Permanent strains, which show themselves in the same way, may be formed in glass by sudden chilling. Blocks of glass thus treated, and known, in French, as *verre trempé*, are among the most beautiful of objects under the polariscope.

Circular and Elliptical Polarization.— When the vibratory motion to which a beam of light is due is capable of being resolved into two components at right angles to each other, of equal amplitude, and differing in phase by a quarter period, the beam is said to be *circularly polarized.*

The actual motion of the ether particles in such a case, could we observe it, would be found to consist of rotation in a circular orbit, either clock-wise or counter clock-wise (looking in the direction from which the wave comes) hence the names, *right-handed circular polarization* and *left-handed circular polarization.*

Circular polarization may be produced by sending light through a crystalline layer of such thickness that the difference of phase of the two rays on emerging is $\pi/2$ (a quarter period). Such a layer is caller a *quarter-wave plate.*

When the difference of phase of the two components differs from $\pi/2$ the emerging beam is said to be elliptically polarized.

Rotation of the Plane of Polarization.— Certain substances have the property of rotating the plane of polarized light which passes through them. Quartz cut perpendicularly to the optic axis possesses this property to a remarkable degree, and many organic liquids possess rotatory power. Such substances are said to be *optically active.* A plane polarized ray upon entering such a medium is converted into two circularly polarized rays, respectively right-handed and left-handed. The resultant of the superposition of these two rays is a plane polarized ray the plane of polarization of which varies with the depth within the layer at which the angle is taken. We may, therefore, think of the plane of polarization as rotating uniformly about the path of the ray.

The rotatory power of solutions of optically active substances depends upon the strength of the solution and this fact has been utilized, in the case of sugar, for determining the amount of saccharine matter present. The instruments employed in this process are special forms of polariscope of great sensitiveness. They are known as *saccharimeters.*

Magnetically Active Substances.— When a beam of plane polarized light passes through a magnetic field in the direction of the lines of force, the plane of polarization is turned.

Looking along the lines of force in the direction in which, by convention, they are assumed to run, the rotation is always clockwise to the observer, whether the light travels with or against the lines. The angle of rotation is proportional to the strength of the field, and to the distance through which the light passes. It depends also upon the medium through which the light moves; being nearly four times as great in carbon-disulphide than in water and more than five times as great in glass as in water. These relations may be expressed by means of the equation $a = \gamma lH$; where a is the angle of rotation, l the distance traversed, H the strength of the field and γ a constant (known as Verdet's constant) which depends upon the character of the medium.

This rotatory power of the magnetic field was discovered by Faraday (1845). To observe it a tube containing carbon-disulphide or water (Fig. 6) is placed between crossed Nicol prisms.

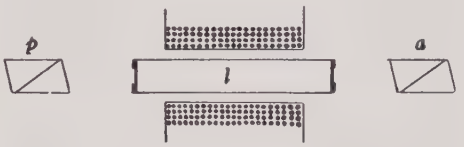

FIG. 6.—Rotation in the magnetic field.

The tube is surrounded by a coil of wire of many turns.

A beam of light is plane polarized by the prism (p), traverses the tube of liquid (l), but cannot pass a, the polarizing plane of which is at right angles to that of p.

When a strong current is sent through the coil, lines of force of the magnetic field thus produced traverse the tube from end to end. Some light now passes through a and the angle of rotation may be measured by turning that prism until the light is again cut off. Upon reversing the current in the coil the direction of rotation is reversed.

EDWARD L. NICHOLS.

POLARIZED HEAT. Radiant heat and light are found to be analogous in their reflection, refraction and absorption. See RADIATION.

POLAROID LIGHT CONTROLS. Polaroid materials afford the world a basic new control over light—a control that makes possible for the first time the limitless production of polarized light. Glareless automobile headlights, three-dimensional motion pictures, antiglare sunglasses, and no-glare desk lamps are but a few of the products either here today or soon to be made possible by Polaroid materials. A new type of double-lensed, Polaroid eyeglass enables the wearer to vary the brilliance of any view. Polarized light was used in the construction of the world's largest telescope at Mt. Palomar, Calif. Textile experts use it to foretell the wearability of cotton fibers. It is used to study the corona of the sun. Sound engineers use it to determine the grain of crystals in phonograph pickups. Insurance companies use it to incrimi-

nate malingerers. It is used as an aid in research for the cure of cancer. It makes possible simultaneous viewing, by a number of observers, of the three-dimensional X-rays that medical men value so highly. In thin film research, it is used to determine the presence of monmolecular layers.

All these and countless other uses of polarized light have been made possible by Edwin H. Land's invention of Polaroid light controls in the early 1920's. An explanation of these controls and their applications will be better understood after the following elementary survey of the nature of light.

Ordinary light travels in a random mixture of wavelike motions at right angles to the direction of travel of the light beam. So long as it is comprised of a mixture of these infinitely many crosswise vibrations in all possible directions, light is unpolarized. But when such an ordinary light beam passes through a polarizing medium—tourmaline, or Polaroid glass—the emerging light contains only those vibrations lying in a single crosswise direction. This light is then recognized as *polarized.*

Since a polarizing medium transmits all light vibrating in a certain crosswise direction, two superposed polarizing media with the same polarizing directions are transparent; with polarizing directions at right angles to each other, they become opaque. This action may be illustrated by visualizing two superposed picket fences with each picket about six inches from the next. When the pickets of the two fences are parallel, it is an easy matter to pass a bicycle tire through them. But when the pickets of one fence are perpendicular to those of the other, it is impossible to pass the tire through. Similarly with the invisible optical pickets of polarizing media. When the pickets of one medium are parallel to those of the other, light is transmitted; when perpendicular, the light is blocked.

That few people are aware of the existence of an abundance of polarized light is due to the fact that polarized light cannot be distinguished from ordinary light by the naked eye. Nature itself polarizes light in three different ways: these are called reflection, scattering, and double refraction. See also POLARIZATION OF LIGHT.

Methods of Polarization.—Polarized light may be readily produced by the reflection of ordinary light from the surface of a clean piece of glass. A beam of light striking a glass plate at an angle of 33°, measured from the surface, is reflected vibrating only parallel to the surface, and hence is completely polarized. The greater the departure from the 33° angle, the less the reflected light is polarized. No polarization occurs when the incident beam is perpendicular to the glass. A similar polarizing action occurs when light is reflected from matte, nonmetallic surfaces such as paper and polished wood. This is the action that makes the polarizing sunglass a unique antiglare device.

Polarization of light produced by the scattering of molecules in the atmosphere is another instance found in nature of light vibrating predominantly in one direction. We shall see later how scattering makes the polarizing camera filter so effective.

Nature's third method of altering the direction of light vibrations, a third polarization method, is called double refraction. This is a phenomenon produced by the majority of transparent substances with the exception of glass. Such substances in their solid form have the peculiar optical property of splitting any entering beam of ordinary light into two emergent beams, polarized at right angles to each other. But natural double-refracting substances with such polarizing qualities are limited in size, quantity, and efficiency; their high cost makes them generally impractical polarizing devices. Other substances are known to produce the related phenomenon of differential absorption; in this case, one of the beams is completely absorbed, while the other is freely transmitted.

History.—The history of polarizing devices reveals that the principle of the control of the direction of light vibrations has been known for centuries. The problem all along has been the practical production of such a control. Identified with the history of the search for a solution to this problem are Batholinus, Christiaan Huygens, Étienne Malus, Dominique Arago, Nicol, Herapath, and other great men in the world of science. Dr. Herapath was the first to discover that sulphate of iodoquinine crystals exhibited qualities of differential absorption, that they polarized light in a way that had never previously been reported. There was only one emergent light beam; it was not discolored. But Dr. Herapath tried in vain to increase the diameter of his microscopic crystals to one-eighth of an inch—a size that he considered tremendous.

It was only when Edwin H. Land attacked the problem with an entirely novel approach that the solution seemed in view; this was more than several hundred years after the phenomenon of light polarization was first recognized. Land reasoned that an assemblage of many of the small quinine crystals would accomplish the same end as increasing the size of one. With this plan, he set about to discover a method of properly orienting the crystals in a stable binder. Contemporaries marvel at Land's achievement—his invention of Polaroid light polarizing material, the first synthetic sheet polarizer that can be produced in theoretically limitless sizes and quantities. Resembling slightly darkened cellophane, it is bonded between layers of cellulose acetate to form Polaroid film, or between glass to form Polaroid glass.

Applications.—Applications of Polaroid light controls are numerous; they fall under five main headings, the first of which is called «control of reflected glare.»

Polaroid day glasses are the outstanding example of the control of the reflected glare of the sun. It will be recalled that reflected light, unless arising from a beam at right angles to the reflecting surface, is comprised of a certain amount of polarized light—light vibrating parallel to the reflecting surface. It so happens that the polarized element is the glare element of reflected light. Since this is the case, Polaroid lenses are placed in the sunglasses in such a way that the glare element of reflected light is completely blocked out, while the vision-giving diffuse element is transmitted through the lenses. In short, where other sunglasses darken equally everything in view, Polaroid sunglasses are discriminating.

Polaroid filters do for the camera what Polaroid sunglasses do for vision. In addition to eliminating unwanted surface reflections in a view, Polaroid filters take advantage of natural

polarization of the skylight. This enables photographers to darken a sky considerably without altering foreground values.

The polarizing ophthalmoscope has proven itself a valuable eye-testing instrument for permitting study within the eye unhindered by reflected glare. Doctors are finding that the ophthalmoscope (q.v.) facilitates accurate diagnosis.

Polaroid desk lamps give glareless illumination by trapping at its source the glare element of reflected light. Since reflected light is comprised of a reflection of the light source predominantly polarized in a direction parallel to the reflecting surface, and diffusely reflected, unpolarized light from the texture of the surface, it is not difficult to quench the specular glare light by filtering the incident light through a Polaroid screen, the polarizing direction of which lies in a plane at right angles to the reflecting surface. In this way, no light vibrations are permitted to strike parallel to the reflecting surface. Hence, glare is prevented by having its essential ingredient removed where the light leaves its source. Polaroid light is most efficient where the object to be viewed and the viewer are in fairly constant positions. For this reason, desk lighting with Polaroid illumination is particularly effective. Polaroid light readily reveals surface details that may otherwise go unnoticed.

The control of apparent light intensity by Polaroid material is the second category of applications. Here, the extinction phenomenon is utilized—the phenomenon of shutting out light by crossing the polarizing directions of two pieces of Polaroid material. The first large-scale application of this principle was made to train windows; here, the turn of a knob enables passengers to control the amount of light entering the car. The same principle is used in Polaroid variable sunglasses; this, of course, enables the wearer to reduce the brilliance of any view by the desired degree. Fade-O-Scopes for amateur motion picture cameras provide the means for making scenes fade gradually on or off the screen. Again the same principle permits the successful examination of fish for parasites or for other imperfections. This method of fish candling saves eyesight, increases efficiency, and is therefore extremely valuable to the fish packer.

The windows of neighboring buildings may one day be made of Polaroid glass with their polarizing directions at right angles. In this way, cross-court privacy is assured. The residents of both buildings will be able to look out into the court, but neither will be able to see into the other's home.

Blinding automobile headlights are held responsible, wholly or in part, for the loss of thousands of lives each year. When Polaroid automobile headlights are released, most of these lives will be saved, for Polaroid glass makes it possible to eliminate headlight glare. One of several possible methods of application is to equip each car with a windshield visor and headlights of Polaroid glass with their optical pickets set at an angle of 45° to the ground. In this manner, light from approaching headlights cannot get through the visors, and all glare is eliminated. Yet, details of the road, pedestrians, and driving landmarks are as clearly visible as if no other car were approaching.

Polaroid color, another product of polarized light, is a phenomenon that has several practical applications. For use in advertising displays, murals, and stage sets, it is a new and startlingly different type of color from any ever previously produced. Polaroid colors are made by inserting a colorless, doubly refracting material like cellophane between two pieces of Polaroid material.

Three-dimensional pictures, both motion and still, are other products that Polaroid promises to bring to the world at large. There are several Polaroid three-dimensional picture processes; of these, the vectographic method is possibly the most interesting and unusual. Ultimately it will make possible the standard production of snapshots, slides, and motion pictures—all with the convincing illusion of depth, the third dimension. For another, three-dimensional vectographic slides and motion pictures can be thrown on a screen by standard, monocular schoolroom or motion picture projectors with no additions or attachments. Finally, the uses of this process are legion. To the naked eye, Polaroid pictures appear blurred; but with Polaroid three-dimensional viewers, they stand out in sharp relief. Depth, roundness, and the solidity of objects in the view are readily apparent.

The analysis of strain, structure, and the composition of matter is still another field wherein Polaroid light controls have made great strides. Medicine and engineering have already felt the impact of these strides.

For over a century, scientists have taught the phenomenon of polarized light to students in classrooms the world over. They recognized it as a powerful tool for research in all the sciences, and as an aid for revealing the fundamental nature of light itself. Certainly a powerful tool, but so costly that few could afford it; so inconvenient that even fewer had the skill and patience to work with it.

Now, Polaroid makes it possible to use polarized light almost as conveniently and inexpensively as ordinary light. Thousands of teachers and research workers are exploring fields that have never been entered before; demonstrating the principles underlying Polaroid headlights, three-dimensional pictures, and other applications of polarized light. Polaroid material is the new means—and the new reason—for teaching the known principles of polarized light.

WIL MARCUS,
Formerly Polaroid Corp., Cambridge, Mass.; now, Columbia Broadcasting System, Inc.

POLDER, pōl'dėr, a name used in Holland and Belgium for a class of agricultural lands consisting of extensive tracts reclaimed by drainage from what had originally consisted of lakes or morasses, and generally lying below the level of the sea. The transformation of the Lake of Haarlem is a striking illustration of what can be effected through energy and patient perseverance. The usual method of procedure in the formation of a polder is to encircle the portion to be reclaimed by an embankment, and construct a canal having its bed sufficiently high to cause a current toward the sea or river. The water is then pumped into this canal by means of various pumping apparatus, worked for the most part by means of

wind-mills, but not unfrequently by steam power. After the water has been drained off, the land is put into the hands of the husbandman, and this kind of soil is in general found to be very productive.

POLE, Reginald, English Roman Catholic prelate: b. Stourton Castle, Staffordshire, 3 March 1500; d. London 17 Nov. 1558. He was the son of Sir Richard Pole, Lord Montacute, by Margaret, daughter of the Duke of Clarence, brother of Edward IV. He was educated at Oxford, where Linacre and Latimer were among his teachers, entered into deacon's orders and received several benefices from Henry VIII, with whom he was a great favorite. In 1519 he visited Italy, and at Padua acquired the friendship of such men as Erasmus, Bembo and Sadoleto. He returned to England in 1525, but in consequence of the affair of Henry's divorce from Catherine of Aragon, withdrew to Paris (1529), under the pretext of continuing there his theological studies. In 1536, in compliance with Henry's order that he should give his opinion regarding the divorce, he drew up an elaborate epistle, 'Pro Ecclesiasticæ Unitatis Defensione,' in which he boldly condemned the divorce as unlawful, and the rejection of the papal supremacy as a breach made in the unity of the Church. This act cost him the loss of all his preferment in England, and he endeavored to form a party against Henry, a design which ended in the destruction of his brother, Lord Montacute, and his aged mother, the Countess of Salisbury, whom Henry sent to the scaffold. Pole was declared a traitor by the king, a price was set on his head and he lived in exile during the rest of Henry's reign. But papal support was given to him, and he was raised to the dignity of cardinal and employed on some important missions. He was one of the three papal legates to the Council of Trent; and on the death of Pope Paul III, Pole came but little short of election as his successor. On the accession of Mary I his attainder was reversed, and in 1554 he returned to England as legate and plenipotentiary of the papal see, and endeavored to secure lenient measures for the reformers and correction of clerical abuses. On the death of Cranmer, Pole, then for the first time ordained a priest, became archbishop of Canterbury, and was at the same time elected chancellor of the universities of Oxford and Cambridge. He undertook to rebuild the churches and to re-establish the ancient discipline, and to a rigorous persecution of Protestants which was instituted he at least assented. His death occurred on the same day as that of Queen Mary, and he was buried in Canterbury Cathedral. Besides several treatises on questions relating to the Church, he wrote 'Liber de Concilio'; 'De Summo Pontifice Christi in Terræ Vicaris,' and 'A Treatise on Justification.' Consult Gairdner, J., 'The English Church in the 16th Century' (London 1903); Haile, M., 'Life of Reginald Pole' (New York 1910); Lee, F. G., 'Reginald Pole' (London 1888); Phillips, T., 'History of the Life of Reginald Pole' (2 vols., Oxford 1764); Zimmerman, A., 'Kardinal Pole: sein Leben . . .' (Regensburg 1893).

POLE, William, English playwright: b. London, 1852. He was manager of Royal Victoria Hall, London, 1881–83, and in 1895 established the Elizabethan Stage Society for the purpose of awakening interest in the Elizabethan drama. Among old plays which he has revived are Webster's 'Duchess of Malfi' (1892); 'Arden of Feversham'; Marlowe's 'Dr. Faustus'; Ford's 'Broken Heart'; Ben Jonson's 'Sad Shepherd' and 'Alchemist'; and 'Everyman.' He has dramatized several novels, among others W. D. Howells's 'Foregone Conclusion' as 'Priest and Painter' (1884), and Baring-Gould's 'Mehalah' (1886).

POLE, (1) *in astronomy,* the name given to each of the two points in which the axis of the earth is supposed to meet the sphere of the heavens. (2) *In spherical trigonometry,* the pole of any circle drawn on the surface of a sphere is one of the points in which the perpendicular to its plane through its centre cuts the sphere. (3) *In geography,* either extremity of the axis around which the earth revolves is called a pole, or a terrestrial pole. The northern one is called the north pole, and the southern the south pole. Each of these poles is 90° distant from every part of the equator. (See EARTH). (4) In *physics,* the points of a body at which its attractive or repulsive energy is concentrated, as the poles of a magnet, the north pole of a needle, the poles of a battery. (5) *In distance,* see PERCH. (6) *In mathematics,* the point from which the radius sector of any point is estimated, in the polar system of co-ordinates.

POLE, Magnetic. See MAGNETISM.

POLE-AXE, an axe attached to a pole or handle of which the length varies considerably. It was formerly used by mounted soldiers, and is yet used in the navy for boarding purposes; in the latter case the back of the axe is furnished with a hook and is called a boat-hook and a boarding-axe.

POLE STAR. See POLARIS.

POLECAT, a small European carnivore (*Mustela putorius*) of the weasel family. It has an elongated body, short legs, long and flexible neck, and blunt muzzle. Its anal glands are large and discharge a fetid liquid of extremely nauseous odor, almost impossible to remove from clothing or any absorbent material upon which it falls. Hence it is known provincially in Great Britain as fou'mart (that is, foul marten), and the term "polecat" has been applied to the American skunk and other stinking animals; "fitch" (or fitchew) is another name. The general habits are those of the fur-bearing animals (*Mustelidæ*) generally, with a special predilection for preying on poultry and game. A domesticated variety of *Mustela* is the ferret (q.v.).

POLEMON, pŏl'ę-mōn, surnamed **PERIEGETES,** Greek geographer: b. Troas, 2d century B.C. He removed to Athens, became a citizen there, and after traveling extensively throughout Greece wrote several geographical works which were especially valuable in that they contained definite information concerning public monuments, inscriptions, paintings, etc., which had hitherto remained unnoticed by geographers. He wrote several polemical works against Timæus and Eratosthenes, and references to his writings are frequently made by later writers, including Athenæus and Pausa-

nias. A list of his works, 26 in number, on both geographical and historical subjects, is given by Clinton in his 'Fasti Hellenici,' iii, 514, but none of these have come down to us entire. The few remaining fragments of his works were collected and published by Preller (1838). Polemon is considered the father of geographical guide books.

POLEMOSCOPE, a stand or frame high enough to rise above a parapet or other similar object, having a plane mirror at top so fitted as to reflect any scene upon another mirror below, and thus enable a person to see a scene in which he is interested without exposing himself. It is of somewhat ancient origin, but the principle has had a modern application to opera glasses and field glass, and, particularly, to the periscope used on submarines in the World War.

POLENTA, a food preparation common in Italy, consisting of semolina or Indian-corn meal, mixed with water, and boiled until it thickens. It is then poured into a dish, where it becomes firm enough to be cut into slices, in which state, after being seasoned, it is eaten.

POLENZ, pō'lĕnts, **Wilhelm von,** German novelist: b. at Castle Oberkunewalde, Oberlausitz, Saxony, 14 Jan. 1861; d. there, 13 Nov. 1903. Studying at the universities of Leipzig and Berlin he fell under the spell of modern ideas. In 1891 he published his first novel 'Sühne' which was followed by a drama, 'Heinrich von Kleist' (1891).

His three greatest works are, 'Der Pfarrer von Breitendorf,' (1893); 'Der Büttnerbauer' (1895); and 'Der Grabenhäger' (1897). In this trilogy the three several influential personalities in the German country community are described — the pastor, the independent farmer, and the lord of the manor. In the first we find the life of a pastor whose inner spiritual nature develops away from outer churchgoing forms, so that he is finally prompted to give up his parish. In the second novel the life of an older type of unprogressive farmer is depicted, whose possessions fall into the hands of usurers and when the situation becomes unbearable, he commits suicide. In the third book the life of a *Junker* is described, who after tasting the pleasures of life in a large city, returns to his ancestral estate and there learns the serious duties and responsibilities of a rich landowner. Among his numerous other writings are the novels 'Thekla Lüdekind' (1900) in which Polenz in an indirect manner deals with the woman question; 'Liebe ist Ewig' (1901); 'Wurzellocker' (1902); 'Lugisland' (1901) is a series of short stories. In 1902 Polenz made a visit to the United States. His impressions of this trip he has given in his book, 'Das Land der Zukunft' (1903). He coined the phrase, "*Das Land der unbegrenzten Möglichkeiten.*" "The land of unlimited possibilities," as applied to America. After his death his brother published a collection of poems from his posthumous papers under the title, 'Erntezeit' (1904). Consult Bartels, A., 'Introduction to the Collected Works of Wilhelm von Polenz'; von Mach, Edmund, 'The German Classics' (Vol. XVII, New York 1914); Stern, 'Studien zur Literatur der Gegenwart' (Dresden 1904, pp. 235–253).

POLHEM, pōl'hĕm, **Christopher,** Swedish engineer: b. Visby, 1661; d. 1751. He was educated at Upsala. Polhem invented a machine for hoisting ore, which proved so successful that the inventor was made director of mine mechanics by the king. In 1694–97 Polhem traveled in England, France, Germany and Holland, everywhere taking special note of all mechanical inventions and improvements. He subsequently invented quite a number of machines for agriculture, mining and transportation and from Charles XII received the commission to construct a canal between the Baltic and the Cattegat. He also invented a minting machine for George I of England and was knighted by his own sovereign.

POLICE, pō'lēs (Greek, *politeia,* government, from *polis,* a city), a judicial and executive system, and an organized civil force for maintaining order and enforcing the laws. There are traces to be found in every organized society of some system of rules for the maintenance of peace and order. At the same time, a system of police in the special modern sense of the term did not exist in ancient times. In Greece it was mixed up with the totality of their institutions. In Rome, not until the time of Augustus do we find the police becoming a special institution, with a numerous staff of various grades of officers. When the barbarians swept across the Roman Empire and obtained the mastery every trace of a regular system of police disappeared, and only when Charlemagne ascended the throne was there a successful attempt made to re-establish anything of the kind. But after the death of Charlemagne everything fell into confusion again. The Normans, established in the north of France, were the first who made stringent police regulations for the assurance of public tranquillity. In France, previous to the middle of the 15th century, the provost of Paris and his lieutenants were charged with maintaining the peace of the city and suppressing vagrancy. The gendarmerie of France was reorganized from the maréchaussée in 1720. It combines both police and military duties. Like the civil police, it is under the control of the Minister of the Interior, but has duties to perform for other ministries. The gendarmes maintain order in the public highways, and give prompt notice of any serious crimes or accidents coming to their attention. In 1854 the Paris police were reorganized on the London plan. The Prefect of Police is appointed by the Minister of the Interior. Paris is divided into 12 arrondissements or wards, and 48 quartiers or precincts. The Commissaire of a precinct is not subject to the administrative control of the Prefect; he combines magisterial and police duties. The French gendarmerie system is widely copied in European and Latin American countries. The police organization of the Continent generally partakes largely of a military character. To prevent crime German and French police keep a careful record of each inhabitant. Inn-keepers must report new arrivals. The police perform the work of taking the census annually. In Russia and China the liberty of the individual depends almost entirely upon the mercy of the police.

In England, from the time of the Saxon kings, there had existed an organization of a partially voluntary character for the repression

of crime, the arrest of criminals, and the maintenance of good order. In 1828 Robert Peel (hence the term "Bobbie," or "Peeler" applied to the British police, at first in derision) secured the passage of a statute creating the Metropolitan Police Force, and leading the way to the adoption of a uniform system for the whole country. The Metropolitan Police Force dates from 1829. Its office is New Scotland Yard, near the Houses of Parliament. There is a Commissioner, under the Home Secretary, who has four assistants, also appointed by the Crown, having charge respectively of the Uniformed Force, Traffic, Criminal Investigation, and Enforcement of Laws, relative to liquor, gaming, etc. There is also a Receiver ranking with the Commissioner and having charge of clerical matters connected with property and finances.

London is divided into four districts in charge of chief constables. Under the latter are the superintendents (35 in number) most of them in charge of divisions embracing from 500 to 1,000 men. In rank follow the inspectors, the sergeants, and the constables. There are, all told, approximately 200 police stations among which the men are ordinarily distributed. Special forces embrace the King's Household Police, detachments at the Houses of Parliament, Royal Mint, Post Office, etc. There are, altogether, connected with Scotland Yard about 20,000 men, of whom nearly half are available for ordinary duty. The annual expense is about £8,000,000 of which £6,000,000 goes for the payroll. The government and city share the expense equally. An area of 700 square miles—15 miles circle from Charing Cross—is covered, embracing some 7,000,000 people. Scotland Yard in reality is a national police force. Local police forces receive inspection. Efficiency is due in large part to the non-political character of the force and the inspection system. From 1893 to 1900 in the Criminal Investigation Department, both the Bertillon and Galton systems were used for identification; now the finger print system prevails.

In the United States, the English system was followed. In 1857 the State Legislature of New York copied the London plan, but in 1870 abandoned it in favor of local control. In New York City, the Police Department is under the supervision of a Commissioner appointed by the mayor for a term of five years; he may be removed by the mayor or by the Governor of the State. He has five deputies, also appointed by the mayor. The city is divided into 17 inspection districts, each in charge of an inspector, and the districts are divided into 93 precincts, each in charge of a captain. There are 68 station-houses, each in charge of a lieutenant, or desk sergeant, who has clerical police, janitorial, and judicial duties to perform. Police work consists of: (1) patrol service and traffic regulation; (2) detective work; (3) plain clothes service in connection with the suppression of gambling, prostitution, and violation of the liquor laws; and crime prevention; (4) business, clerical and recreational services; (5) medical and surgical care of the force. A training school is maintained, and examination for promotion are competitive, including mental, physical and administrative examinations. The New York force consists of about 16,000 persons, of whom 14,153 are patrolmen, 95 policewomen, and 30 patrolwomen. Women are found useful in enforcing laws regarding young girls and children. Police department expenditures in 1925 rose to $38,000,000.

The single commissioner or director as administrator of the police department, department of public safety or whatever bureau includes the police, is a common provision in the United States, as in New York City, Boston, Philadelphia, Detroit, Pittsburgh and Cleveland. He is generally appointed by the mayor, or mayor and council. In Buffalo under the commission form of government, the mayor, elected by the people, is the superintendent of public safety. The Boston police department is under State control, as is that of Baltimore and St. Louis, which latter, however, has a police board.

Police work in counties and small communities in the United States is done by the sheriff and his deputies, and by the town constable or marshall. Some of the States have forces of constables, rangers, and State police. The Secret Service of the United States is in charge of the Treasury Department. See SECRET SERVICE; also CONSTABLE; DETECTIVE; MILITARY POLICE. Consult Dilnot, G., 'Story of Scotland Yard' (1926); Fosdick, R. B., 'American Police Systems' (1920).

POLICE COURT. See COURT.

POLICE DOG, the name generally applied to the native German shepherd dog, which strongly resembles the wolf in appearance, which is commonly called "Police Dog" because of the large number used in night patrol duty by the police forces of German cities and which is known by a variety of names — French Police Dog, Belgian Police Dog, and in England, Alsatian Wolf Dog. In America, prior to the entrance of the United States into the World War, it was known either as the German Police Dog or by its true name, the German Shepherd Dog. In 1918 the American Kennel Club arbitrarily dropped the word "German," naming the breed simply the "Shepherd Dog." This breed is descended from the long-haired dogs of South Germany, six root stocks marking its beginning. It was introduced into America in 1904. The color varies all the way from black to pure white, with perhaps the majority being reddish brown or black and tan. There are three varieties — the smooth coated, the rough coated or wirehaired (very rare), and the long coated (now growing scarce). Consult Bruette, William A. 'The Complete Dog Book' (Cincinnati, 1921).

POLICE AND FIRE ALARM SYSTEMS. The usual police alarm system consists of a bell signal and telephone arranged in boxes at desired locations. Keys to these boxes are held by the policemen on duty, who must report at certain times from these boxes to headquarters by telephone. On the other hand, if headquarters desires to get in touch with the policeman on a certain post, a bell is rung, attracting the party called. This system is, however, not satisfactory, inasmuch as in most cases the sound of the bell, confused with so many other noises of the city, is not heard. Due to the need for something better, within the past few years a combination involving also a visible signal has been installed in various cities, particularly those of Germany, where an elaborate system is to be found. Under this system, which is worked out in detail, the prin-

cipal feature is a green signal lamp that flashes when the policeman on post is wanted.

Closely analogous with the German police-alarm system is the fire-alarm system in general use throughout continental Europe, the chief difference being that the signal lamps are red instead of green. The advantage of the alarm box and telephone to fire headquarters is apparent, in that it permits the department to know immediately and exactly the location of the fire. It is of advantage, however, as is the practice in many places, to dispense with the use of the key to open the box and using a push-button or other handy device instead, for the sake of saving time.

The fire-alarm lamps are, as a rule, about 15 feet above the sidewalk, while the alarm boxes are attached to the fire-alarm posts within easy reach, some four feet, of pedestrians. These boxes are generally provided with a handle or crank, which must be pulled or turned according to directions.

Under the ordinary system it is not unusual for the individual fire alarm to be sent into the central fire headquarters, and from there transmitted to the branch headquarters, with a consequent loss of time. Under the system under description this is avoided, notice of each fire being sent to the nearest fire house and simultaneously to the main or central headquarters.

A fire-alarm system based on the above principles has been installed in the city of Berlin, where the fire apparatus is also operated by electricity. The time saved by such a system is apparent from the fact that it takes but 12 seconds from the time an alarm is sounded until the department is fully under way on the street.

The great extent of the fire losses throughout the country is rarely understood by the public. Yet, in the failure to take ordinary precautions against fire, and in carelessness and faulty construction, losses amounting to $1,500,000 per day are incurred throughout the United States. On the other hand, the fire losses abroad for six principal cities for a period of five years averaged 33 cents per person, as compared with losses of $3.37 per capita in 366 cities of the United States in 1924. American cities are in need of adopting the most urgent measures and of installing up-to-date and efficient methods of fire and police alarm. The necessity is most apparent and will be recognized by all when it is remembered that the cost of adequate protection is but a small percentage of the yearly damage done by fire in each city.

POLICE JUSTICES. See COURT.

POLICE MAGISTRATES. See COURT.

POLICE POWER. No adequate definition can be given of this subject, the courts usually deciding in each case as to its extent. In its general acceptation it means the power of a municipal government to preserve the welfare of the public by prohibiting everything that is contrary to it, and demanding that which is best for its welfare and safety. The proper exercise of police power is merely to regulate the use and enjoyment of property by its owner; it is founded upon the duty of the State to aid in the protection of its citizens. Legislatures have jurisdiction of police power through a federal system of government, and it is delegated by the State to the municipalities throughout the State, and is exercisable only within its limits. Standard laws and the preservation of the public health are one of the most important duties of the police or State municipality, and they have the right to enact such ordinances as may be required for this purpose — such, for example, as preventing the spread of contagious diseases, and, in some instances, compelling vaccination, the killing of diseased cattle, the destruction of improper food products, compelling proper drainage, prohibiting smoking and expectorating where necessary and the regulation of burials. An important function of the police power is to provide safety for the public in regulating places of public amusement and meetings; compelling the erection of fire-escapes, providing for street lighting and to protect the public morals by prohibiting gambling, improper publications, cruelty to animals, prostitution and drunkenness. The municipalities' general welfare is another important function, for example: protection against fire, regulation of buildings and the erection of telephone and telegraph wires, the care of the insane and poor, abatement of nuisances of all kinds and regulation and control of animals. The regulation of certain classes of business enterprises come within police power, for example: theatres, markets, paint shops, warehouses and wharves, or any such business that if unrestricted may become injurious to the public welfare. Police power regulates the practice of law, medicine, surgery, also plumbers and the business of insurance, banking, trust and railroad companies; it is also within their power to regulate the manufacture and sale of articles of food, the prevention of fraud and the hours of labor. The proper limitation of the police power is largely within the discretion of the legislature, but the reasonableness and character of the regulations and whether or not they are consistent with the constitution and proper public policy, are questions for the courts to decide. Police power cannot be exercised for the benefit of particular individuals, classes or for private purposes; it must not be arbitrary or unreasonable in infringing upon the personal rights of persons, and its main object must be for the public good. See POLICE.

POLICY, the name given a lottery or gambling system, common in large cities. A combination of numbers like 4–11–44 is selected by the player who marks his numbers or «guesses» on a slip or ticket, for which he pays a small sum. The lottery drawing of three numbers awards prizes to those persons having guessed correctly. A favorite or common combination of numbers is called a «gig.» The person playing policy stands only a very small chance of winning a prize.

POLICY, Insurance. See INSURANCE.

POLIDORO (CALDARA) **de Caravaggio.** See CARAVAGGIO DA POLIDORO.

POLIGNAC, pō-lēn-yäk, **Jules Auguste Armand Marie,** PRINCE DE, French statesman: b. Versailles, France, 14 May 1780; d. Saint Germain, France, 2 March 1847. He was implicated in a conspiracy against Napoleon in 1804, and imprisoned, but in 1814 escaped to Edinburgh, where the Comte d'Artois, after-

ward Charles X, then was. After the restoration he entered the chamber of peers and in 1820 obtained from the Pope, as a reward for services to the Church, the title and arms of a Roman prince. In 1823 he succeeded Chateaubriand as Ambassador at London; and in 1829 was placed at the head of the new ministry, with the portfolio of foreign affairs. On 27 July 1830 the people were roused to open insurrection by the ordonnances issued on the 25th, and the dynasty of Charles X was overthrown. Polignac accompanied the king to Cherbourg, and then went to Granville, where he was apprehended. The house of peers condemned him to imprisonment for life, but by the amnesty of 1836 he recovered his liberty and fixed his residence in England.

POLIGNAC, Melchior De, French cardinal and diplomat: b. Puy-en-Velay, Haute-Loire, France, 1661; d. 10 Nov. 1741. He was educated for the priesthood and in 1693 was named ambassador extraordinary from France to Poland, for the purpose of detaching John Sobieski from the league with Austria, and drawing him over to an alliance with France. On the death of Sobieski in 1696 he was employed in endeavoring to effect the election of the Prince of Conti to the Polish throne. His intrigues, though successful in securing Conti's election in 1691, were defeated by Augustus the Strong; Polignac was compelled to leave Poland in 1702. He returned to Paris and in 1712 was appointed plenipotentiary to the Congress of Utrecht, and was afterward Minister to the court of Rome. He became cardinal in 1713. Banished during the regency by reason of his intrigues, he was recalled in 1721, and in 1725 was despatched as Ambassador to Rome, successfully performed his task of reconciling the quarreling factions of the Gallican Church and was raised to the archbishopric of Auch. He returned to France in 1732 and thereafter lived in retirement. As a writer Polignac is known by his didactic poem 'Anti-Lucretius, seu de Deo et Natura,' planned to prove the existence of a Supreme Being, the maker and regulator of all things. The ninth book of this work was left unfinished by the author, and the whole poem was not published till after his death. It was later translated into French and Italian.

POLILLO, pō-lē'lyō, a group of islands of the Philippine archipelago, lying to the north of the entrance of Lamon Bay, southern Luzon, and east of central Luzon. The group consists of the chief island Polillo and 21 small islands, lying to the south and east; area of the island of Polillo, 131 square miles; area of the group, 203 square miles. The formation of the islands is volcanic; the soil is good, and the inhabitants are engaged mostly in agriculture and fishing for home consumption. The island of Polillo is mountainous; the central summit is Malolo, from which short ranges extend in every direction toward the coast. The chief town of the group, Polillo, is situated on the west coast on a bay that affords a good harbor. The group, which was included in the province of Infanta by the act of the Philippine Commission of June 1902, was afterward annexed to the province of Tayabas. Pop. 2,164.

POLIOMYELITIS. Also known as *Infantile Paralysis,* or *Heine Medins Disease.* An acute infectious disease, chiefly involving the spinal cord and its membranes, at times progressing into the upper parts of the mid-brain and brain itself. The agent itself has not been definitely isolated (1939) although the disease has been communicated to lower animals (chiefly monkeys) and has been transmitted through a number of generations of these animals. It is believed to be a filterable virus of some kind, in some ways behaving like the filterable virus of the disease known as hydrophobia. The mode of ingress is not definitely known, but the naso-pharynx is supposed to carry it. It is a communicable disease and occurs in epidemic form, some epidemics having almost circled the globe. It is chiefly found in temperate zones, and the epidemics have occurred chiefly in the summer or autumn, though winter and spring epidemics are known. It is frequently confused with influenza, epidemic lethargic encephalitis and certain forms of cerebro-spinal meningitis. It affects children chiefly, but not exclusively.

The attack often begins with mild respiratory or gastro-intestinal disturbances. There are vague neuralgic pains and headaches, there may be increased irritability to light, sounds and touch and in from 24 to 72 hours certain groups of muscles are partially or completely paralyzed. These paralyses are usually very unequally distributed, and whole muscle groups or parts of a muscle are involved. The involuntary structures are also at times involved, causing various trophic or vegetative disturbances. The nature of the changes in the spinal cord and meninges are those of an acute infiltrating inflammation in which the blood supply to the cord may be cut off or the inflammatory œdema cause swelling and pressure upon nerve structures. Thus there results a partial or complete destruction of the nerve structures of the spinal cord which are correlated with muscle function. The large cells of the anterior horns of the spinal cord, which are stations in the pathways for the conduction of motor nerve impulses, seem to bear the brunt of the inflammatory changes, and hence present the most obvious changes which were seen in the old cases. But it must be remembered that the pathology which was described in the older accounts was framed upon the study of the old and long since active cases. The modern study has shown the widespread involvement of the nervous system and also shown that the disease may be traced to other than purely nervous structures, even if the latter bear the brunt of the serious left-over destructions. In certain patients the chief destructions are found in the mid-brain tissues; from these result paralyses of the cranial nerves, particularly of the eye-ball muscles and the muscles of the face.

The course of the disease varies considerably. As a rule its worst effects are present within the first week of the illness. After this comes the long and tedious stages of recovery which going on slowly at first may improve more rapidly and then a very long period, years it may be, of very slow and gradual improvement if the proper kind of treatment is pursued.

The treatment is preventive, palliative and restorative. In the preventive treatment great care should be taken not to come in contact with poliomyelitis cases, especially in the early stages.

As some of those sick from the disease may have it in a very light form special quarantine measures are desirable for these suspects. All children taken sick during an epidemic should be carefully isolated and contacts with others made as light as possible. In the acute stages of the disease it is not known what may be beneficial. Lumbar puncture helps some, ergot help others. The chief reliance is upon a serum obtained from the blood of persons who have experienced the disease and recovered. The recent development of a much stronger serum from the blood of the horse, while still under experimentation, is expected to give physicians a more effective remedy. In the treatment of the chronic phases great care and detailed attention should be given to conscious muscle training. Electricity, massage and other similar types of therapy are usually unavailing. They are for the most part stupid. The sick and partly degenerated muscles must be activated into tonic action through the only kind of stimulus to which the muscles are physiologically accustomed, namely, the conscious wish to perform movements. This type of therapy requires a detailed knowledge of the use of all of the muscles and the correct type of stimulus to bring out its physiological possibilities. Swimming pools, such as those of the White Sulphur development, are important adjuncts in muscle therapy. Consult Jelliffe and White, 'Diseases of the Nervous System.' See MEDICINE, RECENT PROGRESS IN.

POLISH FOWL, a breed of domestic fowls. See POULTRY.

POLISH FRANCISCANS IN AMERICA. A religious community of the Franciscan order of Friar Minors established at Pulaski, Wis., in 1887, through the special efforts of the Ven. Augustin Zeytz, O.F.M., at the request of the Very Rev. Joachim Maciejcyk, O.F.M., the provincial of Galicia, Poland. Through the generosity of Mr. J. J. Hof, a grant of 120 acres of land was secured at Pulaski, in the State of Wisconsin, where three Polish settlements had been started, and on 27 April 1887 the cornerstone of the new monastery of the Assumption of the Blessed Virgin was consecrated. The Rev. Erasmus Sobicinski, O.F.M., of Galicia was appointed the first superior. On 8 April 1889 the novitiate was formally opened and the first candidate was received in the order. From this time the institution grew and developed, under successive directors, Father Erasmus, the first superior, having died 4 Feb. 1890. In 1900 a new residence was opened in Green Bay, Wis., where in 1903 a new large convent was built and dedicated. At Pulaski, 9 Sept. 1901, Seraphic College was opened and the building subsequently enlarged to accommodate the ever-growing number of students. The community numbers among its members 10 priests, 9 professed clerics, 30 professed lay brothers, 7 brothers of the Order and 18 students.

POLISH LANGUAGE. The Polish language is one of the Slavic family of tongues and is most nearly related to the Bohemian branch of that family. It belongs to the western group of those languages and is spoken by about 15,000,000 people, in its various dialects. Remarkable for its phonetic richness, Polish contains 10 vowels and 35 consonants. The alphabet is the Latin, diacritic marks and combinations being used in addition. The principal peculiarities of pronunciation are the following: *c* is pronounced like *ts* in English; *ch* is a strong guttural, as in German; *cz* is pronounced like *ch* in English; *rz* has a sound compounded of that of *r* and the sound of *z* in the word azure, sometimes almost the same as the latter sound alone; *sz* is pronounced like our *sh; w* has the sound of *v*. The consonant *ć* has a sound absolutely peculiar to the Polish language: it resembles that of *t* followed by or combined with a very soft *sh*. The barred *l* (*ł*) has a sound common to the Polish with other Slavic tongues: it is produced by sounding the letter *l* with the point of the tongue firmly pressed against the teeth. The result is a sound approaching that of *w*. as the *l* in *talk*. Among the vowels *e* and *a* are pronounced respectively like the French semi-nasals *in* and *on; i* has the sound of *i* in the English word pique; and *y* has a sound resembling that of the German *ü*. The tonic accent in Polish words is nearly always on the penult.

The Polish is a highly inflected language. There were formerly three numbers, but the dual has been preserved only in the Masovian dialect. There are three genders, masculine, feminine and neuter; and seven cases, the nominative, genitive, dative, accusative, vocative, instrumental and locative or prepositional. The diminutives and augmentatives are numerous. The inflections of the verbs indicate not only person and number without the aid of personal pronouns as in Russian, but also the gender of the person speaking, and the person spoken about. The great variety of inflections in Polish permits the extensive use of inversion in the structure of sentences.

The principal dialects of Polish are the Masovian or Mazurian, spoken in the districts around Warsaw and in east Prussia; that of Great Poland, which is spoken chiefly in the districts around Posen, Gnesen and Kalisz; the Silesian spoken to the east of the Oder; the Cracovian or the dialect of Little Poland; and the Polish-Lithuanian as distinguished from the Lithuanian proper the language of some of the greatest Polish writers. Consult Polish dictionaries by Booch-Arkossy, F. (Polish-German, 2 vols., Leipzig 1893 and 1899); Chodzko, A. E. B. (Polish-English 1884); Dictionary by seven Polish scholars (2 vols., Vilna 1856–61); Karlowicz and others (Warsaw 1900–); Kierst and Callier (English, Leipzig 1906); Linde (6 vols., Lemberg 1854–60). Standard grammars include those of Malecki (ib. 1863) and a 'Comparative Historical Grammar' by the same (ib. 1879); Krynski (Warsaw 1903); Malinowski (Posen 1870); Morfill (London 1884); Kalina (Lemberg 1883); Manassewitsch (Vienna 1892); Poplinski (1901); Smith (1864); Vymazal (in German, Brünn 1884).

POLISH LITERATURE. Comparatively nothing is known of the Polish language previous to the 15th century. No literary remains in Polish have come down to us previous to that time. For the 15th century itself we have only the 'Florian Psalter,' 'The Song of the Virgin Mary' (Bogorodzico), 'Queen Sofia's Bible,' 'Jadwiga's Prayer Book,' and some Polish sentences in court de-

crees and town documents. But we have for that period the first Polish grammar, by Jacob Parkosz (+1455), in which the first attempt was made to stabilize the language. Whatever literary activity existed in Poland previously and for some time afterward, found its expression through the Latin language. The oldest author, who wrote in the first half of the 12th century, was Martin Gallus, the chronicler. Cholewa (+ 1166) wrote the mythical history of Poland in the form of a dialogue; Kadlubek (12th and 13th centuries), Bogufal, Baszko, Polak, Janko of Czarnkow were historians before Jan Dlugosz (1415–1480), the most famous of all the Polish historians. From the 13th century on there were many scientists in Poland, such as the physicist Ciolek, the humanist Gregory of Sanska, the astrologer and medical writer Glogowczyk, and many others who wrote in Latin. There was also a considerable number of famous preachers, such as Laskarysa, Nicholas of Blon, Vincent Kol.

In the 16th century Polish literature develops by leaps and bounds and soon reaches the Golden Age. The religious and political questions of the day, arising from the conflict of Catholicism and Protestantism, brought into the field a very large number of writers, such as Wujka, Orzechowski, Modrzewski. One of the most famous orators was Peter Skarga (1536–1612), and among the historians of the time are Peter Bielski (1495–), his son Joachim Bielski (1540–), Stryjkowski (1547–), who wrote in Polish, and Matthew of Miechow (+ 1513), Kromer (1512–1589), Gwagnin (+1614), Bzowski (1567–1627), who wrote in Latin. Among the scientists the first place belongs to Nicholas Kopernik, who wrote in Latin. In the belles lettres we start at once with a poet of the first order, Nicholas Rej (1515–1577), whose 'Personal View on the Life of an Honorable Man' enjoyed great popularity. Górnicki (1527–1603) dealt with the political troubles of the time, wrote his 'The Courtier,' which was based on Castiglione's 'Il libro del cortegiano,' and translated Seneca. Kochanowski (1530–1584) wrote political satires and a large number of elegies and epigrams, which had a great influence, not only by his trenchant criticisms of conditions, but also by shaping the language into a perfect instrument of expression. Other poets were Klonowicz and Szymonowicz, who wrote both in Polish and Latin, the three Kochanowskis and Zimorowicz, who wrote in Polish, and Krzychi, Jan Dantyszek, Janicki, who wrote in Latin. The satire took a peculiar turn in the 16th century. In the village of Babin a landed proprietor and a judge formed a «Babin Republic,» in which prattlers were proclaimed as statesmen and other officers were lauded in proportion to the incumbent's incompetency. The Polish kings took interest in the humorous republic, and the Latin writings of the Babin republic exercised quite an influence on the politics and the literature of the time.

The second period, which lasted through the 17th and half of the 18th century, is one of decay, and is known as the «macaronic, panegyric, scholastic» period, when the language itself was degraded by «macaronism,» that is, a senseless surcharging with Latin terms, which was a reflex of the confusion of ideas prevailing in political life. This period abounds in private memoirs, where chronicled events mingle with quasi-philosophic reflections. One of the sanest among these men, who wrote in Polish, was Starowolski (1588–1656); others were Pasek, Jerlicz, Andrew Fredro. Among the Latin chroniclers must be mentioned Piasecki (1586–1649), Albrecht Radziwill (1580–1656), Zaluski (+1711). Mlodzianowski (1622–1686), a Jesuit priest, excelled in the elegance of diction in a time which was rather poor in orators. Among the poets we have Twardowski (+1660), the most prolific versifier of contemporary events in the 17th century, Opalinski (1609–1656), who wrote chiefly satires, Waclaw Potocki (1622–1695), chiefly known for his epic, 'The Chocim War,' in which the language reminds one of the purity of the previous period, Kochowski (1633–1699), the official chronicler of John III, who also left a large number of Polish and Latin verses, mainly of a religious nature, Jerome Morsztyn (+1655), who stood under French influence and preferred satire, Andrew Morsztyn (1620–1700), a cousin of the former, who still more followed the French models, and also translated Corneille's *Cid* and the works of Tasso, Stanislaw Morsztyn (1630–), who translated Seneca and Racine, Elizabeth Druzbacka (1687–1760), one of the first Polish authoresses. The most famous of the poets who wrote in Latin was Sarbiewski (1595–1640), and there was a whole host of Latin panegyrists, who hardly deserve mention. The drama barely made a beginning, but none was good enough to survive.

The third period was one of regeneration and lasted until the appearance of Mickiewicz in 1822. In politics, Karwicki, Leszczynski and Jablonowski advocated a much more sober attitude than had existed in the time of political anarchy, and their view had much to do with reshaping Polish literature. Konarski (1700–1773) did probably more than anyone else to bring reason back to literature, and much was done to improve and settle the literary norm. Among the grammarians must be mentioned Kopczynski (1735–1817) and Mrozinski (1784–1839), while Linde (1771–1847) produced his enormous Polish dictionary in six volumes, the forerunner of Grimm's German dictionary and still the object of admiration of philologists.

We get now for the first time historians, as against the chroniclers of the previous period. Lojko (1717–79) wrote three volumes of 'Polish and Lithuanian Institutions' and a large number of historical essays. Albertrandi (1731–1808), an Italian by birth, wrote much on Wladyslaw Jagiello, the Casimirs, and Polish history in general. Naruszewicz's (1733–96) 'History of the Polish People' was a model for many historical writers. Other historians were Waga (1739–1801), Bandtke (1768–1835), Golebiowski (1773–1849), and documents were collected and discussed by Kitowicz, Wybicki, Niemcewicz, Kozmian, Kilinski and others. Mention must also be made of the political writers of the Four Years' Diet, Kollatay (1750–1812), Staszyc (1755–1826). Nor was there any lack of orators, in whom Poland had before abounded. We have Soltyk, Count Casimir Sapieha, Count Adam Czartoryski, Matuszewicz and the preacher Lachowski and Woronicz. The arts flourished

and in 1816 Czerwinski was able to write 'A History of Polish Civilization and Learning from the Tenth to the End of the Seventeenth Century.' We have also the literary historians Chrominski (1759–1810), Ossolinski (1748–1826), Bentkowski (1781–1852), Count Osinski (1770–1842).

The first poet of this period is Trembecki (1725–1812), who stood under the influence of Voltaire, and was interested in poetry just for poetry's sake. Wegierski (1755–1787) imitated Boileau and other foreign authors in his love lyrics. Krasicki (1735–1801) wrote mostly in a satirical vein. He gained his first reputation by his 'Fables,' wrote a 'Mouseid' and similar poems, several prose tales, and translated Ossian, Lucian and Plutarch. Naruszewicz, who has already been mentioned as a historian, wrote fables, satires, idyls and odes, translated Tacitus and composed two tragedies, 'Guido' and 'Tancred.' Karpinski (1741–1825), a court poet, wrote pseudo-classic idyls and religious songs of a more substantial value. Kniaznin (1750–1807), too, wrote to please the courtiers, but his 'Centennial Celebration of the Victory at Vienna' has more real worth. He translated Lafontaine, Ossian, Anacreon, wrote idyls in the style of the German Gessner, and a number of historical dramas. A more sterling poet was Woronicz (1757–1829), whose larger works, 'Asarmot,' 'Lech,' 'The Wislica Diet' were never finished, and whose 'Hymn to God' is the only one that has escaped oblivion. Niemcewicz (1757–1841) wrote a large number of dramas, among which the comedy, 'The Ambassador's Return,' is probably the best. He lived a long time in America, where he had come to join Kosciuszko. After his return to Poland he wrote some historical poems and devoted himself to historical studies, 'The Reign of Sigismund III,' 'Memoirs of Ancient Poland' and others. He also wrote his own memoirs and a number of novels, among which 'Jan of Teczyn' is probably the best. With him begins the Polish novel. Other poets of this period are Kozmian, Godebski, Keklewski, Morawski. The number of dramatic writers during this time is very great. The mediocre attempts of Princess Radziwill (+1753) and Bogomolec (1720–90) were soon followed by the successful adaptations from Beaumarchais and Molière, by Zablocki (1750–1821), who satirized the negative sides of Polish society. Boguslawski (1760–1829) began his dramatic career by translating for the stage; then he became the founder and manager of the Warsaw Theatre, when he wrote his best original drama, 'The Cracovians and the Mountaineers,' in which he introduced folksongs. Other dramatists were Wezyk, Felinski, Dmuszewski, Prince Czartoryski.

The Romanticism of the West naturally affected Polish literature as well. As in Germany, so in Poland, collections of folksongs appeared in the beginning of the 19th century, such as by Zaleski, Wojcicki, Pauli and a little later, the monumental collection in dozens of volumes by Kolberg. With the growth of the new movement the pseudo-classicism which had prevailed heretofore came to an abrupt end. Brodzinski (1791–1835) stirred up a discussion in 1818 by his review of 'Classicism,' and himself set the example for a new movement by his heartfelt lyrics and still more with his lectures on esthetics, which he began in 1822. He is chiefly remembered for his idyl 'Wieslaw,' in which he introduced scenes from peasant life, and is considered as the forerunner of the great Mickiewicz. The romanticism brought to the front the writers of the Ukraine, the last stronghold of a romantic past, such as Malczeski (1792–1826), Goszczynski, Zaleski, Padura, Grabowski, Groza. Malczeski (1792–1826) wrote an epic, 'Maria, a Ukrainian Story'; Goszczynski (1803–76) is best remembered by his poem, 'Saint John's Feast,' which deals with the life of the Tatra mountaineers, and a number of ballads; many of Zaleski's (1802–86) lyrical poems have been set to music. These poets were far surpassed by the Lithuanian Adam Mickiewicz (1798–1855).

Mickiewicz gained his first reputation by some romantic ballads, 'The Switez Maid,' 'Lilies,' and with his epic 'Grazyna' and 'The Wake' accentuated the quarrel between the classicists and romanticists. Probably the best of his ballads is 'The Three Budryses,' though 'Mrs. Twardowska,' 'The Little Fish,' and many others are of an equally high order. A nine months' stay at Odessa was productive of a series of love songs in the setting of the Tartar Crimea. In 1834 there appeared his famous epic 'Pan Thaddeus,' in which he treated the romantic episode of Lithuania's last raid to enforce a legal decision. The remaining days of his life were dimmed by a deep mysticism.

The period was particularly rich in poets. Count Krasinski's (1812–59) greatest work is his 'Undivine Comedy,' a highly imaginative poem; Slowacki (1809–1849) produced three dramas in verse, 'Kordyan,' 'Mazeppa,' 'Balladyna,' and a number of poetical stories; Garczynski (1806–1833) wrote fiery sonnets of war; of Pol's (1807–1872) many songs, probably his 'Sing of Our Land,' written at Mickiewicz's request, excels for simplicity of diction and warmth of feeling; among the other lyrics of the time must be mentioned Gaszynski, Morawski, Witwicki, Jaskowski, Wasilewski, Lenartowicz, Ujejski, Romanowski, Balza, Grudzynski. Not less numerous are the epic poets. Syrokomla (1823–62) treated sentimentally the history connected with his native home on the Niemen and also tried himself in the drama and translated the Latin poets of Poland into Polish. Zielinski (1809–81) wrote an epic, 'The Kirghiz,' based on his banishment to Siberia. Other poets of this class are Zmorski, Bielowski, Falenski, Odyniec, Chodzko, Kòrsak. Kaminski (1777–1855) was the first one to change the state into a national institution, and at the same time Alexander Fredro (1793–1876) and his son John Alexander Fredro (1829–) produced for it a large number of comedies. Other dramatists were Korzeniowski, Magnuszewski, Anczyc, Balucki, Asnyk and many more.

The novel first found its expression in Rzewuski's 'The Memorable Deeds of Master Seweryn Soplica' (1839), after which Chodzko (1795–1861) produced his 'Lithuanian Pictures,' while Skarbek (1792–1866), Wojcicki (1807–79) and a large number of others enriched Polish literature with their excellent stories, but the

palm for productivity and manysidedness belongs to Kraszewski (1812–), who accomplished the phenomenal deed of writing not less than 700 volumes in every imaginable line of literary endeavor. Among the distinguished historical writers must be mentioned Lelewel, Morawski, Moraczewski, Siemienski, Schmitt, Szajnocha, Liske, Szujski, while the history of literature is represented by Bentkowski, Wiszniewski, Lukaszewicz, Nehring; the history of language by Malecki; bibliography by Estreicher. There is not a line of literary work which does not count some eminent authors.

The last quarter of the 19th and the beginning of the 20th century continue the activities so auspiciously begun a century earlier. Comte's positivism during this time finds its expression in Swietochowski's historical essays, while in the novel its representative is Eliza Orzeszko, who appears as the advocate of progress and science. Others belonging to this school are Zacharjasiewicz, who described the dark sides of bourgeois life; Jez, who gave sketches of the Yugo-Slavs; Balucki, who championed the lower middle class. The greatest poetess of this period is Konopnicka, but the period is particularly rich in poets,—Brzozowski, Jankowski, Urbanski, Gomulicki and others. Sienkiewicz, too, had begun his career as a positivist, but when this fell into disrepute he turned his attention to the past, producing the famous trilogy, 'By Fire and Sword,' 'The Deluge,' 'Pan Wolodyjowski.' Among his very many novels dealing with antiquity, probably none gained such wide recognition as his 'Quo Vadis.' Positivism finds its last adepts in Prus, some of whose novels have been widely translated.

With Wietkiewicz's study, 'Our Art and Criticism,' naturalism makes its entry into Polish literature, and to this school belong Dygasinski, Zapolska, Sever, Reymont, while Zeromski and Sieroszewski may be denominated as impressionists. Meanwhile Cracow develops a school of modernists, among whom excel Lieder, Komornicka, while Szczepanski gathered together all these forces in 'Zycie,' a periodical founded by him in 1897. The number of talents in this group is very large. In addition to the names just given may be mentioned Tetmajer, Rydel, Zulawski, Perzynski, Mirandolla, Lada and later Przybyszewski, Laskowski, Kondratowicz, Soltan. This modernism deteriorated into decadence, but amidst it blossomed the poets of might, Orkan, Danilowski, Micinski, who sing of loftier ideals. It is hard to foretell what the regeneration of Poland has in store for it in literature, but the extremely rich immediate past presages a brilliant future.

Bibliography.— For a historical study of the Polish language consult the publications of the Cracow Academy of Sciences, and the works of Kaluzniacki, Leciejewski, Nehring, etc., and for grammar the works of Brückner, Krynski, Malecki, Matusick, Ulaszyn; for the dialects, Karlowicz, Dembowski and Blat. The Polish-English and English-Polish dictionaries of Rykaczewski (London 1849), Chodzko (Berlin 1874), Kierst (Leipzig 1896), will be found useful, while for a Polish-Polish dictionary Karlowicz's 'Slownik jezyka polskiego' (still in process of publication) will far surpass the excellent older one by Linde (Lwow 1854–60). In German we have the works of Brandes, 'Polen' (also in English, London 1903), Brücknear, Kurtzmann, Lipnicki, Nitschmann, Weckowski and in English, N. Forbes, 'Polish Literature,' a lecture (London and New York 1911); E. C. M. Benecke, 'More Tales by Polish Authors,' (New York 1916); Dyboski, R., 'Modern Polish Literature' (Oxford 1924).

LEO WIENER.

POLISH SUCCESSION WAR, a conflict arising in 1733 from the contest for the Polish throne, between Stanislas Leszczynski and Augustus III of Saxony. See POLAND.
